- Different data sets can result in different algorithms being called. The difference can cause the behavior of your program to vary for each execution. In cases where your code behavior differs greatly between executions, PGO may not provide noticeable benefits. If it takes multiple data sets to accurately characterize application performance then execute the application with all data sets then merge the dynamic profiles; this technique should result in an optimized application.

You must insure the benefit of the profiled information is worth the effort required to maintain up-to-date profiles.

Profile-Guided Optimization (PGO) Quick Reference

Profile-Guided Optimization consists of three phases (or steps):

1. Generating instrumented code by compiling with the \texttt{-prof-gen} (Linux* OS and Mac OS* X) or \texttt{/Qprof-gen} (Windows* OS) option when creating the instrumented executable.

2. Running the instrumented executable, which produces dynamic-information (.dyn) files.

3. Compiling the application using the profile information using the \texttt{-prof-use} (Linux and Mac OS X) or \texttt{/Qprof-use} (Windows) option.
The figure illustrates the phases and the results of each phase.

See Profile an Application for details about using each phase.

The following table lists the compiler options used in PGO:

<table>
<thead>
<tr>
<th>Linux* and Mac OS* X</th>
<th>Windows*</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>-prof-gen</td>
<td>/Qprof-gen</td>
<td>Instruments a program for profiling to get the execution counts of each basic block. The option is used in phase 1 (instrumenting the code) to instruct the compiler to produce instrumented code for your object files in preparation for instrumented execution. By default, each instrumented execution creates one dynamic-information (dyn) file for each executable and (on Windows OS) one for each DLL invoked by the application. You can specify keywords, such as -prof-gen=default (Linux and Mac OS X) or /Qprof-gen:default (Windows). The keywords control the amount of source information gathered during phase 2 (run the instrumented executable). The prof-gen keywords are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Specify default (or omit the keyword) to request profiling information for use with the prof-use option and optimization</td>
</tr>
</tbody>
</table>
Effect when the instrumented application is run (phase 2).

- Specify `srcpos` or `globdata` to request additional profiling information for the code coverage and test prioritization tools when the instrumented application is run (phase 2). The phase 1 compilation creates an SPI file.
- Specify `globdata` to request additional profiling information for data ordering optimization when the instrumented application is run (phase 2). The phase 1 compilation creates an SPI file.

If you are performing a parallel make, this option will not affect it.

Instructs the compiler to produce a profile-optimized executable and merges available dynamic-information (dyn) files into a `pgopti.dpi` file. This option implicitly invokes the `profmerge` tool.

The dynamic-information files are produced in phase 2 when you run the instrumented executable.

<table>
<thead>
<tr>
<th>Linux* and Mac OS* X</th>
<th>Windows*</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>prof-use</code></td>
<td><code>/Qprof-use</code></td>
<td>when the instrumented application is run (phase 2).</td>
</tr>
</tbody>
</table>

If you are performing a parallel make, this option will not affect it.

Instructs the compiler to produce a profile-optimized executable and merges available dynamic-information (dyn) files into a `pgopti.dpi` file. This option implicitly invokes the `profmerge` tool.

The dynamic-information files are produced in phase 2 when you run the instrumented executable.
If you perform multiple executions of the instrumented program to create additional dynamic-information files that are newer than the current summary pgopti.dpi file, this option merges the dynamic-information files again and overwrites the previous pgopti.dpi file (you can set the environment variable PROF_NO_CLOBBER to prevent the previous dpi file from being overwritten).

When you compile with prof-use, all dynamic information and summary information files should be in the same directory (current directory or the directory specified by the prof-dir option). If you need to use certain profmerge options not available with compiler options (such as specifying multiple directories), use the profmerge tool. For example, you can use profmerge to create a new summary dpi file before you compile with the prof-use option to create the optimized application.

You can specify keywords, such as -prof-gen=weighted (Linux and Mac OS X) or /Qprof-gen:weighted (Windows). If you omit the weighted keyword, the merged dynamic-information files are not weighted.

<table>
<thead>
<tr>

</table>
Effect

Windows* and Mac OS* X | Windows* | Effect
---|---|---
(dyn) files will be weighted proportionally to the length of time each application execution runs. If you specify the weighted keyword, the profiler applies an equal weighting (regardless of execution times) to the dyn file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally.

When you use prof-use, you can also specify the prof-file option to rename the summary dpi file and the prof-dir option to specify the directory for dynamic-information (dyn) and summary (dpi) files.

Linux:

- Using this option with -prof-func-groups allows you to control function grouping behavior.

Disables function splitting. Function splitting is enabled by the prof-use option in phase 3 to improve code locality by splitting routines into different sections: one section to contain the cold or very infrequently executed (cold) code, and one section to contain the rest of the frequently executed (hot)
<table>

</tr>
</tbody>
</table>

Refer to Quick Reference Lists for a complete listing of the quick reference topics.
Profile an Application

Profiling an application includes the following three phases:

- Instrumentation compilation and linking
- Instrumented execution
- Feedback compilation

This topic provides detailed information on how to profile an application by providing sample commands for each of the three phases (or steps).

1. Instrumentation compilation and linking
   
   Use `-prof-gen` (Linux* and Mac OS* X) or `/Qprof-gen` (Windows*) to produce an executable with instrumented information included.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and Mac OS X</td>
<td><code>ifort -prof-gen</code></td>
</tr>
<tr>
<td></td>
<td><code>-prof-dir/usr/profiled a1.f90</code></td>
</tr>
<tr>
<td></td>
<td><code>a2.f90 a3.f90</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort -oa1 a1.o a2.o a3.o</code></td>
</tr>
<tr>
<td>Windows</td>
<td><code>ifort /Qprof-gen</code></td>
</tr>
<tr>
<td></td>
<td><code>/Qprof-dir:c:\profiled a1.f90 a2.f90 a3.f90</code></td>
</tr>
<tr>
<td></td>
<td><code>ifort a1.obj a2.obj a3.obj</code></td>
</tr>
</tbody>
</table>

   Use the `-prof-dir` (Linux and Mac OS X) or `/Qprof-dir` (Windows) option if the application includes the source files located in multiple directories; using the option insures the profile information is generated in one consistent place. The example commands demonstrate how to combine these options on multiple sources.

   The compiler gathers extra information when you use the `-prof-gen=srcpos` (Linux and Mac OS X) or `/Qprof-gen:srcpos` (Windows) option; however, the extra information is collected to provide support only for specific Intel tools, like the code-coverage tool. If you do not expect to use such tools, do not specify `-prof-gen=srcpos` (Linux and Mac OS X) or `/Qprof-gen:srcpos` (Windows); the extended option does not provide better optimization and could slow parallel compile times.

2. Instrumented execution
Run your instrumented program with a representative set of data to create one or more dynamic information files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and Mac OS X</td>
<td>./a1.out</td>
</tr>
<tr>
<td>Windows</td>
<td>a1.exe</td>
</tr>
</tbody>
</table>

Executing the instrumented applications generates dynamic information file that has a unique name and .dyn suffix. A new dynamic information file is created every time you execute the instrumented program.

You can run the program more than once with different input data.

3. Feedback compilation

Before this step, copy all .dyn and .dpi files into the same directory. Compile and link the source files with -prof-use (Linux and Mac OS X) or /Qprof-use (Windows); the option instructs the compiler to use the generated dynamic information to guide the optimization:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux and Mac OS X</td>
<td>ifort -prof-use -ipo</td>
</tr>
<tr>
<td></td>
<td>-prof-dir/usr/profiled a1.f90</td>
</tr>
<tr>
<td></td>
<td>a2.f90 a3.f90</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /Qprof-use /Qipo</td>
</tr>
<tr>
<td></td>
<td>/Qprof-dirc:\profiled a1.f90 a2.f90 a3.f90</td>
</tr>
</tbody>
</table>

This final phase compiles and links the sources files using the data from the dynamic information files generated during instrumented execution (phase 2).

In addition to the optimized executable, the compiler produces a pgopti.dpi file.

Most of the time, you should specify the default optimizations, -02 (Linux and Mac OS X) or /02 (Windows), for phase 1, and specify more advanced optimizations, -ipo (Linux) or /Qipo (Windows), during the final (phase 3) compilation. For example, the example shown above used -02 (Linux and Mac OS X) or /02 (Windows) in step 1 and -ipo (Linux or Mac OS X) or /Qipo (Windows) in step 3.

**NOTE.** The compiler ignores the -ipo or -ip (Linux and Mac OS X) or /Qipo or /Qip (Windows) option during phase 1 with -prof-gen (Linux and Mac OS X) or /Qprof-gen (Windows).
PGO Tools

PGO Tools Overview

This section describes the tools that take advantage or support the Profile-guided Optimizations (PGO) available in the compiler.

- code coverage tool
- test prioritization tool
- profmerge tool
- proforder tool

In addition to the tools, this section also contains information on using Software-based Speculative Precomputation, which will allow you to optimize applications using profiling- and sampling-feedback methods on IA-32 architectures.

code coverage Tool

The code coverage tool provides software developers with a view of how much application code is exercised when a specific workload is applied to the application. To determine which code is used, the code coverage tool uses Profile-guided Optimization (PGO) options and optimizations. The major features of the code coverage tool are:

- Visually presenting code coverage information for an application with a customizable code coverage coloring scheme
- Displaying dynamic execution counts of each basic block of the application
- Providing differential coverage, or comparison, profile data for two runs of an application

The information about using the code coverage tool is separated into the following sections:

- code coverage tool Requirements
- Visually Presenting Code Coverage for an Application
- Excluding Code from Coverage Analysis
- Exporting Coverage Data

The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate the in HTML-formatted report and export data in both text-, and XML-formatted files. The reports can be further customized to show color-coded, annotated, source-code listings that distinguish between used and unused code.
The code coverage tool is available on IA-32, Intel® 64, and IA-64 architectures on Linux* and Windows*. The tool is available on IA-32 and Intel® 64 architectures on Mac OS* X.

You can use the tool in a number of ways to improve development efficiency, reduce defects, and increase application performance:

- During the project testing phase, the tool can measure the overall quality of testing by showing how much code is actually tested.
- When applied to the profile of a performance workload, the code coverage tool can reveal how well the workload exercises the critical code in an application. High coverage of performance-critical modules is essential to taking full advantage of the Profile-Guided Optimizations that Intel Compilers offer.
- The tool provides an option, useful for both coverage and performance tuning, enabling developers to display the dynamic execution count for each basic block of the application.
- The code coverage tool can compare the profile of two different application runs. This feature can help locate portions of the code in an application that are unrevealed during testing but are exercised when the application is used outside the test space, for example, when used by a customer.

**code coverage tool Requirements**

To run the code coverage tool on an application, you must have following items:

- The application sources.
- The .spi file generated by the Intel® compiler when compiling the application for the instrumented binaries using the -prof-gen=srcpos (Linux and Mac OS X) or /Qprof-gen:srcpos (Windows) options.
- A pgopti.dpi file that contains the results of merging the dynamic profile information (.dyn) files, which is most easily generated by the profmerge tool. This file is also generated implicitly by the Intel® compilers when compiling an application with -prof-use (Linux and Mac OS X) or /Qprof-use (Windows) options with available .dyn and .dpi files.

See Understanding Profile-guided Optimization and Example of Profile-guided Optimization for general information on creating the files needed to run this tool.

**Using the Tool**

The tool uses the following syntax:

<table>
<thead>
<tr>
<th>Tool Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>codecov [-codecov_option]</td>
</tr>
</tbody>
</table>
where \texttt{-codecov\_option} is one or more optional parameters specifying the tool option passed to the tool. The available tool options are listed in code coverage tools Options (below). If you do not use any additional tool options, the tool will provide the top-level code coverage for the entire application.

In general, you must perform the following steps to use the code coverage tool:

1. Compile the application using \texttt{-prof-gen=srcpos} (Linux and Mac OS X) or \texttt{/Qprof-gen:srcpos} (Windows).

   This step generates an instrumented executable and a corresponding static profile information (pgopti.spi) file.

2. Run the instrumented application.

   This step creates the dynamic profile information (.dyn) file. Each time you run the instrumented application, the compiler generates a unique .dyn file either in the current directory or the directory specified in by prof\_dir.

3. Use the profmerge tool to merge all the .dyn files into one .dpi (pgopti.dpi) file.

   This step consolidates results from all runs and represents the total profile information for the application, generates an optimized binary, and creates the dpi file needed by the code coverage tool.

   You can use the profmerge tool to merge the .dyn files into a .dpi file without recompiling the application. The profmerge tool can also merge multiple .dpi files into one .dpi file using the profmerge \texttt{-a} option. Select the name of the output .dpi file using the profmerge \texttt{-prof\_dpi} option.

   \textbf{CAUTION.} The profmerge tool merges all .dyn files that exist in the given directory. Make sure unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code.

4. Run the code coverage tool. (The valid syntax and tool options are shown below.)

   This step creates a report or exported data as specified. If no other options are specified, the code coverage tool creates a single HTML file (CODE\_COVERAGE.HTML) and a sub-directory (CodeCoverage) in the current directory. Open the file in a web browser to view the reports.
NOTE. Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

The code coverage tool allows you to name the project and specify paths to specific, necessary files. The following example demonstrates how to name a project and specify .dpi and .spi files to use:

**Example: specify .dpi and .spi files**

```
codecov -prj myProject -spi pgopti.spi -dpi pgopti.dpi
```

The tool can add a contact name and generate an email link for that contact at the bottom of each HTML page. This provides a way to send an electronic message to the named contact. The following example demonstrates how to add specify a contact and the email links:

**Example: add contact information**

```
codecov -prj myProject -mname JoeSmith -maddr js@company.com
```

This following example demonstrates how to use the tool to specify the project name, specify the dynamic profile information file, and specify the output format and file name.

**Example: export data to text**

```
codecov -prj test1 -dpi test1.dpi -txtbcvrg test1_bcvrg.txt
```

code coverage tool Options

The tool uses the options listed in the table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-bcolor color</code></td>
<td>#FFFF99</td>
<td>Specifies the HTML color name for code in the uncovered blocks.</td>
</tr>
<tr>
<td><code>-beginblkdsbl string</code></td>
<td></td>
<td>Specifies the comment that marks the beginning of the code fragment to be ignored by the coverage tool.</td>
</tr>
<tr>

<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-ccolor color</td>
<td>#FFFFFF</td>
<td>Specifies the HTML color name or code of the covered code.</td>
</tr>
<tr>
<td>-comp file</td>
<td></td>
<td>Specifies the file name that contains the list of files being (or not)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>displayed.</td>
</tr>
<tr>
<td>-counts</td>
<td></td>
<td>Generates dynamic execution counts.</td>
</tr>
<tr>
<td>-demang</td>
<td></td>
<td>Demangles both function names and their arguments.</td>
</tr>
<tr>
<td>-dpi file</td>
<td>pgopti.dpi</td>
<td>Specifies the file name of the dynamic profile information file (.dpi).</td>
</tr>
<tr>
<td>-endblkdsbl string</td>
<td></td>
<td>Specifies the comment that marks the end of the code fragment to be</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ignored by the coverage tool.</td>
</tr>
<tr>
<td>-fcolor color</td>
<td>#FFCCCC</td>
<td>Specifies the HTML color name for code of the uncovered functions.</td>
</tr>
<tr>
<td>-help, -h</td>
<td></td>
<td>Prints tool option descriptions.</td>
</tr>
<tr>
<td>-icolor color</td>
<td>#FFFFFF</td>
<td>Specifies the HTML color name or code of the information lines, such as</td>
</tr>
<tr>
<td></td>
<td></td>
<td>basic-block markers and dynamic counts.</td>
</tr>
<tr>
<td>-maddr string</td>
<td>Nobody</td>
<td>Sets the email address of the web-page owner.</td>

<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-mname <em>string</em></td>
<td>Nobody</td>
<td>Sets the name of the web-page owner.</td>
</tr>
<tr>
<td>-nopartial</td>
<td></td>
<td>Treats partially covered code as fully covered code.</td>
</tr>
<tr>
<td>-nopmeter</td>
<td></td>
<td>Turns off the progress meter. The meter is enabled by default.</td>
</tr>
<tr>
<td>-onelinedsbl <em>string</em></td>
<td></td>
<td>Specifies the comment that marks individual lines of code or the whole functions to be ignored by the coverage tool.</td>
</tr>
<tr>
<td>-pcolor <em>color</em></td>
<td>#FAFAD2</td>
<td>Specifies the HTML color name or code of the partially covered code.</td>
</tr>
<tr>
<td>-prj <em>string</em></td>
<td></td>
<td>Sets the project name.</td>
</tr>
<tr>
<td>-ref</td>
<td></td>
<td>Finds the differential coverage with respect to ref_dpi_file.</td>
</tr>
<tr>
<td>-spi <em>file</em></td>
<td>pgopti.spi</td>
<td>Specifies the file name of the static profile information file (.spi).</td>
</tr>
<tr>
<td>-srcroot <em>dir</em></td>
<td></td>
<td>Specifies a different top level project directory than was used during compiler instrumentation run to use for relative paths to source files in place of absolute paths.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-txtbcvrg file</td>
<td></td>
<td>Export block-coverage for covered functions as text format. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-txtbcvrgfull file</td>
<td></td>
<td>Export block-coverage for entire application in text and HTML formats. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-txtdcg file</td>
<td></td>
<td>Generates the dynamic call-graph information in text format. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-txtfcvrg file</td>
<td></td>
<td>Export function coverage for covered function in text format. The file parameter must by in the form of a valid file name.</td>
</tr>
<tr>
<td>-ucolor color</td>
<td>#FFFFFF</td>
<td>Specifies the HTML color name or code of the unknown code.</td>
</tr>
<tr>
<td>-xcolor color</td>
<td>#90EE90</td>
<td>Specifies the HTML color of the code ignored.</td>
</tr>
<tr>
<td>-xmlbcvrg file</td>
<td></td>
<td>Export the block-coverage for the covered function in XML format. The file parameter must by in the form of a valid file name.</td>
</tr>
</tbody>
</table>
Visually Presenting Code Coverage for an Application

Based on the profile information collected from running the instrumented binaries when testing an application, the Intel® compiler will create HTML-formatted reports using the code coverage tool. These reports indicate portions of the source code that were or were not exercised by the tests. When applied to the profile of the performance workloads, the code coverage information shows how well the training workload covers the application's critical code. High coverage of performance-critical modules is essential to taking full advantage of the profile-guided optimizations.

The code coverage tool can create two levels of coverage:

- Top level (for a group of selected modules)
- Individual module source views

**Top Level Coverage**

The top-level coverage reports the overall code coverage of the modules that were selected. The following options are provided:

- Select the modules of interest
- For the selected modules, the tool generates a list with their coverage information. The information includes the total number of functions and blocks in a module and the portions that were covered.

---

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-xmlbcvrgfull file</td>
<td></td>
<td>Export function coverage for entire application in XML format in addition to HTML output. The file parameter must be in the form of a valid file name.</td>
</tr>
<tr>
<td>-xmlfcvrg file</td>
<td></td>
<td>Export function coverage for covered function in XML format. The file parameter must be in the form of a valid file name.</td>
</tr>
</tbody>
</table>
By clicking on the title of columns in the reported tables, the lists may be sorted in ascending or descending order based on:

- basic block coverage
- function coverage
- function name

By default, the code coverage tool generates a single HTML file (CODE_COVERAGE.HTML) and a subdirectory (CodeCoverage) in the current directory. The HTML file defines a frameset to display all of the other generated reports. Open the HTML file in a web-browser. The tool places all other generated report files in a CodeCoverage subdirectory.

If you choose to generate the html-formatted version of the report, you can view coverage source of that particular module directly from a browser. The following figure shows the top-level coverage report.
The coverage tool creates a frame set that allows quick browsing through the code to identify uncovered code. The top frame displays the list of uncovered functions while the bottom frame displays the list of covered functions. For uncovered functions, the total number of basic blocks of each function is also displayed. For covered functions, both the total number of blocks and the number of covered blocks as well as their ratio (that is, the coverage rate) are displayed.

For example, 66.67(4/6) indicates that four out of the six blocks of the corresponding function were covered. The block coverage rate of that function is thus 66.67%. These lists can be sorted based on the coverage rate, number of blocks, or function names. Function names are linked to the position in source view where the function body starts. So, just by one click, you can see the least-covered function in the list and by another click the browser displays the body of the function. You can scroll down in the source view and browse through the function body.

**Individual Module Source View**

Within the individual module source views, the tool provides the list of uncovered functions as well as the list of covered functions. The lists are reported in two distinct frames that provide easy navigation of the source code. The lists can be sorted based on:

- Number of blocks within uncovered functions
- Block coverage in the case of covered functions
- Function names

**Setting the Coloring Scheme for the Code Coverage**

The tool provides a visible coloring distinction of the following coverage categories: covered code, uncovered basic blocks, uncovered functions, partially covered code, and unknown code. The default colors that the tool uses for presenting the coverage information are shown in the tables that follows:

<table>
<thead>
<tr>
<th>Category</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Covered code</td>
<td>#FFFFFF</td>
<td>Indicates code was exercised by the tests. You can override the default color with the -ccolor tool option.</td>
</tr>
<tr>
<td>Uncovered basic block</td>
<td>#FFFF99</td>
<td>Indicates the basic blocks that were not exercised by any of the tests. However, these blocks were within functions that were executed</td>
</tr>
<tr>
<td>Category</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Uncovered function</td>
<td>#FFCCCC</td>
<td>Indicates functions that were never called during the tests. You can override the default color with the <code>-bcolor</code> tool option.</td>
</tr>
<tr>
<td>Partially covered code</td>
<td>#FAFAD2</td>
<td>Indicates that more than one basic block was generated for the code at this position. Some of the blocks were covered and some were not. You can override the default color with the <code>-pcolor</code> tool option.</td>
</tr>
<tr>
<td>Ignored code</td>
<td>#90EE90</td>
<td>Indicates code that was specifically marked to be ignored. You can override this default color using the <code>-xcolor</code> tool option.</td>
</tr>
<tr>
<td>Information lines</td>
<td>#FFFFFF</td>
<td>Indicates basic-block markers and dynamic counts. You can override the default color with the <code>-icolor</code> tool option.</td>
</tr>
<tr>
<td>Unknown</td>
<td>#FFFFFF</td>
<td>Indicates that no code was generated for this source line. Most probably, the source at this position is a comment, a header-file inclusion, or a variable declaration. You can override the default color with the <code>-ucolor</code> tool option.</td>
</tr>
</tbody>
</table>
The default colors can be customized to be any valid HTML color name or hexadecimal value using the options mentioned for each coverage category in the table above.

For code coverage colored presentation, the coverage tool uses the following heuristic: source characters are scanned until reaching a position in the source that is indicated by the profile information as the beginning of a basic block. If the profile information for that basic block indicates that a coverage category changes, then the tool changes the color corresponding to the coverage condition of that portion of the code, and the coverage tool inserts the appropriate color change in the HTML-formatted report files.

**NOTE.** You need to interpret the colors in the context of the code. For instance, comment lines that follow a basic block that was never executed would be colored in the same color as the uncovered blocks.

**Dynamic Counters**

The coverage tool can be configured to generate the information about the dynamic execution counts. This ability can display the dynamic execution count of each basic block of the application and is useful for both coverage and performance tuning.

The custom configuration requires using the `-counts` option. The counts information is displayed under the code after a "^" sign precisely under the source position where the corresponding basic block begins.

If more than one basic block is generated for the code at a source position (for example, for macros), then the total number of such blocks and the number of the blocks that were executed are also displayed in front of the execution count. For example, line 11 in the code is an `IF` statement:

```
11 IF ((N .EQ. 1).OR. (N .EQ. 0))
  ^ 10 (1/2)
12 PRINT N
  ^ 7
```

The coverage lines under code lines 11 and 12 contain the following information:

- The `IF` statement in line 11 was executed 10 times.
- Two basic blocks were generated for the `IF` statement in line 11.
Only one of the two blocks was executed, hence the partial coverage color.

Only seven out of the ten times variable n had a value of 0 or 1.

In certain situations, it may be desirable to consider all the blocks generated for a single source position as one entity. In such cases, it is necessary to assume that all blocks generated for one source position are covered when at least one of the blocks is covered. This assumption can be configured with the `-nopartial` option. When this option is specified, decision coverage is disabled, and the related statistics are adjusted accordingly. The code lines 11 and 12 indicate that the `print` statement in line 12 was covered. However, only one of the conditions in line 11 was ever true. With the `-nopartial` option, the tool treats the partially covered code (like the code on line 11) as covered.

**Differential Coverage**

Using the code coverage tool, you can compare the profiles from two runs of an application: a reference run and a new run identifying the code that is covered by the new run but not covered by the reference run. Use this feature to find the portion of the applications code that is not covered by the applications tests but is executed when the application is run by a customer. It can also be used to find the incremental coverage impact of newly added tests to an applications test space.

**Generating Reference Data**

Create the dynamic profile information for the reference data, which can be used in differential coverage reporting later, by using the `-ref` option. The following command demonstrate a typical command for generating the reference data:

```
Example: generating reference data

codecov -prj Project_Name -dpi customer.dpi -ref appTests.dpi
```

The coverage statistics of a differential-coverage run shows the percentage of the code exercised on a new run but missed in the reference run. In such cases, the tool shows only the modules that included the code that was not covered. Keep this in mind when viewing the coloring scheme in the source views.

The code that has the same coverage property (covered or not covered) on both runs is considered as covered code. Otherwise, if the new run indicates that the code was executed while in the reference run the code was not executed, then the code is treated as uncovered. On the other hand, if the code is covered in the reference run but not covered in the new run, the differential-coverage source view shows the code as covered.

**Running Differential Coverage**
To run the code coverage tool for differential coverage, you must have the application sources, the .spi file, and the .dpi file, as described in the code coverage tool Requirements section (above).

Once the required files are available, enter a command similar to the following begin the process of differential coverage analysis:

```
Example

codecov -prj Project_Name -spi pgopti.spi -dpi pgopti.dpi
```

Specify the .dpi and .spi files using the `-spi` and `-dpi` options.

**Excluding Code from Coverage Analysis**

The code coverage tool allows you to exclude portions of your code from coverage analysis. This ability can be useful during development; for example, certain portions of code might include functions used for debugging only. The test case should not include tests for functionality that will unavailable in the final application.

Another example of code that can be excluded is code that might be designed to deal with internal errors unlikely to occur in the application. In such cases, not having a test case lack of a test case is preferred. You might want to ignore infeasible (dead) code in the coverage analysis. The code coverage tool provides several options for marking portions of the code infeasible (dead) and ignoring the code at the file level, function level, line level, and arbitrary code boundaries indicated by user-specific comments. The following sections explain how to exclude code at different levels.

**Including and Excluding Coverage at the File Level**

The code coverage tool provides the ability to selectively include or exclude files for analysis. Create a component file and add the appropriate string values that indicate the file and directory name for code you want included or excluded. Pass the file name as a parameter of the `-comp` option. The following example shows the general command:

```
Example: specifying a component file

codecov -comp file
```

where `file` is the name of a text file containing strings that ask as file and directory name masks for including and excluding file-level analysis. For example, assume that the following:

- You want to include all files with the string "source" in the file name or directory name.
You create a component text file named `myComp.txt` with the selective inclusion string.

Once you have a component file, enter a command similar to the following:

### Example

```
codecov -comp myComp.txt
```

In this example, individual files name including the string "source" (like `source1.f` and `source2.f`) and files in directories where the name contains the string "source" (like `source/file1.f` and `source2/file2.f`) are included in the analysis.

Excluding files is done in the same way; however, the string must have a tilde (~) prefix. The inclusion and exclusion can be specified in the same component file.

For example, assume you want to analyze all individual files or files contained in a directory where the name included the string "source", and you wanted to exclude all individual file and files contained in directories where the name included the string "skip". You would add content similar to the following to the component file (`myComp.txt`) and pass it to the `-comp` option:

### Example: inclusion and exclusion strings

```
source
~skip
```

Entering the `codecov -comp myComp.txt` command with both instructions in the component file will instruct the tool to include individual files where the name contains "source" (like `source1.f` and `source2.f`) and directories where the name contains "source" (like `source/file1.f` and `source2/file2.f`), and exclude any individual files where the name contains "skip" (like `skipthis1.f` and `skipthis2.f`) or directories where the name contains "skip" (like `skipthese1\debug1.f` and `skipthese2\debug2.f`).

**Excluding Coverage at the Line and Function Level**

You can mark individual lines for exclusion my passing string values to the `-onelinedsbl` option. For example, assume that you have some code similar to the following:

### Sample code

```
print*, "ERROR: n = ", n  ! NO_COVER
print*, n2 = ", n2  ! INF IA-32 architecture
```
If you wanted to exclude all functions marked with the comments NO_COVER or INF IA-32 architecture, you would enter a command similar to the following.

**Example**

```
codecov -onelinedsbl NO_COVER -onelinedsbl "INF IA-32 architecture"
```

You can specify multiple exclusion strings simultaneously, and you can specify any string values for the markers; however, you must remember the following guidelines when using this option:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

An entire function can be excluded from coverage analysis using the same methods. For example, the following function will be ignored from the coverage analysis when you issue example command shown above.

**Sample code**

```fortran
subroutine dumpInfo (n)
  integer n ! NO_COVER
  ...
end subroutine
```

Additionally, you can use the code coverage tool to color the infeasible code with any valid HTML color code by combining the `-onelinedsbl` and `-xcolor` options. The following example commands demonstrate the combination:

**Example: combining tool options**

```
codecov -onelinedsbl INF -xcolor lightgreen
codecov -onelinedsbl INF -xcolor #CCFFCC
```

**Excluding Code by Defining Arbitrary Boundaries**

The code coverage tool provides the ability to arbitrarily exclude code from coverage analysis. This feature is most useful where the excluded code either occur inside of a function or spans several functions.
Use the \texttt{-beginblkdsbl} and \texttt{-endblkdsbl} options to mark the beginning and end, respectively, of any arbitrarily defined boundary to exclude code from analysis. Remember the following guidelines when using these options:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

For example assume that you have the following code:

```fortran
integer n, n2
n = 123
n2 = n*n
if (n2 .lt. 0) then
  ! /* BINF */
  print*, "ERROR: n = ", n
  print*, " n2 = ", n2
  ! // EINF
else if (n2 .eq. 0) then
  print*, "zero: n = ", n, " n2 = ", n2
else
  print*, "positive: n = ", n, " n2 = ", n2
endif
end
```

The following example commands demonstrate how to use the \texttt{-beginblkdsbl} option to mark the beginning and the \texttt{-endblkdsbl} option to mark the end of code to exclude from the sample shown above.

```bash
codecov -xcolor #ccFFCC -beginblkdsbl BINF -endblkdsbl EINF
codecov -xcolor #ccFFCC -beginblkdsbl "BEGIN_INF" -endblkdsbl "END_INF"
```
Notice that you can combine these options in combination with the `-xcolor` option.

**Exporting Coverage Data**

The code coverage tool provides specific options to extract coverage data from the dynamic profile information (.dpi files) that result from running instrumented application binaries under various workloads. The tool can export the coverage data in various formats for post-processing and direct loading into databases: the default HTML, text, and XML. You can choose to export data at the function and basic block levels.

There are two basic methods for exporting the data: quick export and combined export. Each method has associated options supported by the tool:

- **Quick export:** The first method is to export the data coverage to text- or XML-formatted files without generating the default HTML report. The application sources need not be present for this method. The code coverage tool creates reports and provides statistics only about the portions of the application executed. The resulting analysis and reporting occurs quickly, which makes it practical to apply the coverage tool to the dynamic profile information (the .dpi file) for every test case in a given test space instead of applying the tool to the profile of individual test suites or the merge of all test suites. The `-xmlfcvrg`, `-txtfcvrg`, `-xmlbcvrg` and `-txbrtcvrg` options support the first method.

- **Combined export:** The second method is to generate the default HTML and simultaneously export the data to text- and XML-formatted files. This process is slower than first method since the application sources are parsed and reports generated. The `-xmlbcvrgfull` and `-txbrtcvrgfull` options support the second method.

These export methods provide the means to quickly extend the code coverage reporting capabilities by supplying consistently formatted output from the code coverage tool. You can extend these by creating additional reporting tools on top of these report files.

**Quick Export**

The profile of covered functions of an application can be exported quickly using the `-xmlfcvrg`, `-txtfcvrg`, `-xmlbcvrg`, and `-txbrtcvrg` options. When using any of these options, specify the output file that will contain the coverage report. For example, enter a command similar to the following to generate a report of covered functions in XML formatted output:

```
Example: quick export of function data

codecov -prj test1 -dpi test1.dpi -xmlfcvrg test1_fcvrg.xml
```
The resulting report will show how many times each function was executed and the total number of blocks of each function together with the number of covered blocks and the block coverage of each function. The following example shows some of the content of a typical XML report.

**XML-formatted report example**

```xml
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.F">
    <FUNCTION name="f0" freq="2">
      <BLOCKS total="6" covered="5" coverage="83.33%"></BLOCKS>
    </FUNCTION>
    ...
  </MODULE>
  <MODULE name = "D:\SAMPLE2.F">
    ...
  </MODULE>
</PROJECT>
```

In the above example, we note that function f0, which is defined in file sample.f, has been executed twice. It has a total number of six basic blocks, five of which are executed, resulting in an 83.33% basic block coverage.

You can also export the data in text format using the `-txtfcvrg` option. The generated text report, using this option, for the above example would be similar to the following example:

**Text-formatted report example**

```
Covered Functions in File: "D:\SAMPLE.F"
"f0"  2  6  5  83.33
"f1"  1  6  4  66.67
"f2"  1  6  3  50.00
...
```

In the text formatted version of the report, the each line of the report should be read in the following manner:
<table>
<thead>
<tr>
<th>Column 1</th>
<th>Column 2</th>
<th>Column 3</th>
<th>Column 4</th>
<th>Column 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>function name</td>
<td>execution frequency</td>
<td>line number of the start of the function definition</td>
<td>column number of the start of the function definition</td>
<td>percentage of basic-block coverage of the function</td>
</tr>
</tbody>
</table>

Additionally, the tool supports exporting the block level coverage data using the `-xmlbcvrg` option. For example, enter a command similar to the following to generate a report of covered blocks in XML formatted output:

**Example: quick export of block data to XML**

```bash
codecov -prj test1 -dpi test1.dpi -xmlbcvrg test1_bcvrg.xml
```

The example command shown above would generate XML-formatted results similar to the following:

**XML-formatted report example**

```xml
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.cF90">
    <FUNCTION name="f0" freq="2">
      ...
      <BLOCK line="11" col="2">
        <INSTANCE id="1" freq="1" />
      </BLOCK>
      <BLOCK line="12" col="3">
        <INSTANCE id="1" freq="2" />
        <INSTANCE id="2" freq="1" />
      </BLOCK>
    </FUNCTION>
  </MODULE>
</PROJECT>
```

In the sample report, notice that one basic block is generated for the code in function f0 at the line 11, column 2 of the file sample.f90. This particular block has been executed only once. Also notice that there are two basic blocks generated for the code that starts at line 12, column...
3 of file. One of these blocks, which has id = 1, has been executed two times, while the other block has been executed only once. A similar report in text format can be generated through the `-txtbcvrg` option.

**Combined Exports**

The code coverage tool has also the capability of exporting coverage data in the default HTML format while simultaneously generating the text- and XML-formatted reports.

Use the `-xmlbcvrgfull` and `-txtbcvrgfull` options to generate reports in all supported formatted in a single run. These options export the basic-block level coverage data while simultaneously generating the HTML reports. These options generate more complete reports since they include analysis on functions that were not executed at all. However, exporting the coverage data using these options requires access to application source files and take much longer to run.

**Dynamic Call Graphs**

Using the `-txtdcg` option the tool can provide detailed information about the dynamic call graphs in an application. Specify an output file for the dynamic call-graph report. The resulting call graph report contains information about the percentage of static and dynamic calls (direct, indirect, and virtual) at the application, module, and function levels.

**test prioritization Tool**

The test prioritization tool enables the profile-guided optimizations on IA-32, Intel® 64, and IA-64 architectures, on Linux* and Windows*, to select and prioritize test for an application based on prior execution profiles. The tool is available on IA-32 and Intel® 64 architectures on Mac OS* X.

The tool offers a potential of significant time saving in testing and developing large-scale applications where testing is the major bottleneck.

Development often requires changing applications modules. As applications change, developers can have a difficult time retaining the quality of their functional and performance tests so they are current and on-target. The test prioritization tool lets software developers select and prioritize application tests as application profiles change.

The information about the tool is separated into the following sections:

- **Features and benefits**
- **Requirements and syntax**
- **Usage model**
- **Tool options**
- **Running the tool**
Features and Benefits

The test prioritization tool provides an effective testing hierarchy based on the code coverage for an application. The following list summarizes the advantages of using the tool:

- Minimizing the number of tests that are required to achieve a given overall coverage for any subset of the application: the tool defines the smallest subset of the application tests that achieve exactly the same code coverage as the entire set of tests.
- Reducing the turn-around time of testing: instead of spending a long time on finding a possibly large number of failures, the tool enables the users to quickly find a small number of tests that expose the defects associated with the regressions caused by a change set.
- Selecting and prioritizing the tests to achieve certain level of code coverage in a minimal time based on the data of the tests’ execution time.

See Understanding Profile-guided Optimization and Example of Profile-guided Optimization for general information on creating the files needed to run this tool.

test prioritization Tool Requirements

The test prioritization tool needs the following items to work:

- The .spi file generated by Intel® compilers when compiling the application for the instrumented binaries with the -prof-gen=srcpos (Linux* and Mac OS* X) or /Qprof-gen:srcpos (Windows*) option.
- The .dpi files generated by the profmerge tool as a result of merging the dynamic profile information .dyn files of each of the application tests. (Run the profmerge tool on all .dyn files that are generated for each individual test and name the resulting .dpi in a fashion that uniquely identifies the test.)

CAUTION. The profmerge tool merges all .dyn files that exist in the given directory. Make sure unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code;

- User-generated file containing the list of tests to be prioritized. For successful instrumented code run, you should:
- Name each test .dpi file so the file names uniquely identify each test.
Create a .dpi list file, which is a text file that contains the names of all .dpi test files.

Each line of the .dpi list file should include one, and only one .dpi file name. The name can optionally be followed by the duration of the execution time for a corresponding test in the dd:hh:mm:ss format.

For example: `Test1.dpi 00:00:60:35` states that Test1 lasted 0 days, 0 hours, 60 minutes and 35 seconds.

The execution time is optional. However, if it is not provided, then the tool will not prioritize the test for minimizing execution time. It will prioritize to minimize the number of tests only.

The tool uses the following general syntax:

```
Tool Syntax

tselect -dpi_list file
```

-`dpi_list` is a required tool option that sets the path to the list file containing the list of the all .dpi files. All other tool commands are optional.

**NOTE.** Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

**Usage Model**

The following figure illustrates a typical test prioritization tool usage model.

**test prioritization tool Options**

The tool uses the options that are listed in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-help</td>
<td></td>
<td>Prints tool option descriptions.</td>
</tr>
<tr>
<td>-dpi_list file</td>
<td></td>
<td>Required. Specifies the file name of the file that contains the names of the dynamic</td>
</tr>
</tbody>
</table>
profile information (.dpi) files. Each line of the file must contain only one .dpi file name, which can be optionally followed by its execution time. The name must uniquely identify the test.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-spi file</td>
<td>pgopti.spi</td>
<td>Specifies the file name of the static profile information file (.SPI).</td>
</tr>
<tr>
<td>-o file</td>
<td></td>
<td>Specifies the file name of the output report file.</td>
</tr>
<tr>
<td>-comp file</td>
<td></td>
<td>Specifies the file name that contains the list of files of interest.</td>
</tr>
<tr>
<td>-cutoff file</td>
<td></td>
<td>Instructs the tool to terminate when the cumulative block coverage reaches a preset percentage, as specified by value, of pre-computed total coverage. value must be greater than 0.0 (for example, 99.00) but not greater than 100. value can be set to 100.</td>
</tr>
<tr>
<td>-nototal</td>
<td></td>
<td>Instructs the tool to ignore the pre-compute total coverage process.</td>
</tr>
<tr>
<td>-mintime</td>
<td></td>
<td>Instructs the tool to minimize testing execution time. The execution time of each test must be provided on the</td>
</tr>
</tbody>
</table>
Running the tool

The following steps demonstrate one simple example for running the tool on IA-32 architectures.

1. Specify the directory by entering a command similar to the following:

   **Example**
   ```
   set prof-dir=c:\myApp\prof-dir
   ```

2. Compile the program and generate instrumented binary by issuing commands similar to the following:

   **Operating System** | **Command**
   --- | ---
   Linux and Mac OS X | `ifort -prof-gen=srcpos MyApp.f90`
   Windows | `ifort /Oprof-gen:srcpos MyApp.f90`

This commands shown above compiles the program and generates instrumented binary `myApp` as well as the corresponding static profile information `pgopti.spi`.

---

Option | Default | Description
--- | --- | ---
| -dpi_list | same line of dpi_list file, after the test name in dd:hh:mm:ss format. | Specifies a different top level project directory than was used during compiler instrumentation run with the prof-src-root compiler option to support relative paths to source files in place of absolute paths. | -verbose | Instructs the tool to generate more logging information about program progress. |
3. Make sure that unrelated .dyn files are not present by issuing a command similar to the following:

**Example**

```bash
rm prof-dir \*.dyn
```

4. Run the instrumented files by issuing a command similar to the following:

**Example**

```bash
myApp < data1
```

The command runs the instrumented application and generates one or more new dynamic profile information files that have an extension .dyn in the directory specified by the `-prof-dir` step above.

5. Merge all .dyn file into a single file by issuing a command similar to the following:

**Example**

```bash
profmerge -prof_dpi Test1.dpi
```

The `profmerge` tool merges all the .dyn files into one file (`Test1.dpi`) that represents the total profile information of the application on Test1.

6. Again make sure there are no unrelated .dyn files present a second time by issuing a command similar to the following:

**Example**

```bash
rm prof-dir \*.dyn
```

7. Run the instrumented application and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified the `prof-dir` step above by issuing a command similar to the following:

**Example**

```bash
myApp < data2
```

8. Merge all .dyn files into a single file, by issuing a command similar to the following
Example

```bash
profmerge -prof_dpi Test2.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (Test2.dpi) that represents the total profile information of the application on Test2.

9. Make sure that there are no unrelated .dyn files present for the final time, by issuing a command similar to the following:

```
Example
rm prof-dir \*.dyn
```

10. Run the instrumented application and generates one or more new dynamic profile information files that have an extension .dyn in the directory specified by `-prof-dir` by issuing a command similar to the following:

```
Example
myApp < data3
```

11. Merge all .dyn file into a single file, by issuing a command similar to the following:

```
Example
profmerge -prof_dpi Test3.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (Test3.dpi) that represents the total profile information of the application on Test3.

12. Create a file named `tests_list` with three lines. The first line contains `Test1.dpi`, the second line contains `Test2.dpi`, and the third line contains `Test3.dpi`.

**Tool Usage Examples**

When these items are available, the test prioritization tool may be launched from the command line in `prof-dir` directory as described in the following examples.

**Example 1: Minimizing the Number of Tests**

The following example describes how minimize the number of test runs.
Example Syntax

tselect -dpi_list tests_list -spi pgopti.spi

where the -spi option specifies the path to the .spi file.

The following sample output shows typical results.

Sample Output

<table>
<thead>
<tr>
<th>Total number of tests</th>
<th>= 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total block coverage</td>
<td>~ 52.17</td>
</tr>
<tr>
<td>Total function coverage</td>
<td>~ 50.00</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>num</th>
<th>%RatCvrg</th>
<th>%BlkCvrg</th>
<th>%FncCvrg</th>
<th>Test Name @ Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>87.50</td>
<td>45.65</td>
<td>37.50</td>
<td>Test3.dpi</td>
</tr>
<tr>
<td>2</td>
<td>100.50</td>
<td>52.17</td>
<td>50.00</td>
<td>Test2.dpi</td>
</tr>
</tbody>
</table>

In this example, the results provide the following information:

- By running all three tests, we achieve 52.17% block coverage and 50.00% function coverage.
- Test3 by itself covers 45.65% of the basic blocks of the application, which is 87.50% of the total block coverage that can be achieved from all three tests.
- By adding Test2, we achieve a cumulative block coverage of 52.17% or 100% of the total block coverage of Test1, Test2, and Test3.
- Elimination of Test1 has no negative impact on the total block coverage.

Example 2: Minimizing Execution Time

Suppose we have the following execution time of each test in the tests_list file:

<table>
<thead>
<tr>
<th>Sample Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test1.dpi 00:00:60:35</td>
</tr>
<tr>
<td>Test2.dpi 00:00:10:15</td>
</tr>
<tr>
<td>Test3.dpi 00:00:30:45</td>
</tr>
</tbody>
</table>
The following command minimizes the execution time by passing the `-mintime` option:

**Sample Syntax**

```
 tselect -dpi_list tests_list -spi pgopti.spi -mintime
```

The following sample output shows possible results:

**Sample Output**

```
<table>
<thead>
<tr>
<th>num</th>
<th>elapsedTime</th>
<th>%RatCvrg</th>
<th>%BlkCvrg</th>
<th>%FncCvrg</th>
<th>Test Name @ Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10:15</td>
<td>75.00</td>
<td>39.13</td>
<td>25.00</td>
<td>Test2.dpi</td>
</tr>
<tr>
<td>2</td>
<td>41:00</td>
<td>100.00</td>
<td>52.17</td>
<td>50.00</td>
<td>Test3.dpi</td>
</tr>
</tbody>
</table>
```

In this case, the results indicate that the running all tests sequentially would require one hour, 45 minutes, and 35 seconds, while the selected tests would achieve the same total block coverage in only 41 minutes.

The order of tests is based on minimizing time (first Test2, then Test3) could be different than when prioritization is done based on minimizing the number of tests. See Example 1 shown above: first Test3, then Test2. In Example 2, Test2 is the test that gives the highest coverage per execution time, so Test2 is picked as the first test to run.

**Using Other Options**

The `-cutoff` option enables the tool to exit when it reaches a given level of basic block coverage. The following example demonstrates how to the option:

**Example**

```
 tselect -dpi_list tests_list -spi pgopti.spi -cutoff 85.00
```
If the tool is run with the cutoff value of 85.00, as in the above example, only Test3 will be selected, as it achieves 45.65% block coverage, which corresponds to 87.50% of the total block coverage that is reached from all three tests.

The tool does an initial merging of all the profile information to figure out the total coverage that is obtained by running all the tests. The `-nototal` option enables you to skip this step. In such a case, only the absolute coverage information will be reported, as the overall coverage remains unknown.

**profmerge and proforder Tools**

**profmerge Tool**

Use the profmerge tool to merge dynamic profile information (.dyn) files and any specified summary files (.dpi). The compiler executes profmerge automatically during the feedback compilation phase when you specify `-prof-use` (Linux* and Mac OS* X) or `/Qprof-use` (Windows*).

The command-line usage for profmerge is as follows:

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>profmerge [-prof_dir dir_name]</td>
</tr>
</tbody>
</table>

The tool merges all .dyn files in the current directory, or the directory specified by `-prof_dir`, and produces a summary file: `pgopti.dpi`.

**NOTE.** The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example `-prof_dir`) instead of the hyphen used by compiler options (for example `-prof-dir` or `/Qprof-dir`) to join words. Also, on Windows* OS systems, the tool options are preceded by a hyphen (`"-"`) unlike Windows compiler options, which are preceded by a forward slash (`"/"`).

You can use profmerge tool to merge .dyn files into a .dpi file without recompiling the application. Thus, you can run the instrumented executable file on multiple systems to generate dyn files, and optionally use profmerge with the `-prof_dpi` option to name each summary dpi file created from the multiple dyn files.
Since the profmerge tool merges all the .dyn files that exist in the given directory, make sure unrelated .dyn files are not present; otherwise, profile information will be based on invalid profile data, which can negatively impact the performance of optimized code.

**profmerge Options**

The profmerge tool supports the following options:

<table>
<thead>
<tr>
<th>Tool Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-help</td>
<td>Lists supported options.</td>
</tr>
<tr>
<td>-nologo</td>
<td>Disables version information. This option is supported on Windows* only.</td>
</tr>
<tr>
<td>-exclude_funcs functions</td>
<td>Excludes functions from the profile. The list items must be separated by a comma (&quot;,&quot;); you can use a period (&quot;.&quot; ) as a wild card character in function names.</td>
</tr>
<tr>
<td>-prof_dir dir</td>
<td>Specifies the directory from which to read .dyn and .dpi files, and write the .dpi file. Alternatively, you can set the environment variable PROF_DIR.</td>
</tr>
<tr>
<td>-prof_dpi file</td>
<td>Specifies the name of the .dpi file being generated.</td>
</tr>
<tr>
<td>-dump</td>
<td>Displays profile information.</td>
</tr>
<tr>
<td>-src_old dir -src_new dir</td>
<td>Changes the directory path stored within the .dpi file.</td>
</tr>
<tr>
<td>-src_no_dir</td>
<td>Uses only the file name and not the directory name when reading dyn/dpi records. If you specify -src_no_dir, the directory name of the source file will be ignored when deciding</td>
</tr>
</tbody>
</table>
which profile data records correspond to a specific application routine, and the -src-root option is ignored.

-srcret-root dir

Specifies a directory path prefix for the root directory where the user’s application files are stored. This option is ignored if you specify -src_no_dir.

-a file1.dpi ... fileN.dpi

Specifies and merges available .dpi files.

-verbose

Instructs the tool to display full information during merge.

-weighted

Instructs the tool to apply an equal weighting (regardless of execution times) to the dyn file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally.

<table>
<thead>
<tr>
<th>Tool Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>which profile data records correspond to a specific application routine, and the -src-root option is ignored.</td>
</tr>
<tr>
<td>-srcret-root dir</td>
<td>Specifies a directory path prefix for the root directory where the user’s application files are stored. This option is ignored if you specify -src_no_dir.</td>
</tr>
<tr>
<td>-a file1.dpi ... fileN.dpi</td>
<td>Specifies and merges available .dpi files.</td>
</tr>
<tr>
<td>-verbose</td>
<td>Instructs the tool to display full information during merge.</td>
</tr>
<tr>
<td>-weighted</td>
<td>Instructs the tool to apply an equal weighting (regardless of execution times) to the dyn file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally.</td>
</tr>
</tbody>
</table>

**Relocating source files using profmerge**

The Intel® compiler uses the full path to the source file for each routine to look up the profile summary information associated with that routine. By default, this prevents you from:

- Using the profile summary file (.dpi) if you move your application sources.
- Sharing the profile summary file with another user who is building identical application sources that are located in a different directory.

You can disable the use of directory names when reading dyn/dpi file records by specifying the profmerge option -src_no_dir. This profmerge option is the same as the compiler option -no-prof-src-dir (Linux and Mac OS X) and /Qprof-src-dir- (Windows).

To enable the movement of application sources, as well as the sharing of profile summary files, you can use the profmerge option -src-root to specify a directory path prefix for the root directory where the application files are stored. Alternatively, you can specify the option pair -src_old -src_new to modify the data in an existing summary dpi file. For example:
Example: relocation command syntax

```
profmerge -prof_dir <dir1> -src_old <dir2> -src_new <dir3>
```

where `<dir1>` is the full path to dynamic information file (.dpi), `<dir2>` is the old full path to source files, and `<dir3>` is the new full path to source files. The example command (above) reads the `pgopti.dpi` file, in the location specified in `<dir1>`. For each routine represented in the `pgopti.dpi` file, whose source path begins with the `<dir2>` prefix, profmerge replaces that prefix with `<dir3>`. The `pgopti.dpi` file is updated with the new source path information.

You can run profmerge more than once on a given `pgopti.dpi` file. For example, you may need to do this if the source files are located in multiple directories:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Command Examples</th>
</tr>
</thead>
</table>
| Linux and Mac OS X   | `profmerge -prof_dir -src_old /src/prog_1 -src_new /src/prog_2`
|                      | `profmerge -prof_dir -src_old /proj_1 -src_new /proj_2`    |
| Windows              | `profmerge -src_old "c:/program files" -src_new "e:/program files"`
|                      | `profmerge -src_old c:/proj/application -src_new d:/app`   |

In the values specified for `-src_old` and `-src_new`, uppercase and lowercase characters are treated as identical. Likewise, forward slash (`/`) and backward slash (`\`) characters are treated as identical.

**NOTE.** Because the source relocation feature of profmerge modifies the `pgopti.dpi` file, consider making a backup copy of the file before performing the source relocation.

**proforder Tool**

The proforder tool is used as part of the feedback compilation phase, to improve program performance. Use proforder to generate a function order list for use with the `/ORDER` linker option. The tool uses the following syntax:
Syntax

proforder [-prof_dir dir] [-o file]

where dir is the directory containing the profile files (.dpi and .spi), and file is the optional name of the function order list file. The default name is proford.txt.

**NOTE.** The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example -prof_dir) instead of the hyphen used by compiler options (for example -prof-dir or /Qprof-dir) to join words. Also, on Windows* OS systems, the tool options are preceded by a hyphen ("-"), unlike Windows compiler options, which are preceded by a forward slash ("/").

**proforder Options**

The proforder tool supports the following options:

<table>
<thead>
<tr>
<th>Tool Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-help</td>
<td></td>
<td>Lists supported options.</td>
</tr>
<tr>
<td>-nologo</td>
<td></td>
<td>Disables version information. This option is supported on Windows* only.</td>
</tr>
<tr>
<td>-omit_static</td>
<td></td>
<td>Instructs the tool to omit static functions from function ordering.</td>
</tr>
<tr>
<td>-prof_dir dir</td>
<td></td>
<td>Specifies the directory where the .spi and .dpi file reside.</td>
</tr>
<tr>
<td>-prof_dpi file</td>
<td></td>
<td>Specifies the name of the .dpi file.</td>
</tr>
<tr>
<td>-prof_file string</td>
<td></td>
<td>Selects the .dpi and .spi files that include the substring value in the file name matching the values passed as string.</td>
</tr>
</tbody>
</table>
Using Function Order Lists, Function Grouping, Function Ordering, and Data Ordering Optimizations

Instead of doing a full multi-file interprocedural build of your application by using the compiler option `-ipo` (Linux* OS) or `/Qipo` (Windows* OS), you can obtain some of the benefits by having the compiler and linker work together to make global decisions about where to place the procedures and data in your application. These optimizations are not supported on Mac OS* X systems.

The following table lists each optimization, the type of procedures or global data it applies to, and the operating systems and architectures that it is supported on.

<table>
<thead>
<tr>
<th>Optimization</th>
<th>Type of Procedure or Data</th>
<th>Supported OS and Architectures</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Function Order Lists:</strong></td>
<td>EXTERNAL procedures and library procedures only (not other types of static procedures).</td>
<td>Windows OS: IA-32, Intel® 64, and IA-64 architectures</td>
</tr>
<tr>
<td>Specifies the order in which the linker should link the non-static routines (procedures) of your program. This optimization can improve application performance by improving code locality and reduce paging. Also see Comparison of Function Order Lists and IPO Code Layout.</td>
<td>Linux OS: not supported</td>
<td></td>
</tr>
<tr>
<td>Optimization</td>
<td>Type of Procedure or Data</td>
<td>Supported OS and Architectures</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------</td>
</tr>
<tr>
<td>Function Ordering:</td>

</tr>
<tr>
<td></td>
<td>profiling information. Specifies the order in which the linker should link global data</td>
<td></td>
</tr>
<tr>
<td></td>
<td>of your program. This optimization can improve application performance by improving the</td>
<td></td>
</tr>
<tr>
<td></td>
<td>locality of static global data, reduce paging of large data sets, and improve data cache</td>
<td></td>
</tr>
<tr>
<td></td>
<td>use.</td>
<td></td>
</tr>
</tbody>
</table>

You can use only one of the function-related ordering optimizations listed above. However, you can use the Data Ordering optimization with any one of the function-related ordering optimizations listed above, such as Data Ordering with Function Ordering, or Data Ordering with Function Grouping. In this case, specify the `prof-gen` option keyword `globdata` (needed for Data Ordering) instead of `srcpos` (needed for function-related ordering).
The following sections show the commands needed to implement each of these optimizations: function order list, function grouping, function ordering, and data ordering. For all of these optimizations, omit the -ipo (Linux OS) or /Qipo (Windows OS) or equivalent compiler option.

**Generating a Function Order List (Windows OS)**

This section provides an example of the process for generating a function order list. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90. Additionally, assume you have created a directory for the profile data files called c:\profdata. You would enter commands similar to the following to generate and use a function order list for your Windows application.

1. Compile your program using the /Qprof-gen:srcpos option. Use the /Qprof-dir option to specify the directory location of the profile files. This step creates an instrumented executable.

   **Example commands**
   
   ```
   ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90
   ```

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

   **Example commands**
   
   ```
   myprog.exe
   ```

3. Before this step, copy all .dyn and .dpi files into the same directory. Merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the pgopti.dpi file. Use the /prof_dir option to specify the directory location of the .dyn files.

   **Example commands**
   
   ```
   profmerge /prof_dir c:\profdata
   ```

4. Generate the function order list using the proforder tool. (By default, the function order list is produced in the file proford.txt.)
**Using Function Grouping (Linux OS)**

This section provides a general example of the process for using the function grouping optimization. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90. Additionally, assume you have created a directory for the profile data files called profdata. You would enter commands similar to the following to use a function grouping for your Linux application.

1. **Compile your program using the -prof-gen option. Use the -prof-dir option to specify the directory location of the profile files. This step creates an instrumented executable.**

   **Example commands**
   
   ```bash
   ifort -o myprog -prof-gen -prof-dir ./profdata file1.f90 file2.f90
   ```

2. **Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.**

   **Example commands**
   
   ```bash
   ./myprog
   ```

3. **Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the pgopti.dpi file.**
4. Compile the application with the generated profile feedback by specifying the -prof-func-group option to request the function grouping as well as the -prof-use option to request feedback compilation. Again, use the -prof-dir option to specify the location of the profile files.

Example commands

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>ifort /exe:myprog file1.f90 file2.f90 -prof-func-group -prof-use -prof-dir ./profdata</td>
</tr>
</tbody>
</table>

Using Function Ordering

This section provides an example of the process for using the function ordering optimization. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90. Additionally, assume you have created a directory for the profile data files called c:\profdata (on Windows) or ./profdata (on Linux). You would enter commands similar to the following to generate and use function ordering for your application.

1. Compile your program using the -prof-gen=srcpos (Linux) or /Qprof-gen:srcpos (Windows) option. Use the -prof-dir (Linux) or /Qprof-dir (Windows) option to specify the directory location of the profile files. This step creates an instrumented executable.

Example commands

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>ifort -o myprog -prof-gen=srcpos -prof-dir ./profdata file1.f90 file2.f90</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90</td>
</tr>
</tbody>
</table>

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

Example commands

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>./myprog</td>
</tr>
</tbody>
</table>
3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the pgopti.dpi file.

4. Compile the application with the generated profile feedback by specifying the -prof-func-order (Linux) or /Qprof-func-order (Windows) option to request the function ordering as well as the -prof-use (Linux) or /Qprof-use (Windows) option to request feedback compilation. Again, use the -prof-dir (Linux) or /Qprof-dir (Windows) option to specify the location of the profile files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>myprog.exe</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux</td>
<td>ifort -o myprog -prof-dir ./profdata file1.f90 file2.f90 -prof-func-order -prof-use</td>
</tr>
<tr>
<td>Windows</td>
<td>ifort /exe:myprog /Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-func-order /Qprof-use</td>
</tr>
</tbody>
</table>

**Using Data Ordering**

This section provides an example of the process for using the data order optimization. Assume you have a Fortran program that consists of the following files: file1.f90 and file2.f90. Additionally, assume you have created a directory for the profile data files called c:\profdata (on Windows) or ./profdata (on Linux). You would enter commands similar to the following to use data ordering for your application.

1. Compile your program using the -prof-gen=globdata (Linux) or /Qprof-gen=globdata (Windows) option. Use the -prof-dir (Linux) or /Qprof-dir (Windows) option to specify the directory location of the profile files. This step creates an instrumented executable.
<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Linux</strong></td>
<td><code>ifort -o myprog -prof-gen=globdata -prof-dir ./profdata file1.f90 file2.f90</code></td>
</tr>
<tr>
<td><strong>Windows</strong></td>
<td><code>ifort /exe:myprog /Qprof-gen=globdata /Qprof-dir c:\profdata file1.f90 file2.f90</code></td>
</tr>
</tbody>
</table>

2. Run the instrumented program with one or more sets of input data. If you specified a location other than the current directory, change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Linux</strong></td>
<td><code>./myprog</code></td>
</tr>
<tr>
<td><strong>Windows</strong></td>
<td><code>myprog.exe</code></td>
</tr>
</tbody>
</table>

3. Copy all `.dyn` and `.dpi` files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the `profmerge` tool to produce the `pgopti.dpi` file.

4. Compile the application with the generated profile feedback by specifying the `-prof-data-order` (Linux) or `/Qprof-data-order` option to request the data ordering as well as the `-prof-use` (Linux) or `/Qprof-use` (Windows) option to request feedback compilation. Again, use the `-prof-dir` (Linux) or `/Qprof-dir` (Windows) option to specify the location of the profile files.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Linux</strong></td>
<td><code>ifort -o myprog -prof-dir ./profdata file1.f90 file2.f90 -prof-data-order -prof-use</code></td>
</tr>
<tr>
<td><strong>Windows</strong></td>
<td><code>ifort /exe:myprog Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-data-order /Qprof-use</code></td>
</tr>
</tbody>
</table>
Comparison of Function Order Lists and IPO Code Layout

The Intel® compiler provides two methods of optimizing the layout of functions in the executable:

- Using a function order list
- Using the /Qipo (Windows) compiler option

Each method has its advantages. A function order list, created with proforder, lets you optimize the layout of non-static functions: that is, external and library functions whose names are exposed to the linker.

The compiler cannot affect the layout order for functions it does not compile, such as library functions. The function layout optimization is performed automatically when IPO is active.

**Function Order List Effects**

<table>
<thead>
<tr>
<th>Function Type</th>
<th>IPO Code Layout</th>
<th>Function Ordering with proforder</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static</td>
<td>X</td>
<td>No effect</td>
</tr>
<tr>
<td>Extern</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>Library</td>
<td>No effect</td>
<td>X</td>
</tr>
</tbody>
</table>

**Function Order List Usage Guidelines (Windows*)**

Use the following guidelines to create a function order list:

- The order list only affects the order of non-static functions.

**PGO API Support**

**API Support Overview**

The Profile Information Generation Support (Profile IGS) lets you control the generation of profile information during the instrumented execution phase of profile-guided optimizations.

A set of functions and an environment variable comprise the Profile IGS. The remaining topics in this section describe the associated functions and environment variables.
The compiler sets a define for _PGO_INSTRUMENT when you compile with either `-prof-gen` (Linux* and Mac OS* X) or `/Qprof-gen` (Windows*). Without instrumentation, the Profile IGS functions cannot provide PGO API support.

**NOTE.** The Profile IGS functions are written in C. Fortran applications must call C/C++ functions.

Normally, profile information is generated by an instrumented application when it terminates by calling the standard `exit()` function.

To ensure that profile information is generated, the functions described in this section may be necessary or useful in the following situations:

- The instrumented application exits using a non-standard exit routine.
- The instrumented application is a non-terminating application: `exit()` is never called.
- The application requires control of when the profile information is generated.

You can use the Profile IGS functions in your application by including a header file at the top of any source file where the functions may be used.

**Example**

```c
INCLUDE "pgouser.h"
```

**The Profile IGS Environment Variable**

The environment variable for Profile IGS is `INTEL_PROF_DUMP_INTERVAL`. This environment variable may be used to initiate Interval Profile Dumping in an instrumented user application.

**See Also**

- PGO API Support
- `_PGOPTI_Set_Interval_Prof_Dump()`

**PGO Environment Variables**

The environment variables determine the directory in which to store dynamic information files, control the creation of one or multiple dyn files to collect profiling information, and determine whether to overwrite `pgopti.dpi`.

The environment variables are described in the table below.
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>INTEL PROF DUMP_CUMULATIVE</strong></td>
<td>When using interval profile dumping (initiated by INTEL PROF DUMP INTERVAL or the function _PGOPTI_Set_Interval_Prof_Dump) during the execution of an instrumented user application, allows creation of a single .dyn file to contain profiling information instead of multiple .dyn files. If this environment variable is not set, executing an instrumented user application creates a new .dyn file for each interval. Setting this environment variable is useful for applications that do not terminate or those that terminate abnormally (bypass the normal exit code).</td>
</tr>
<tr>
<td><strong>INTEL PROF DUMP INTERVAL</strong></td>
<td>Initiates interval profile dumping in an instrumented user application. This environment variable may be used to initiate Interval Profile Dumping in an instrumented application. See Interval Profile Dumping for more information.</td>
</tr>
<tr>
<td><strong>PROF_DIR</strong></td>
<td>Specifies the directory in which dynamic information files are created. This variable applies to all three phases of the profiling process.</td>
</tr>
<tr>
<td><strong>PROF_DUMP_INTERVAL</strong></td>
<td>Deprecated. Please use INTEL PROF DUMP INTERVAL instead.</td>
</tr>
<tr>
<td><strong>PROF_NO_CLOBBER</strong></td>
<td>Alters the feedback compilation phase slightly. By default, during the feedback compilation phase, the compiler merges data from all dynamic information files and creates a new pgopti.dpi file if the .dyn files are newer than an existing pgopti.dpi file.</td>
</tr>
</tbody>
</table>
When this variable is set the compiler does not overwrite the existing `pgopti.dpi` file. Instead, the compiler issues a warning. You must remove the `pgopti.dpi` file if you want to use additional dynamic information files.

See the appropriate operating system documentation for instructions on how to specify environment variables and their values.

## Dumping Profile Information

The `_PGOPTI_Prof_Dump_All()` function dumps the profile information collected by the instrumented application. The prototype of the function call is listed below.

### Syntax

```c
void _PGOPTI_Prof_Dump_All(void);
```

An older version of this function, `_PGOPTI_Prof_Dump()`, which will also dump profile information is still available; the older function operates much like `_PGOPTI_Prof_Dump_All()`, except on Linux when used in connection with shared libraries (.so) and `_exit()` to terminate a program. When `_PGOPTI_Prof_Dump_All()` is called before `_exit()` to terminate the program, the new function insures that a `.dyn` file is created for all shared libraries needing to create a `.dyn` file. Use `_PGOPTI_Prof_Dump_All()` on Linux to insure portability and correct functionality.

The profile information is generated in a `.dyn` file (generated in phase 2 of PGO).
**Recommended usage**

Insert a single call to this function in the body of the function which terminates the user application. Normally, `_PGOPTI_Prof_Dump_All()` should be called just once. It is also possible to use this function in conjunction with `_PGOPTI_Prof_Reset()` function to generate multiple .dyn files (presumably from multiple sets of input data).

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| ! Selectively collect profile information  
! for the portion of the application  
! involved in processing input data.  
input_data = get_input_data()

**Dumping Profile Data**

This discussion provides an example of how to call the C PGO API routines from Fortran.

As part of the instrumented execution phase of PGO, the instrumented program writes profile data to the dynamic information file (.dyn file).

The profile information file is written after the instrumented program returns normally from `PROGRAM()` or calls the standard exit function.
Programs that do not terminate normally, can use the _PGOPTI_Prof_Dump_All function. During the instrumentation compilation, using the -prof-gen (Linux* and Mac OS* X) or /Qprof-gen (Windows*) option, you can add a call to this function to your program using a strategy similar to the one shown below:

**Example**

```fortran
interface
    subroutine PGOPTI_Prof_Dump_All()
        !DEC$attributes c,alias:'PGOPTI_Prof_Dump_All':PGOPTI_Prof_Dump_All
        end subroutine
    subroutine PGOPTI_Prof_Reset()
        !DEC$attributes c,alias:'PGOPTI_Prof_Reset':PGOPTI_Prof_Reset
        end subroutine
end interface

call PGOPTI_Prof_Dump_All()
```

**CAUTION.** You must remove the call or comment it out prior to the feedback compilation with -prof-use (Linux and Mac OS X) or /Qprof-use (Windows).

**Interval Profile Dumping**

The _PGOPTI_Set_Interval_Prof_Dump() function activates Interval Profile Dumping and sets the approximate frequency at which dumps occur. This function is used in non-terminating applications.

The prototype of the function call is listed below.

**Syntax**

```c
void _PGOPTI_Set_Interval_Prof_Dump(int interval);
```

This function is used in non-terminating applications.
The **interval** parameter specifies the time interval at which profile dumping occurs and is measured in milliseconds. For example, if interval is set to 5000, then a profile dump and reset will occur approximately every 5 seconds. The interval is approximate because the time-check controlling the dump and reset is only performed upon entry to any instrumented function in your application.

Setting the interval to zero or a negative number will disable interval profile dumping, and setting a very small value for the interval may cause the instrumented application to spend nearly all of its time dumping profile information. Be sure to set interval to a large enough value so that the application can perform actual work and substantial profile information is collected.

You can use the `profmerge` tool to merge the `.dyn` files.

**Recommended usage**

Call this function at the start of a non-terminating user application to initiate interval profile dumping. Note that an alternative method of initiating interval profile dumping is by setting the environment variable `INTEL_PROF_DUMP_INTERVAL` to the desired interval value prior to starting the application.

Using interval profile dumping, you should be able to profile a non-terminating application with minimal changes to the application source code.

**Resetting the Dynamic Profile Counters**

The `_PGOPTI_Prof_Reset()` function resets the dynamic profile counters. The prototype of the function call is listed below.

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>void _PGOPTI_Prof_Reset(void);</code></td>
</tr>
</tbody>
</table>

**Recommended usage**

Use this function to clear the profile counters prior to collecting profile information on a section of the instrumented application. See the example under Dumping Profile Information.

**Dumping and Resetting Profile Information**

The `_PGOPTI_Prof_Dump_And_Reset()` function dumps the profile information to a new `.dyn` file and then resets the dynamic profile counters. Then the execution of the instrumented application continues.

The prototype of the function call is listed below.
Syntax

```c
void _PGOPTI_Prof_Dump_And_Reset(void);
```

This function is used in non-terminating applications and may be called more than once. Each call will dump the profile information to a new .dyn file.

**Recommended usage**

Periodic calls to this function enables a non-terminating application to generate one or more profile information files (.dyn files). These files are merged during the feedback phase (phase 3) of profile-guided optimizations. The direct use of this function enables your application to control precisely when the profile information is generated.
High-Level Optimizations (HLO) Overview

HLO exploits the properties of source code constructs (for example, loops and arrays) in applications developed in high-level programming languages. Within HLO, loop transformation techniques include:

- Loop Permutation or Interchange
- Loop Distribution
- Loop Fusion
- Loop Unrolling
- Data Prefetching
- Scalar Replacement
- Unroll and Jam
- Loop Blocking or Tiling
- Partial-Sum Optimization
- Loadpair Optimization
- Predicate Optimization
- Loop Versioning with Runtime Data-Dependence Check (IA-64 architecture only)
- Loop Versioning with Low Trip-Count Check
- Loop Reversal
- Profile-Guided Loop Unrolling
- Loop Peeling
- Data Transformation: Malloc Combining and Memset Combining
- Loop Rerolling
- Memset and Memcpy Recognition
- Statement Sinking for Creating Perfect Loopnests

While the default optimization level, `-O2` (Linux* OS and Mac OS* X) or `/O2` (Windows* OS) option, performs some high-level optimizations (for example, prefetching, complete unrolling, etc.), specifying `-O3` (Linux and Mac OS X) or `/O3` (Windows) provides the best chance for performing loop transformations to optimize memory accesses; the scope of optimizations enabled by these options is different for IA-32 architecture, Intel® 64, and IA-64 architectures.
Applications for the IA-32 and Intel® 64 architectures

In conjunction with the vectorization options, -ax and -x (Linux and Mac OS X) or /Qax and /Qx (Windows), the -03 (Linux and Mac OS X) or /O3 (Windows) option causes the compiler to perform more aggressive data dependency analysis than the default -02 (Linux and Mac OS X) or /O2 (Windows).

Compiler prefetching is disabled in favor of the prefetching support available in the processors.

Applications for the IA-32 and IA-64 architectures

The -03 (Linux and Mac OS X) or /O3 (Windows) option enables the -02 (Linux and Mac OS X) or /O2 (Windows) option and adds more aggressive optimizations (like loop transformations); 03 optimizes for maximum speed, but may not improve performance for some programs.

Applications for the IA-64 architecture

The -ivdep-parallel (Linux) or /Qivdep-parallel (Windows) option implies there is no loop-carried dependency in the loop where an IVDEP directive is specified. (This strategy is useful for sparse matrix applications.)

Tune applications for IA-64 architecture by following these general steps:

1. Compile your program with -03 (Linux) or /O3 (Windows) and -ipo (Linux) or /Qipo (Windows). Use profile guided optimization whenever possible.
2. Identify hot spots in your code.
3. Generate a high-level optimization report.
4. Check why loops are not software pipelined.
5. Make the changes indicated by the results of the previous steps.
6. Repeat these steps until you achieve the desired performance.

General Application Tuning

In general, you can use the following strategies to tune applications for multiple architectures:

- Use !DEC$ ivdep to tell the compiler there is no dependency. You may also need the -ivdep-parallel (Linux and Mac OS X) or /Qivdep-parallel (Windows) option to indicate there is no loop carried dependency.
• Use !DEC$ swp to enable software pipelining (useful for lop-sided control and unknown loop count).

• Use !DEC$ loop count(n) when needed.

• If cray pointers are used, use -safe-cray-ptr (Linux and Mac OS X) or /Qsafe-cray-ptr (Windows) to indicate there is no aliasing.

• Use !DEC$ distribute point to split large loops (normally, this is automatically done).

• Check that the prefetch distance is correct. Use CDEC$ prefetch to override the distance when it is needed.

### Loop Unrolling

The benefits of loop unrolling are as follows:

- Unrolling eliminates branches and some of the code.
- Unrolling enables you to aggressively schedule (or pipeline) the loop to hide latencies if you have enough free registers to keep variables live.
- For processors based on the IA-32 architectures, the processor can correctly predict the exit branch for an inner loop that has 16 or fewer iterations, if that number of iterations is predictable and there are no conditional branches in the loop. Therefore, if the loop body size is not excessive, and the probable number of iterations is known, unroll inner loops for the processors, until they have a maximum of 16 iterations.
- A potential limitation is that excessive unrolling, or unrolling of very large loops, can lead to increased code size.

The -unroll[n] (Linux* and Mac OS* X) or /Qunroll:[n] (Windows*) option controls how the Intel® compiler handles loop unrolling.

Refer to Applying Optimization Strategies for more information.

<table>
<thead>
<tr>
<th>Linux and Mac OS X</th>
<th>Windows</th>
<th>Description</th>
</tr>
</thead>
</table>
| -unrolln           | /Qunroll:n | Specifies the maximum number of times you want to unroll a loop. The following examples unrolls a loop four times:  
ifort -unroll4 a.f90  
(Linux and Mac OS X) |
<table>
<thead>
<tr>
<th>Linux and Mac OS X</th>
<th>Windows</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>ifort /Qunroll:4 a.f90 (Windows)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(Linux and Mac OS X)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(Windows)</td>
</tr>
</tbody>
</table>

**NOTE.** The compilers for IA-64 architecture recognize only $n = 0$; any other value is ignored.

Omitting a value for $n$ lets the compiler decide whether to perform unrolling or not. This is the default; the compiler uses default heuristics or defines $n$.

Passing 0 as $n$ disables loop unrolling; the following examples disables loop unrolling:

ifort -unroll0 a.f90 (Linux and Mac OS X)  
ifort /Qunroll:0 a.f90 (Windows)  
ifort /Qunroll:0 a.f90 (Linux and Mac OS X)  
ifort /Qunroll:0 a.f90 (Windows)

---

**Loop Independence**

Loop independence is important since loops that are independent can be parallelized. Independent loops can be parallelized in a number of ways, from the course-grained parallelism of OpenMP*, to fine-grained Instruction Level Parallelism (ILP) of vectorization and software pipelining.
Loops are considered independent when the computation of iteration Y of a loop can be done independently of the computation of iteration X. In other words, if iteration 1 of a loop can be computed and iteration 2 simultaneously could be computed without using any result from iteration 1, then the loops are independent.

Occasionally, you can determine if a loop is independent by comparing results from the output of the loop with results from the same loop written with a decrementing index counter.

For example, the loop shown in example 1 might be independent if the code in example 2 generates the same result.

```
Example

subroutine loop_independent_A (a,b,MAX)
  implicit none
  integer :: j, MAX, a(MAX), b(MAX)
  do j=0, MAX
    a(j) = b(j)
  end do
end subroutine loop_independent_A

subroutine loop_independent_B (a,b,MAX)
  implicit none
  integer :: j, MAX, a(MAX), b(MAX)
  do j=MAX, 0, -1
    a(j) = b(j)
  end do
end subroutine loop_independent_B
```

When loops are dependent, improving loop performance becomes much more difficult. Loops can be dependent in several, general ways.

- **Flow Dependency**
- **Anti Dependency**
- **Output Dependency**
- **Reductions**

The following sections illustrate the different loop dependencies.
Flow Dependency - Read After Write

Cross-iteration flow dependence is created when variables are written then read in different iterations, as shown in the following example:

Example

```fortran
subroutine flow_dependence (A,MAX)
  implicit none
  integer :: J,MAX
  real :: A(MAX)
  do j=1, MAX
    A(J)=A(J-1)
  end do
end subroutine flow_dependence
```

The above example is equivalent to the following lines for the first few iterations:

Sample Iterations

```fortran
```

Recurrence relations feed information forward from one iteration to the next.

Example

```fortran
subroutine time_stepping_loops (a,b,MAX)
  implicit none
  integer :: J,MAX
  real :: a(MAX), b(MAX)
  do j=1, MAX
    a(j) = a(j-1) + b(j)
  end do
end subroutine time_stepping_loops
```
Most recurrences cannot be made fully parallel. Instead, look for a loop further out or further in to parallelize. You might be able to get more performance gains through unrolling.

**Anti Dependency - Write After Read**

Cross-iteration anti-dependence is created when variables are read then written in different iterations, as shown in the following example:

```fortran
subroutine anti_dependence (A,MAX)
  implicit none
  integer :: J, MAX
  real :: a(MAX), b(MAX)
  do J=1, MAX
    A(J)=A(J+1)
  end do
end subroutine anti_dependence
```

The above example is equivalent to the following lines for the first few iterations:

```plaintext
Sample Iterations
```
Output Dependency - Write After Write

Cross-iteration output dependence is where variables are written then rewritten in a different iteration. The following example illustrates this type of dependency:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>subroutine output_dependence (A,B,C,MAX)</td>
</tr>
<tr>
<td>implicit none</td>
</tr>
<tr>
<td>integer :: J,MAX</td>
</tr>
<tr>
<td>real :: a(MAX), b(MAX), c(MAX)</td>
</tr>
<tr>
<td>do J=1, MAX</td>
</tr>
<tr>
<td>A(J)=B(J)</td>
</tr>
<tr>
<td>A(J+1)=C(J)</td>
</tr>
<tr>
<td>end do</td>
</tr>
<tr>
<td>end subroutine output_dependence</td>
</tr>
</tbody>
</table>

The above example is equivalent to the following lines for the first few iterations:

<table>
<thead>
<tr>
<th>Sample Iterations</th>
</tr>
</thead>
</table>
Reductions

The Intel® compiler can successfully vectorize or software pipeline (SWP) most loops containing reductions on simple math operators like multiplication (*), addition (+), subtraction (-), and division (/). Reductions collapse array data to scalar data by using associative operations:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>subroutine reduction (sum,c,MAX)</td>
</tr>
<tr>
<td>implicit none</td>
</tr>
<tr>
<td>integer :: j,MAX</td>
</tr>
<tr>
<td>real :: sum, c(MAX)</td>
</tr>
<tr>
<td>do J=0, MAX</td>
</tr>
<tr>
<td>sum = sum + c(j)</td>
</tr>
<tr>
<td>end do</td>
</tr>
<tr>
<td>end subroutine reduction</td>
</tr>
</tbody>
</table>

The compiler might occasionally misidentify a reduction and report flow-, anti-, output-dependencies or sometimes loop-carried memory-dependency-edges; in such cases, the compiler will not vectorize or SWP the loop.

Prefetching with Options

The goal of prefetch insertion optimization is to reduce cache misses by providing hints to the processor about when data should be loaded into the cache. The prefetch optimization is enabled or disabled by the -opt-prefetch (Linux* and Mac OS® X) or /Qopt-prefetch (Windows*) compiler option. This option also allows you to specify the level of software prefetching.

To facilitate compiler optimization:

- Minimize use of global variables and pointers.
- Minimize use of complex control flow.
- Choose data types carefully and avoid type casting.

In addition to the -opt-prefetch (Linux and Mac OS X) or /Qopt-prefetch (Windows) option, an intrinsic subroutine mm_pread and compiler directive prefetch are also available.

The architecture affects the option behavior. For more information about the differences, see the following topic:
- *-opt-prefetch* compiler option

Optimization Support Features Overview

This section describes the language extensions that enable you to optimize your source code directly.

- Loop Support
- Loop Unrolling Support
- Vectorization Support
- Prefetch Support
- Software Pipelining (IA-64 Architecture)

See General Compiler Directives for more information about these directives.

Loop Support

**LOOP COUNT Directive**

The **LOOP COUNT** directive can affect heuristics used in vectorization, loop-transformations, and software pipelining (IA-64 architecture). The directive can specify the minimum, maximum, or average number of iterations for a *DO* loop. In addition, a list of commonly occurring values can be specified. This behavior might help the compiler generate multiple versions and perform complete unrolling.
The syntax for this directive supports the following syntax variations:

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>!DEC$ LOOP COUNT ( (n) )</td>
</tr>
<tr>
<td>!DEC$ LOOP COUNT = ( n )</td>
</tr>
<tr>
<td>or</td>
</tr>
<tr>
<td>!DEC$ LOOP COUNT ( (n1[,n2]...) )</td>
</tr>
<tr>
<td>!DEC$ LOOP COUNT = ( n1[,n2]... )</td>
</tr>
<tr>
<td>or</td>
</tr>
<tr>
<td>!DEC$ LOOP COUNT MAX( (n) ), AVG( (n) )</td>
</tr>
<tr>
<td>!DEC$ LOOP COUNT MAX=( n ), MIN=( n ), AVG=( n )</td>
</tr>
</tbody>
</table>

The syntax variations support the following arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( (n) ) or =( n )</td>
<td>Non-negative integer value. The compiler will attempt to iterate the next loop the number of times specified in ( n ); however, the number of iterations is not guaranteed.</td>
</tr>
<tr>
<td>( (n1[,n2]...) )</td>
<td>Non-negative integer values. The compiler will attempt to iterate the next loop the number of time specified by ( n1 ) or ( n2 ), or some other unspecified number of times. This behavior allows the compiler some flexibility in attempting to unroll the loop. The number of iterations is not guaranteed.</td>
</tr>
<tr>
<td>=( n1[,n2]... )</td>
<td></td>
</tr>
<tr>
<td>min( (n) ), max( (n) ), &gt;avg( (n) )</td>
<td>Non-negative integer values. Specify one or more in any order without duplication. The compiler insures the next loop iterates for the specified maximum, minimum, or average number ( (n1) ) of times. The specified number of iterations is guaranteed for min and max.</td>
</tr>
<tr>
<td>or</td>
<td></td>
</tr>
<tr>
<td>min=( n ), max=( n ), avg=( n )</td>
<td></td>
</tr>
</tbody>
</table>

You can specify more than one directive for a single loop; however, do not duplicate the directive.
The following example illustrates how to use the directive to iterate through the loop and enable software pipelining on IA-64 architectures.

### Using Loop Count (n)

```fortran
subroutine loop_count(a, b, N)
integer :: i, N, b(N), c(N)
!DEC$ LOOP COUNT (1000)
do i = 1, 1000
   b(i) = a(i) + 1
enddo
end subroutine loop_count
```

The following example illustrates how to use the directive to iterate through the loop a minimum of three, a maximum of ten, and average of five times.

### Using Loop Count min, max, avg

```fortran
!DEC$ LOOP COUNT MIN(3), MAX(10), AVG(5)
do i = 1, 15
   PRINT i
end do
```

### DISTRIBUTE POINT Directive

The `DISTRIBUTE POINT` directive instructs the compiler to prefer loop distribution at the location indicated. The syntax for this directive is shown below:

### Syntax

```fortran
!DEC$ DISTRIBUTE POINT
```

Loop distribution can cause large loops to be distributed into smaller ones. This strategy can enable software pipelining for the new, smaller loops (IA-64 architecture).

- If the directive is placed inside a loop, distribution is performed after the directive and any loop-carried dependency is ignored.
If the directive is placed before a loop, the compiler determines where to distribute the loops and observes data dependency. If they are placed inside the loop, the compiler supports multiple instances of the directive.

### Using distribute point

```fortran
subroutine dist1(a, b, c, d, N)
  integer :: i, N, a(N), b(N), c(N), d(N)
  !DEC$ DISTRIBUTE POINT
  do i = 1, N
    b(i) = a(i) + 1
    c(i) = a(i) + b(i)
    ! Compiler will decide where to distribute.
    ! Data dependency is observed.
    d(i) = c(i) + 1
  enddo
end subroutine dist1

subroutine dist2(a, b, c, d, N)
  integer :: i, N, a(N), b(N), c(N), d(N)
  do i = 1, N
    b(i) = a(i) + 1
    !DEC$ DISTRIBUTE POINT
    ! Distribution will start here, ignoring all
    ! loop-carried dependency.
    c(i) = a(i) + b(i)
    d(i) = c(i) + 1
  enddo
end subroutine dist2
```
Loop Unrolling Support

The UNROLL[n] directive tells the compiler how many times to unroll a counted loop. The general syntax for this directive is shown below:

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>!DEC$ UNROLL(n)</td>
</tr>
</tbody>
</table>

where \( n \) is an integer constant from 0 through 255.

The UNROLL directive must precede the DO statement for each DO loop it affects. If \( n \) is specified, the optimizer unrolls the loop \( n \) times. If \( n \) is omitted or if it is outside the allowed range, the optimizer assigns the number of times to unroll the loop.

This directive is supported only when option \(-O3\) (Linux* OS and Mac OS* X) or /O3 (Windows* OS) is used. The UNROLL directive overrides any setting of loop unrolling from the command line.

Currently, the directive can be applied only for the innermost loop nest. If applied to the outer loop nests, it is ignored. The compiler generates correct code by comparing \( n \) and the loop count.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>subroutine unroll(a, b, c, d)</td>
</tr>
<tr>
<td>integer :: i, b(100), c(100), d(100)</td>
</tr>
<tr>
<td>!DEC$ UNROLL(4)</td>
</tr>
<tr>
<td>do i = 1, 100</td>
</tr>
<tr>
<td>b(i) = a(i) + 1</td>
</tr>
<tr>
<td>d(i) = c(i) + 1</td>
</tr>
<tr>
<td>enddo</td>
</tr>
<tr>
<td>end subroutine unroll</td>
</tr>
</tbody>
</table>
Vectorization Support

IVDEP Directive

The IVDEP directive instructs the compiler to ignore assumed vector dependences. To ensure correct code, the compiler treats an assumed dependence as a proven dependence, which prevents vectorization. This directive overrides that decision. Use IVDEP only when you know that the assumed loop dependences are safe to ignore.

For example, if the expression \( j \geq 0 \) is always true in the code fragment below, the IVDEP directive can communicate this information to the compiler. This directive informs the compiler that the conservatively assumed loop-carried flow dependences for values \( j < 0 \) can be safely ignored:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>!DEC$ IVDEP</td>
</tr>
<tr>
<td>do i = 1, 100</td>
</tr>
<tr>
<td>( a(i) = a(i+j) )</td>
</tr>
<tr>
<td>enddo</td>
</tr>
</tbody>
</table>

NOTE. The proven dependences that prevent vectorization are not ignored, only assumed dependences are ignored.
The usage of the directive differs depending on the loop form, see examples below.

**Example: Loop 1**

```
do i
    = a(*) + 1
    a(*) =
enddo
```

**Example: Loop 2**

```
do i
    a(*) =
        = a(*) + 1
    enddo
```

For loops of the form 1, use old values of \( a \), and assume that there is no loop-carried flow dependencies from DEF to USE.

For loops of the form 2, use new values of \( a \), and assume that there is no loop-carried anti-dependencies from USE to DEF.
In both cases, it is valid to distribute the loop, and there is no loop-carried output dependency.

**Example 1**

```fortran
!DEC$ IVDEP
do j=1,n
   a(j) = a(j+m) + 1
enddo
```

**Example 2**

```fortran
!DEC$ IVDEP
do j=1,n
   a(j) = b(j) + 1
   b(j) = a(j+m) + 1
enddo
```

Example 1 ignores the possible backward dependencies and enables the loop to get software pipelined.

Example 2 shows possible forward and backward dependencies involving array `a` in this loop and creating a dependency cycle. With IVDEP, the backward dependencies are ignored.

IVDEP has options: `IVDEP:LOOP` and `IVDEP:BACK`. The `IVDEP:LOOP` option implies no loop-carried dependencies. The `IVDEP:BACK` option implies no backward dependencies.

The IVDEP directive is also used for IA-64 architecture based applications.

**Overriding the Efficiency Heuristics in the Vectorizer**

In addition to IVDEP directive, there are VECTOR directives that can be used to override the efficiency heuristics of the vectorizer:

- VECTOR ALWAYS
- NOVECTOR
- VECTOR ALIGNED
- VECTOR UNALIGNED
• VECTOR NONTEMPORAL

The VECTOR directives control the vectorization of the subsequent loop in the program, but the compiler does not apply them to nested loops. Each nested loop needs its own directive preceding it. You must place the vector directive before the loop control statement.

VECTOR ALWAYS and NOVECTOR Directives

The VECTOR ALWAYS directive overrides the efficiency heuristics of the vectorizer, but it only works if the loop can actually be vectorized, that is: use IVDEP to ignore assumed dependences.

The VECTOR ALWAYS directive can be used to override the default behavior of the compiler in the following situation. Vectorization of non-unit stride references usually does not exhibit any speedup, so the compiler defaults to not vectorizing loops that have a large number of non-unit stride references (compared to the number of unit stride references). The following loop has two references with stride 2.

Vectorization would be disabled by default, but the directive overrides this behavior.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>!DEC$ VECTOR ALWAYS</td>
</tr>
<tr>
<td>do i = 1, 100, 2</td>
</tr>
<tr>
<td>a(i) = b(i)</td>
</tr>
<tr>
<td>enddo</td>
</tr>
</tbody>
</table>

If, on the other hand, avoiding vectorization of a loop is desirable (if vectorization results in a performance regression rather than improvement), the NOVECTOR directive can be used in the source text to disable vectorization of a loop. For instance, the compiler vectorizes the following example loop by default. If this behavior is not appropriate, the NOVECTOR directive can be used, as shown below.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>!DEC$ NOVECTOR</td>
</tr>
<tr>
<td>do i = 1, 100</td>
</tr>
<tr>
<td>a(i) = b(i) + c(i)</td>
</tr>
<tr>
<td>enddo</td>
</tr>
</tbody>
</table>

VECTOR ALIGNED/UNALIGNED Directives
Like VECTOR ALWAYS, these directives also override the efficiency heuristics. The difference is that the qualifiers UNALIGNED and ALIGNED instruct the compiler to use, respectively, unaligned and aligned data movement instructions for all array references. This disables all the advanced alignment optimizations of the compiler, such as determining alignment properties from the program context or using dynamic loop peeling to make references aligned.

**NOTE.** The directives VECTOR [ALWAYS|UNALIGNED|ALIGNED] should be used with care. Overriding the efficiency heuristics of the compiler should only be done if the programmer is absolutely sure the vectorization will improve performance. Furthermore, instructing the compiler to implement all array references with aligned data movement instructions will cause a run-time exception in case some of the access patterns are actually unaligned.

**The VECTOR NONTEMPORAL Directive**

The VECTOR NONTEMPORAL directive results in streaming stores on the systems based on IA-32 and Intel® 64 architectures. A floating-point type loop together with the generated assembly are shown in the example below. For large \( n \), significant performance improvements result on a Pentium 4 system over a non-streaming implementation.
The following example shows the \texttt{VECTOR NONTEMPORAL} directive that directs the compiler to use streaming store on the array $a$ but not for the array $b$:

\begin{verbatim}
Example

subroutine set(a,b,n)
  integer i,n
  real a(n), b(n)
  !DEC$ VECTOR NONTEMPORAL (a)
!DEC$ VECTOR ALIGNED
  do i = 1, n
    a(i) = 1
    b(i) = 1
  enddo
end

program setit
  parameter(n=1024*1204)
  real a(n), b(n)
  integer i
  do i = 1, n
    a(i) = 0
  enddo
  call set(a,b,n)
  do i = 1, n
    if (a(i)+b(i).ne.2) then
      print *, 'failed nontemp.f', a(i), i
      stop
    endif
  enddo
  print *, 'passed nontemp.f'
\end{verbatim}
Prefetching Support

Data prefetching refers to loading data from a relatively slow memory into a relatively fast cache before the data is needed by the application. Data prefetch behavior depends on the architecture:

- **IA-64 architecture:** The Intel® compiler generally issues prefetch instructions when you specify `-O1`, `-O2`, and `-O3` (Linux*) or `/O1`, `/O2`, and `/O3` (Windows*).
- **IA-32 and Intel® 64 architectures:** The processor identifies simple, regular data access patterns and performs a hardware prefetch. The compiler will only issue prefetch instructions for more complicated data access patterns where a hardware prefetch is not expected.

Issuing prefetches improves performance in most cases; however, there are cases where issuing prefetch instructions might slow application performance. Experiment with prefetching; it can be helpful to turn prefetching on or off with a compiler option while leaving all other optimizations unaffected to isolate a suspected prefetch performance issue. See Prefetching with Options for information on using compiler options for prefetching data.

There are two primary methods of issuing prefetch instructions. One is by using compiler directives and the other is by using compiler intrinsics.

**PREFETCH and NOPREFETCH Directives**

The PREFETCH and NOPREFETCH directives are supported by Itanium® processors only. These directives assert that the data prefetches be generated or not generated for some memory references. This affects the heuristics used in the compiler.
If loop includes expression \( A(j) \), placing `PREFETCH` in front of the loop, instructs the compiler to insert prefetches for \( A(j + d) \) within the loop. \( d \) is the number of iterations ahead to prefetch the data and is determined by the compiler. This directive is supported with optimization levels of \(-O1\) (Linux*) or \(/O1\) (Windows*) or higher. Remember that \(-O2\) or \(/O2\) is the default optimization level.

**Example**

```fortran
!DEC$ NOPREFETCH c
!DEC$ PREFETCH a
    do i = 1, m
        b(i) = a(c(i)) + 1
    enddo
```
The following example is for IA-64 architecture only:

```fortran
Example

do j=1,lastrow-firstrow+1
  i = rowstr(j)
  iresidue = mod( rowstr(j+1)-i, 8 )
  sum = 0.d0
  !DEC$ NOPREFETCH a,p,colidx
  do k=i,i+iresidue-1
    sum = sum + a(k)*p(colidx(k))
  enddo
  !DEC$ NOPREFETCH colidx
  !DEC$ PREFETCH a:1:40
  !DEC$ PREFETCH p:1:20
  do k=i+iresidue, rowstr(j+1)-8, 8
    sum = sum + a(k )*p(colidx(k ))
      & + a(k+1)*p(colidx(k+1)) + a(k+2)*p(colidx(k+2))
      & + a(k+3)*p(colidx(k+3)) + a(k+4)*p(colidx(k+4))
      & + a(k+5)*p(colidx(k+5)) + a(k+6)*p(colidx(k+6))
      & + a(k+7)*p(colidx(k+7))
  enddo
  q(j) = sum
enddo
```

**Intrinsics**

Before inserting compiler intrinsics, experiment with all other supported compiler options and directives. Compiler intrinsics are less portable and less flexible than either a compiler option or compiler directives.
Directives enable compiler optimizations while intrinsics perform optimizations. As a result, programs with directives are more portable, because the compiler can adapt to different processors, while the programs with intrinsics may have to be rewritten/ported for different processors. This is because intrinsics are closer to assembly programming.

The compiler supports an intrinsic subroutine `mm_prefetch`. In contrast the way the `prefetch` directive enables a data prefetch from memory, the subroutine `mm_prefetch` prefetches data from the specified address on one memory cache line. The `mm_prefetch` subroutine is described in the Intel® Fortran Language Reference.

**Software Pipelining Support (IA-64 Architecture)**

The `SWP` directive indicates preference for loops to be software pipelined. The directive does not help data dependency, but overrides heuristics based on profile counts or unequal control flow.

The syntax for this directive is shown below:

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>!DEC$ SWP</td>
</tr>
</tbody>
</table>

The Software Pipelining optimization triggered by the `SWP` directive applies instruction scheduling to certain innermost loops, allowing instructions within a loop to be split into different stages, allowing increased instruction level parallelism.

This strategy can reduce the impact of long-latency operations, resulting in faster loop execution. Loops chosen for software pipelining are always innermost loops that do not contain procedure calls that are not inlined. Because the optimizer no longer considers fully unrolled loops as innermost loops, fully unrolling loops can allow an additional loop to become the innermost loop (see loop unrolling options).

You can view an optimization report to see whether software pipelining was applied (see Optimizer Report Generation).
The following example demonstrates one way of using the directive to instruct the compiler to attempt software pipelining.

<table>
<thead>
<tr>
<th>Example: Using SWP</th>
</tr>
</thead>
<tbody>
<tr>
<td>subroutine swp(a, b)</td>
</tr>
<tr>
<td>integer :: i, a(100), b(100)</td>
</tr>
<tr>
<td>!DEC$ SWP</td>
</tr>
<tr>
<td>do i = 1, m</td>
</tr>
<tr>
<td>if (a(i) .eq. 0)</td>
</tr>
<tr>
<td>then</td>
</tr>
<tr>
<td>b(i) = a(i) + 1</td>
</tr>
<tr>
<td>else</td>
</tr>
<tr>
<td>b(i) = a(i)/c(i)</td>
</tr>
<tr>
<td>endif</td>
</tr>
<tr>
<td>enddo</td>
</tr>
<tr>
<td>end subroutine swp</td>
</tr>
</tbody>
</table>

About Register Allocation

The Intel® Compiler for IA-32 and Intel® 64 architectures contains an advanced, region-based register allocator. Register allocation can be influenced using the -opt-ra-region-strategy (Linux* and Mac OS* X) and /Qopt-ra-region-strategy (Windows*) option.

The register allocation high-level strategy when compiling a routine is to partition the routine into regions, assign variables to registers or memory within each region, and resolve discrepancies at region boundaries. The overall quality of the allocation depends heavily on the region partitioning.

By default, the Intel Compiler selects the best region partitioning strategy, but the -opt-ra-region-strategy (Linux* and Mac OS X) and /Qopt-ra-region-strategy (Windows) option allows you to experiment with the other available allocation strategies, which might result in better performance in some cases. The option provides several different arguments that allow you to specify the following allocation strategies:

- routine = a region for each routine
• trace = a region for each trace
• loop = a region for each loop
• block = a region for each block
• default = the compiler selects best allocation strategy

See the /Qopt-ra-region-strategy (Windows) -opt-ra-region-strategy (Linux and Mac OS X) compiler option for additional information.

The option can affect compile time. Register allocation is a relatively costly operation, and the time spent in register allocation tends to grow as the number of regions increases. Expect relative compile time to increase in the order listed, from shortest to longest:

1. routine-based regions (shortest)
2. loop-based regions
3. trace-based regions
4. block-based regions (longest)

Trace-based regions tend to work very well when profile guided optimizations are enabled. The allocator is able to construct traces that accurately reflect the hot paths through the routine.

In the absence of profile information, loop-based regions tend to work well because the execution profile of a program tends to match its loop structure. In programs where the execution profile does not match the loop structure, routine- or block-based regions can produce better allocations.

Block-based regions provide maximum flexibility to the allocator and in many cases can produce the best allocation; however, the allocator is sometimes over-aggressive with block-based regions about allocating variables to registers; the behavior can lead to poor allocations in the IA-32 and Intel® 64 architectures where registers can be scarce resources.

**Register Allocation Example Scenarios**

Consider the following example, which illustrates a control flow that results from a simple if-then-else statement within a loop.
There are 3 variables in this loop: \( i \), \( s \), and \( n \). For this example, assume there are only two registers available to hold these three variables; one, or more, variable will need to be stored in memory for at least part of the loop.

The best choice depends on which path through the loop is more frequently executed. For example, if B1, B2, B4 is the hot path, keeping variables \( i \) and \( n \) in registers along that path and saving and restoring one of them in B3 to free up a register for \( s \) is the best strategy. That scenario avoids all memory accesses on the hot path. If B1, B3, B4 is the hot path, the best strategy is to keep variables \( i \) and \( s \) in registers and to store \( n \) in memory, since there are no assignments to \( n \) along the path. This strategy results in a single memory read on the hot path. If both paths are executed with equal frequency, the best strategy is to save and restore either \( i \) or \( n \) around B3 just like in the B1, B2, B4 case. That case avoids all memory accesses on one path and results in a single memory write and a single memory read on the other path.

The compiler generates two significantly different allocations for this example depending on the region strategy; the preferred result depends on the runtime behavior of the program, which may not be known at compile time.

With a routine- or a loop-based strategy, all four blocks will be allocated together. The compiler picks a variable to store in memory based on expected costs. In this example, the allocator will probably select variable \( n \), resulting in a memory write in B2 and a memory read in B3.
With a trace-based strategy, the compiler uses estimates of execution frequency to select the most frequently executed path through the loop. When profile guided optimizations are enabled the estimates are based on the concrete information about the runtime behavior of the instrumented program. If the PGO information accurately reflects typical application behavior, the compiler produces highly accurate traces. In other cases, the traces are not necessarily an accurate reflection of the hot paths through the code.

Suppose in this example that the compiler selects B1, B2, B4 path as the hot trace. The compiler will assign these three blocks to one region, and B3 will be in a separate region. There are only two variables in the larger region, so both may be kept in registers. In the region containing just B3 either \( i \) or \( n \) are stored in memory, and the compiler makes an arbitrary choice between the two variables. In a block-based strategy, each block is a region. In the B1, B2, B4 path there are sufficient registers to hold the two variables: \( i \) and \( n \). The region containing B3 is treated just like the trace-based case; either \( i \) or \( n \) will be stored in memory.
Coding Guidelines for Intel® Architectures

This topic provides general guidelines for coding practices and techniques for using:

- IA-32 and Intel® 64 architectures supporting MMX™ technology and Intel® Streaming SIMD Extensions Streaming SIMD Extensions (SSE), Streaming SIMD Extensions 2 (SSE2), Streaming SIMD Extensions 3 (SSE3), and Streaming SIMD Extensions 4 (SSE4)
- IA-64 architecture

This section describes practices, tools, coding rules and recommendations associated with the architecture features that can improve the performance for processors based on IA-32, Intel® 64, and IA-64 architectures.

**NOTE.** If a guideline refers to a particular architecture only, this architecture is explicitly named. The default is for IA-32 architectures.

Performance of compiler-generated code may vary from one compiler to another. Intel® Fortran Compiler generates code that is optimized for Intel architectures. You can significantly improve performance by using various compiler optimization options. In addition, you can help the compiler to optimize your Fortran program by following the guidelines described in this section.

To achieve optimum processor performance in your Fortran application, do the following:

- avoiding memory access stalls
- ensuring good floating-point performance
- ensuring good SIMD integer performance
- using vectorization

The following sections summarize and describe coding practices, rules and recommendations associated with the features that will contribute to optimizing the performance on Intel architecture-based processors.
Memory Access

The Intel compiler lays out arrays in column-major order. For example, in a two-dimensional array, elements \( A(22,34) \) and \( A(23,34) \) are contiguous in memory. For best performance, code arrays so that inner loops access them in a contiguous manner.

Consider the following examples. The code in example 1 will likely have higher performance than the code in example 2.

**Example 1**

```fortran
subroutine contiguous(a, b, N)
    integer :: i, j, N, a(N,N), b(N,N)
    do j = 1, N
        do i = 1, N
            b(i, j) = a(i, j) + 1
        end do
    end do
end subroutine contiguous
```

The code above illustrates access to arrays \( A \) and \( B \) in the inner loop \( i \) in a contiguous manner which results in good performance; however, the following example illustrates access to arrays \( A \) and \( B \) in inner loop \( j \) in a non-contiguous manner which results in poor performance.

**Example 2**

```fortran
subroutine non_contiguous(a, b, N)
    integer :: i, j, N, a(N,N), b(N,N)
    do i = 1, N
        do j = 1, N
            b(i, j) = a(i, j) + 1
        end do
    end do
end subroutine non_contiguous
```
The compiler can transform the code so that inner loops access memory in a contiguous manner. To do that, you need to use advanced optimization options, such as `-O3` (Linux* OS) or `/O3` (Windows* OS) for IA-32, Intel® 64, and IA-64 architectures, and `-O3` (Linux) or `/O3` (Windows) and `-ax` (Linux) or `/Qax` (Windows) for IA-32 architecture only.

**Memory Layout**

Alignment is an increasingly important factor in ensuring good performance. Aligned memory accesses are faster than unaligned accesses. If you use the interprocedural optimization on multiple files, the `-ipo` (Linux) or `/Qipo` (Windows) option, the compiler analyzes the code and decides whether it is beneficial to pad arrays so that they start from an aligned boundary. Multiple arrays specified in a single common block can impose extra constraints on the compiler.

For example, consider the following `COMMON` statement:

```
Example 3

COMMON /AREA1/ A(200), X, B(200)
```

If the compiler added padding to align `A(1)` at a 16-byte aligned address, the element `B(1)` would not be at a 16-byte aligned address. So it is better to split `AREA1` as follows.

```
Example 4

COMMON /AREA1/ A(200)
COMMON /AREA2/ X
COMMON /AREA3/ B(200)
```

The above code provides the compiler maximum flexibility in determining the padding required for both `A` and `B`.

**Setting Data Type and Alignment**

Alignment of data affects these kinds of variables:

- Those that are dynamically allocated. (Dynamically allocated data allocated with `ALLOCATE` is 8-byte aligned.)
- Those that are members of a data structure
- Those that are global or local variables
Those that are parameters passed on the stack

For best performance, align data as follows:

- Align 8-bit data at any address.
- Align 16-bit data to be contained within an aligned four byte word.
- Align 32-bit data so that its base address is a multiple of four.
- Align 64-bit data so that its base address is a multiple of eight.
- Align 128-bit data so that its base address is a multiple of sixteen (8-byte boundaries).

**Causes of Unaligned Data and Ensuring Natural Alignment**

For optimal performance, make sure your data is aligned naturally. A natural boundary is a memory address that is a multiple of the data item's size. For example, a `REAL (KIND=8)` data item aligned on natural boundaries has an address that is a multiple of 8. An array is aligned on natural boundaries if all of its elements are so aligned.

All data items whose starting address is on a natural boundary are naturally aligned. Data not aligned on a natural boundary is called unaligned data.

Although the Intel® compiler naturally aligns individual data items when it can, certain Fortran statements can cause data items to become unaligned.

You can use the align command-option to ensure naturally aligned data, but you should check and consider reordering data declarations of data items within common blocks, derived-type structures, and record structures as follows:

- Carefully specify the order and sizes of data declarations to ensure naturally aligned data.
- Start with the largest size numeric items first, followed by smaller size numeric items, and then non-numeric (character) data.

The `!DEC$ ATTRIBUTES ALIGN` directive specifies the byte alignment for a variable.

Common blocks (COMMON statement), derived-type data, and record structures (RECORD statement) usually contain multiple items within the context of the larger structure.

The following statements can cause unaligned data:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Common blocks (COMMON statement)</td>
<td>commons or dcommons</td>
<td>The order of variables in the COMMON statement determines their storage</td>
</tr>
<tr>
<td>Statement</td>
<td>Options</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Derived-type (user-defined) data</td>
<td>records or</td>
<td>Derived-type data items are declared after a <code>TYPE</code> statement.</td>
</tr>
<tr>
<td></td>
<td>sequence</td>
<td>If your data includes derived-type data structures, you should use the <code>-align records</code> (Linux) or <code>/align:records</code> (Windows) option, unless you are sure that the data items in the derived-type structures will be naturally aligned. If you omit the sequence statement, the <code>-align records</code> (Linux) or <code>/align:records</code> (Windows) option (default) ensures all data items are naturally aligned. If you specify the <code>SEQUENCE</code> statement, the <code>-align records</code> (Linux) or <code>/align:records</code> (Windows) option is prevented from adding necessary padding to order. Unless you are sure that the data items in the common block will be naturally aligned, specify either <code>-align commons</code> or <code>/align:commons</code> (Linux*) or <code>/align:dcommons</code> (Windows*), depending on the largest data size used.</td>
</tr>
</tbody>
</table>

* Linux

* Windows
<table>
<thead>
<tr>
<th>Statement</th>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Record structures (RECORD and STRUCTURE statements)</td>
<td>record or structure</td>
<td><strong>avoid unaligned data (data items are packed) unless you specify</strong> <code>SEQUENCE</code>. <strong>When you use</strong> <code>SEQUENCE</code>, you should specify data declaration order so that all data items are naturally aligned. Intel Fortran record structures usually contain multiple data items. The order of variables in the <code>STRUCTURE</code> statement determines their storage order. The <code>RECORD</code> statement names the record structure. Record structures are an Intel Fortran language extension. If your data includes record structures, you should use the <code>-align records</code> (Linux) or <code>/align:records</code> (Windows) option, unless you are sure that the data items in the record structures will be naturally aligned.</td>
</tr>
<tr>
<td>EQUIVALENCE statements</td>
<td></td>
<td><strong>EQUIVALENCE statements can force unaligned data or cause data to span natural boundaries. For more information, see the Intel® Fortran Language Reference.</strong></td>
</tr>
</tbody>
</table>

To avoid unaligned data in a common block, derived-type data, or record structure (extension), use one or both of the following:
- For new programs or for programs where the source code declarations can be modified easily, plan the order of data declarations with care. For example, you should order variables in a `COMMON` statement such that numeric data is arranged from largest to smallest, followed by any character data (see the data declaration rules in Ordering Data Declarations to Avoid Unaligned Data below.

- For existing programs where source code changes are not easily done or for array elements containing derived-type or record structures, you can use command line options to request that the compiler align numeric data by adding padding spaces where needed.

Other possible causes of unaligned data include unaligned actual arguments and arrays that contain a derived-type structure or Intel Fortran record structure as detailed below.

- When actual arguments from outside the program unit are not naturally aligned, unaligned data access occurs. Intel Fortran assumes all passed arguments are naturally aligned and has no information at compile time about data that will be introduced by actual arguments during program execution.

- For arrays where each array element contains a derived-type structure or Intel Fortran record structure, the size of the array elements may cause some elements (but not the first) to start on an unaligned boundary.

- Even if the data items are naturally aligned within a derived-type structure without the `SEQUENCE` statement or a record structure, the size of an array element might require use of the `-align records` (Linux) or `/align:records` (Windows) option to supply needed padding to avoid some array elements being unaligned.

- If you specify `-align norecords` (Linux) or `/align:norecords` (Windows) or specify `-vms` (Linux) or `/Qvms` (Windows) without `RECORDS` no padding bytes are added between array elements. If array elements each contain a derived-type structure with the `SEQUENCE` statement, array elements are packed without padding bytes regardless of the Fortran command options specified. In this case, some elements will be unaligned.

- When the `-align records` (Linux) or `/align:records` (Windows) option is in effect, the number of padding bytes added by the compiler for each array element is dependent on the size of the largest data item within the structure. The compiler determines the size of the array elements as an exact multiple of the largest data item in the derived-type structure without the `SEQUENCE` statement or a record structure. The compiler then adds the appropriate number of padding bytes. For instance, if a structure contains an 8-byte floating-point number followed by a 3-byte character variable, each element contains five bytes of padding (16 is an exact multiple of 8). However, if the structure contains one 4-byte floating-point number, one 4-byte integer, followed by a 3-byte character variable, each element would contain one byte of padding (12 is an exact multiple of 4).
Checking for Inefficient Unaligned Data

During compilation, the Intel compiler naturally aligns as much data as possible. Exceptions that can result in unaligned data are described above.

Because unaligned data can slow run-time performance, it is worthwhile to:

- Double-check data declarations within common block, derived-type data, or record structures to ensure all data items are naturally aligned (see the data declaration rules in the subsection below). Using modules to contain data declarations can ensure consistent alignment and use of such data.
- Avoid the `EQUIVALENCE` statement or use it in a manner that cannot cause unaligned data or data spanning natural boundaries.
- Ensure that passed arguments from outside the program unit are naturally aligned.
- Check that the size of array elements containing at least one derived-type data or record structure (extension) cause array elements to start on aligned boundaries (see the previous subsection).
- There are two ways unaligned data might be reported:
  - During compilation, warning messages are issued for any data items that are known to be unaligned (unless you specify the `-warn noalignments` (or `-warn none`) (Linux) or `/warn:noalignments` (or `/warn:none`) (Windows) option that suppresses all warnings).
  - During program execution, warning messages are issued for any data that is detected as unaligned. The message includes the address of the unaligned access.

Consider the following run-time message:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unaligned access pid=24821 &lt;a.out&gt; va=140000154, pc=3ff80805d60, ra=1200017bc</td>
</tr>
</tbody>
</table>

This message shows that:

- The statement accessing the unaligned data (program counter) is located at 3ff80805d60
- The unaligned data is located at address 140000154
Ordering Data Declarations to Avoid Unaligned Data

For new programs or when the source declarations of an existing program can be easily modified, plan the order of your data declarations carefully to ensure the data items in a common block, derived-type data, record structure, or data items made equivalent by an EQUVALENCE statement will be naturally aligned.

Use the following rules to prevent unaligned data:

- Always define the largest size numeric data items first.
- If your data includes a mixture of character and numeric data, place the numeric data first.
- Add small data items of the correct size (or padding) before otherwise unaligned data to ensure natural alignment for the data that follows.

When declaring data, consider using explicit length declarations, such as specifying a KIND parameter. For example, specify INTEGER(KIND=4) (or INTEGER(4)) rather than INTEGER. If you do use a default size (such as INTEGER, LOGICAL, COMPLEX, and REAL), be aware that the following compiler options can change the size of an individual field's data declaration size and thus can alter the data alignment of a carefully planned order of data declarations:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Compiler Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows*</td>
<td>/4I or /4R</td>
</tr>
<tr>
<td>Linux* and Mac OS* X</td>
<td>-integer_size or -real_size</td>
</tr>
</tbody>
</table>

Using the suggested data declaration guidelines minimizes the need to use the -align keyword (Linux) or /align:keyword (Windows) options to add padding bytes to ensure naturally aligned data. In cases where the -align keyword (Linux) or /align:keyword (Windows) options are still needed, using the suggested data declaration guidelines can minimize the number of padding bytes added by the compiler.
Arranging Data Items in Common Blocks

The order of data items in a COMMON statement determines the order in which the data items are stored. Consider the following declaration of a common block named X:

Example

```
logical (kind=2) flag
integer      iarry_i(3)
character(len=5) name_ch
common /x/ flag, iarry_i(3), name_ch
```

As shown in Figure 1-1, if you omit the appropriate Fortran command options, the common block will contain unaligned data items beginning at the first array element of IARRY_I.

Figure 22: Figure 1-1 Common Block with Unaligned Data

As shown in Figure 1-2, if you compile the program units that use the common block with the -align commons (Linux) or /align:commons (Windows) option, data items will be naturally aligned.

Figure 23: Figure 1-2 Common Block with Naturally Aligned Data

Because the common block X contains data items whose size is 32 bits or smaller, specify the -align commons (Linux) or /align:commons (Windows) option. If the common block contains data items whose size might be larger than 32 bits (such as REAL (KIND=8) data), use the -align dcommons (Linux) or /align:dcommons (Windows) option.
If you can easily modify the source files that use the common block data, define the numeric variables in the `COMMON` statement in descending order of size and place the character variable last. This provides more portability, ensures natural alignment without padding, and does not require the Fortran command options `-align commons (Linux)` or `-align dcommons (Linux)` or `/align commons (Windows)` or `/align:dcommons (Windows):

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL (KIND=2) FLAG</td>
</tr>
<tr>
<td>INTEGER IARRY_I(3)</td>
</tr>
<tr>
<td>CHARACTER(LEN=5) NAME_CH</td>
</tr>
<tr>
<td>COMMON /X/ IARRY_I(3), FLAG, NAME_CH</td>
</tr>
</tbody>
</table>

As shown in Figure 1-3, if you arrange the order of variables from largest to smallest size and place character data last, the data items will be naturally aligned.

**Figure 24: Figure 1-3 Common Block with Naturally Aligned Reordered Data**

When modifying or creating all source files that use common block data, consider placing the common block data declarations in a module so the declarations are consistent. If the common block is not needed for compatibility (such as file storage or Fortran 77 use), you can place the data declarations in a module without using a `COMMON` block.

**Arranging Data Items in Derived-Type Data**

Like common blocks, derived-type data may contain multiple data items (members). Data item components within derived-type data will be naturally aligned on up to 64-bit boundaries, with certain exceptions related to the use of the `SEQUENCE` statement and Fortran options.

Intel Fortran stores a derived data type as a linear sequence of values, as follows:

- If you specify the `SEQUENCE` statement, the first data item is in the first storage location and the last data item is in the last storage location. The data items appear in the order in which they are declared. The Fortran options have no effect on unaligned data, so data...
declarations must be carefully specified to naturally align data. The -align sequence (Linux) or /align:sequence (Windows) option specifically aligns data items in a SEQUENCE derived-type on natural boundaries.

- If you omit the SEQUENCE statement, the Intel Fortran adds the padding bytes needed to naturally align data item components, unless you specify the -align norecords (Linux) or /align:norecords (Windows) option.

Consider the following declaration of array CATALOG_SPRING of derived-type PART_DT:

```fortran
MODULE DATA_DEFS
  TYPE PART_DT
    INTEGER IDENTIFIER
    REAL WEIGHT
    CHARACTER(LEN=15) DESCRIPTION
  END TYPE PART_DT
  TYPE (PART_DT) CATALOG_SPRING(30)
  ...
END MODULE DATA_DEFS
```

As shown in Figure 1-4, the largest numeric data items are defined first and the character data type is defined last. There are no padding characters between data items and all items are naturally aligned. The trailing padding byte is needed because CATALOG_SPRING is an array; it is inserted by the compiler when the -align records (Linux) or /align:records (Windows) option is in effect.

**Figure 25: Figure 1-4 Derived-Type Naturally Aligned Data (in CATALOG_SPRING : (,))**
**Arranging Data Items in Intel Fortran Record Structures**

Intel Fortran supports record structures provided by Intel Fortran. Intel Fortran record structures use the RECORD statement and optionally the STRUCTURE statement, which are extensions to the Fortran 77 and Fortran standards. The order of data items in a STRUCTURE statement determines the order in which the data items are stored.

Intel Fortran stores a record in memory as a linear sequence of values, with the record's first element in the first storage location and its last element in the last storage location. Unless you specify `-align norecords` (Linux) or `/align:norecords` (Windows) padding bytes are added if needed to ensure data fields are naturally aligned.

The following example contains a structure declaration, a RECORD statement, and diagrams of the resulting records as they are stored in memory:

```fortran
Example

STRUCTURE /STRA/
   CHARACTER*1 CHR
   INTEGER*4 INT
END STRUCTURE
...
RECORD /STRA/ REC
```

Figure 1-5 shows the memory diagram of record REC for naturally aligned records.

**Figure 26: Figure 1-5 Memory Diagram of REC for Naturally Aligned Records**

**Using Arrays Efficiently**

This topic discusses how to efficiently access arrays and pass array arguments.
Accessing Arrays Efficiently

Many of the array access efficiency techniques described in this section are applied automatically by the Intel Fortran loop transformation optimizations. Several aspects of array use can improve run-time performance; the following sections discuss the most important aspects.

Perform the fewest operations necessary

The fastest array access occurs when contiguous access to the whole array or most of an array occurs. Perform one or a few array operations that access all of the array or major parts of an array instead of numerous operations on scattered array elements. Rather than use explicit loops for array access, use elemental array operations, such as the following line that increments all elements of array variable A:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>A = A + 1</td>
</tr>
</tbody>
</table>

When reading or writing an array, use the array name and not a DO loop or an implied DO-loop that specifies each element number. Fortran 95/90 array syntax allows you to reference a whole array by using its name in an expression.

For example:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL :: A(100,100)</td>
</tr>
<tr>
<td>A = 0.0</td>
</tr>
<tr>
<td>A = A + 1 ! Increment all elements</td>
</tr>
<tr>
<td>! of A by 1</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>WRITE (8) A ! Fast whole array use</td>
</tr>
</tbody>
</table>
Similarly, you can use derived-type array structure components, such as:

```
Example

TYPE X
  INTEGER A(5)
END TYPE X
...
TYPE (X) Z
WRITE (8) Z%A ! Fast array structure
! component use
```

**Access arrays using the proper array syntax**

Make sure multidimensional arrays are referenced using proper array syntax and are traversed in the natural ascending storage order, which is column-major order for Fortran. With column-major order, the leftmost subscript varies most rapidly with a stride of one. Whole array access uses column-major order.

Avoid row-major order, as is done by C, where the rightmost subscript varies most rapidly. For example, consider the nested `DO` loops that access a two-dimension array with the `J` loop as the innermost loop:

```
Example

INTEGER X(3,5), Y(3,5), I, J
Y = 0
DO I=1,3 ! I outer loop varies slowest
  DO J=1,5 ! J inner loop varies fastest
    X (I,J) = Y(I,J) + 1
  END DO
END DO
```
Since \( J \) varies the fastest and is the second array subscript in the expression \( X(I,J) \), the array is accessed in row-major order. To make the array accessed in natural column-major order, examine the array algorithm and data being modified. Using arrays \( X \) and \( Y \), the array can be accessed in natural column-major order by changing the nesting order of the \texttt{DO} loops so the innermost loop variable corresponds to the leftmost array dimension:

```
Example

    INTEGER X(3,5), Y(3,5), I, J
    Y = 0
    DO J=1,5 ! J outer loop varies slowest
        DO I=1,3 ! I inner loop varies fastest
            X(I,J) = Y(I,J) + 1
        END DO
    END DO

    ! Efficient column-major storage order
    END PROGRAM
```

The Intel Fortran whole array access (\( X = Y + 1 \)) uses efficient column major order. However, if the application requires that \( J \) vary the fastest or if you cannot modify the loop order without changing the results, consider modifying the application to use a rearranged order of array dimensions. Program modifications include rearranging the order of:

- Dimensions in the declaration of the arrays \( X(5,3) \) and \( Y(5,3) \)
- The assignment of \( X(J,I) \) and \( Y(J,I) \) within the \texttt{DO} loops
• All other references to arrays \( X \) and \( Y \)

In this case, the original \texttt{DO} loop nesting is used where \( J \) is the innermost loop:

ew devotion

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER ( X(5,3), Y(5,3), I, J )</td>
</tr>
<tr>
<td>( Y = 0 )</td>
</tr>
<tr>
<td>\textbf{DO} ( I=1,3 ) ! I outer loop varies slowest</td>
</tr>
<tr>
<td>\textbf{DO} ( J=1,5 ) ! J inner loop varies fastest</td>
</tr>
<tr>
<td>( X(J,I) = Y(J,I) + 1 )</td>
</tr>
<tr>
<td>! Efficient column-major storage order</td>
</tr>
<tr>
<td>\textbf{END DO} ! (leftmost subscript varies fastest)</td>
</tr>
<tr>
<td>\textbf{END DO}</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>\textbf{END PROGRAM}</td>
</tr>
</tbody>
</table>

Code written to access multidimensional arrays in row-major order (like C) or random order can often make inefficient use of the CPU memory cache. For more information on using natural storage order during record, see Improving I/O Performance.

**Use available intrinsics**

Whenever possible, use Fortran array intrinsic procedures instead of creating your own routines to accomplish the same task. Fortran array intrinsic procedures are designed for efficient use with the various Intel Fortran run-time components.

Using the standard-conforming array intrinsics can also make your program more portable.

**Avoid leftmost array dimensions**

With multidimensional arrays where access to array elements will be noncontiguous, avoid leftmost array dimensions that are a power of two (such as 256, 512).
Since the cache sizes are a power of 2, array dimensions that are also a power of 2 may make inefficient use of cache when array access is noncontiguous. If the cache size is an exact multiple of the leftmost dimension, your program will probably make use of the cache less efficient. This does not apply to contiguous sequential access or whole array access.

One work-around is to increase the dimension to allow some unused elements, making the leftmost dimension larger than actually needed. For example, increasing the leftmost dimension of A from 512 to 520 would make better use of cache:

```fortran
Example

REAL A (512,100)
DO I = 2,511
  DO J = 2,99
    A(I,J)=(A(I+1,J-1) + A(I-1, J+1)) * 0.5
  END DO
END DO
```

In this code, array A has a leftmost dimension of 512, a power of two. The innermost loop accesses the rightmost dimension (row major), causing inefficient access. Increasing the leftmost dimension of A to 520 (REAL A (520,100)) allows the loop to provide better performance, but at the expense of some unused elements.

Because loop index variables I and J are used in the calculation, changing the nesting order of the DO loops changes the results.

For more information on arrays and their data declaration statements, see the *Intel® Fortran Language Reference*.

**Passing Array Arguments Efficiently**

In Fortran, there are two general types of array arguments:

- **Explicit-shape arrays** (introduced with Fortran 77); for example, `A(3,4)` and `B(0:*)`

  These arrays have a fixed rank and extent that is known at compile time. Other dummy argument (receiving) arrays that are not deferred-shape (such as assumed-size arrays) can be grouped with explicit-shape array arguments.

- **Deferred-shape arrays** (introduced with Fortran 95/90); for example, `C(:, :)`
Types of deferred-shape arrays include array pointers and allocatable arrays. Assumed-shape array arguments generally follow the rules about passing deferred-shape array arguments.

When passing arrays as arguments, either the starting (base) address of the array or the address of an array descriptor is passed:

- When using explicit-shape (or assumed-size) arrays to receive an array, the starting address of the array is passed.
- When using deferred-shape or assumed-shape arrays to receive an array, the address of the array descriptor is passed (the compiler creates the array descriptor).

Passing an assumed-shape array or array pointer to an explicit-shape array can slow run-time performance. This is because the compiler needs to create an array temporary for the entire array. The array temporary is created because the passed array may not be contiguous and the receiving (explicit-shape) array requires a contiguous array. When an array temporary is created, the size of the passed array determines whether the impact on slowing run-time performance is slight or severe.

The following table summarizes what happens with the various combinations of array types. The amount of run-time performance inefficiency depends on the size of the array.

<table>
<thead>
<tr>
<th>Dummy Argument Array Types (choose one)</th>
<th>Actual Argument Array Types (choose one)</th>
<th>Explicit-Shape Arrays</th>
<th>Deferred-Shape and Assumed-Shape Arrays</th>
</tr>
</thead>
</table>
Deferred-Shape and Assumed-Shape Arrays

Result when using this combination: When passing an allocatable array, very efficient. Does not use an array temporary. Does not pass an array descriptor. Interface block optional.

When not passing an allocatable array, not efficient. Instead use allocatable arrays whenever possible.

Result when using this combination: Efficient. Requires an assumed-shape or array pointer as dummy argument.

Does not use an array temporary. Passes an array descriptor.

Requires an interface block.

Improving I/O Performance

Improving overall I/O performance can minimize both device I/O and actual CPU time. The techniques listed in this topic can significantly improve performance in many applications.

An I/O flow problems limit the maximum speed of execution by being the slowest process in an executing program. In some programs, I/O is the bottleneck that prevents an improvement in run-time performance. The key to relieving I/O problems is to reduce the actual amount of CPU and I/O device time involved in I/O.

The problems can be caused by one or more of the following:

- A dramatic reduction in CPU time without a corresponding improvement in I/O time.
- Such coding practices as:
  - Unnecessary formatting of data and other CPU-intensive processing
  - Unnecessary transfers of intermediate results
  - Inefficient transfers of small amounts of data
  - Application requirements

Improved coding practices can minimize actual device I/O, as well as the actual CPU time. Intel offers software solutions to system-wide problems like minimizing device I/O delays.
Use Unformatted Files Instead of Formatted Files

Use unformatted files whenever possible. Unformatted I/O of numeric data is more efficient and more precise than formatted I/O. Native unformatted data does not need to be modified when transferred and will take up less space on an external file.

Conversely, when writing data to formatted files, formatted data must be converted to character strings for output, less data can transfer in a single operation, and formatted data may lose precision if read back into binary form.

To write the array $A(25,25)$ in the following statements, $S1$ is more efficient than $S2$:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$S1$</td>
</tr>
<tr>
<td>WRITE (7) A</td>
</tr>
<tr>
<td>$S2$</td>
</tr>
<tr>
<td>WRITE (7,100) A</td>
</tr>
<tr>
<td>100</td>
</tr>
<tr>
<td>FORMAT (25(' ',25F5.21))</td>
</tr>
</tbody>
</table>

Although formatted data files are more easily ported to other systems, Intel Fortran can convert unformatted data in several formats; see Little-endian-to-Big-endian Conversion (IA-32 architecture).

Write Whole Arrays or Strings

To eliminate unnecessary overhead, write whole arrays or strings at one time rather than individual elements at multiple times. Each item in an I/O list generates its own calling sequence. This processing overhead becomes most significant in implied-DO loops. When accessing whole arrays, use the array name (Fortran array syntax) instead of using implied-DO loops.

Write Array Data in the Natural Storage Order

Use the natural ascending storage order whenever possible. This is column-major order, with the leftmost subscript varying fastest and striding by 1. (See Accessing Arrays Efficiently.) If a program must read or write data in any other order, efficient block moves are inhibited.

If the whole array is not being written, natural storage order is the best order possible.

If you must use an unnatural storage order, in certain cases it might be more efficient to transfer the data to memory and reorder the data before performing the I/O operation.
Use Memory for Intermediate Results

Performance can improve by storing intermediate results in memory rather than storing them in a file on a peripheral device. One situation that may not benefit from using intermediate storage is when there is a disproportionately large amount of data in relation to physical memory on your system. Excessive page faults can dramatically impede virtual memory performance.

Linux*: If you are primarily concerned with the CPU performance of the system, consider using a memory file system (mfs) virtual disk to hold any files your code reads or writes.

Enable Implied-DO Loop Collapsing

DO loop collapsing reduces a major overhead in I/O processing. Normally, each element in an I/O list generates a separate call to the Intel Fortran run-time library (RTL). The processing overhead of these calls can be most significant in implied-DO loops.

Intel Fortran reduces the number of calls in implied-DO loops by replacing up to seven nested implied-DO loops with a single call to an optimized run-time library I/O routine. The routine can transmit many I/O elements at once.

Loop collapsing can occur in formatted and unformatted I/O, but only if certain conditions are met:

- The control variable must be an integer. The control variable cannot be a dummy argument or contained in an EQUIVALENCE or VOLATILE statement. Intel Fortran must be able to determine that the control variable does not change unexpectedly at run time.
- The format must not contain a variable format expression.

For information on the VOLATILE attribute and statement, see the Intel® Fortran Language Reference.

Use of Variable Format Expressions

Variable format expressions (an Intel Fortran extension) are almost as flexible as run-time formatting, but they are more efficient because the compiler can eliminate run-time parsing of the I/O format. Only a small amount of processing and the actual data transfer are required during run time.
On the other hand, run-time formatting can impair performance significantly. For example, in the following statements, S1 is more efficient than S2 because the formatting is done once at compile time, not at run time:

### Example

<table>
<thead>
<tr>
<th>Statement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>S1 WRITE (6,400) (A(I), I=1,N)</td>
<td></td>
</tr>
<tr>
<td>400 FORMAT (1X, &lt;N&gt; F5.2)</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>S2 WRITE (CHFMT,500) '(1X,,N,'F5.2)'</td>
<td></td>
</tr>
<tr>
<td>500 FORMAT (A,I3,A)</td>
<td></td>
</tr>
<tr>
<td>WRITE (6,FMT=CHFMT) (A(I), I=1,N)</td>
<td></td>
</tr>
</tbody>
</table>

### Efficient Use of Record Buffers and Disk I/O

Records being read or written are transferred between the user's program buffers and one or more disk block I/O buffers, which are established when the file is opened by the Intel Fortran RTL. Unless very large records are being read or written, multiple logical records can reside in the disk block I/O buffer when it is written to disk or read from disk, minimizing physical disk I/O.

You can specify the size of the disk block physical I/O buffer by using the `OPEN` statement `BLOCKSIZE` specifier; the default size can be obtained from `fstat(2)`. If you omit the `BLOCKSIZE` specifier in the `OPEN` statement, it is set for optimal I/O use with the type of device the file resides on (with the exception of network access).

The `OPEN` statement `BUFFERCOUNT` specifier specifies the number of I/O buffers. The default for `BUFFERCOUNT` is 1. Any experiments to improve I/O performance should increase the `BUFFERCOUNT` value and not the `BLOCKSIZE` value, to increase the amount of data read by each disk I/O.

If the `OPEN` statement has `BLOCKSIZE` and `BUFFERCOUNT` specifiers, then the internal buffer size in bytes is the product of these specifiers. If the `open` statement does not have these specifiers, then the default internal buffer size is 8192 bytes. This internal buffer will grow to hold the largest single record, but will never shrink.
The default for the Fortran run-time system is to use unbuffered disk writes. That is, by default, records are written to disk immediately as each record is written instead of accumulating in the buffer to be written to disk later.

To enable buffered writes (that is, to allow the disk device to fill the internal buffer before the buffer is written to disk), use one of the following:

- The OPEN statement BUFFERED specifier
- The -assume buffered_io (Linux*) or /assume:buffered_io (Windows*) option of the ASSUME command
- The FORT_BUFFERED run-time environment variable

The OPEN statement BUFFERED specifier takes precedence over the -assume buffered_io (Linux) or /assume:buffered_io (Windows) option. If neither one is set (which is the default), the FORT_BUFFERED environment variable is tested at run time.

The OPEN statement BUFFERED specifier applies to a specific logical unit. In contrast, the -assume nobuffered_io (Linux) or /assume:nobuffered_io (Windows) option and the FORT_BUFFERED environment variable apply to all Fortran units.

Using buffered writes usually makes disk I/O more efficient by writing larger blocks of data to the disk less often. However, a system failure when using buffered writes can cause records to be lost, since they might not yet have been written to disk. (Such records would have been written to disk with the default unbuffered writes.)

When performing I/O across a network, be aware that the size of the block of network data sent across the network can impact application efficiency. When reading network data, follow the same advice for efficient disk reads, by increasing the BUFFERCOUNT. When writing data through the network, several items should be considered:

- Unless the application requires that records be written using unbuffered writes, enable buffered writes by a method described above.
- Especially with large files, increasing the BLOCKSIZE value increases the size of the block sent on the network and how often network data blocks get sent.
- Time the application when using different BLOCKSIZE values under similar conditions to find the optimal network block size.

Completion of a WRITE statement, even when not buffered, does not guarantee that the data has been written to disk; the operating system may delay the actual disk write. To ensure that the data has been written to disk, you can call the FLUSH routine. Because this can cause a significant slowdown of the application, FLUSH should be used only when absolutely needed.
**Linux® Only:** When writing records, be aware that I/O records are written to unified buffer cache (UBC) system buffers. To request that I/O records be written from program buffers to the UBC system buffers, use the FLUSH library routine. Be aware that calling FLUSH also discards read-ahead data in user buffer. For more information, see FLUSH in the *Intel® Fortran Libraries Reference*.

**Specify RECL**

The sum of the record length (RECL specifier in an OPEN statement) and its overhead is a multiple or divisor of the blocksize, which is device-specific. For example, if the BLOCKSIZE is 8192 then RECL might be 24576 (a multiple of 3) or 1024 (a divisor of 8).

The RECL value should fill blocks as close to capacity as possible (but not over capacity). Such values allow efficient moves, with each operation moving as much data as possible; the least amount of space in the block is wasted. Avoid using values larger than the block capacity, because they create very inefficient moves for the excess data only slightly filling a block (allocating extra memory for the buffer and writing partial blocks are inefficient).

The RECL value unit for formatted files is always 1-byte units. For unformatted files, the RECL unit is 4-byte units, unless you specify the -assume byterecl (Linux) or /assume:byterecl (Windows) option for the ASSUME specifier to request 1-byte units.

**Use the Optimal Record Type**

Unless a certain record type is needed for portability reasons, choose the most efficient type, as follows:

- For sequential files of a consistent record size, the fixed-length record type gives the best performance.
- For sequential unformatted files when records are not fixed in size, the variable-length record type gives the best performance, particularly for BACKSPACE operations.
- For sequential formatted files when records are not fixed in size, the Stream_LF record type gives the best performance.
Reading from a Redirected Standard Input File

Due to certain precautions that the Fortran run-time system takes to ensure the integrity of standard input, reads can be very slow when standard input is redirected from a file. For example, when you use a command such as myprogram.exe < myinput.data>, the data is read using the READ(*) or READ(5) statement, and performance is degraded. To avoid this problem, do one of the following:

• Explicitly open the file using the OPEN statement. For example: OPEN(5, STATUS='OLD', FILE='myinput.dat')

• Use an environment variable to specify the input file.

To take advantage of these methods, be sure your program does not rely on sharing the standard input file.

For more information on Intel Fortran data files and I/O, see Files, Devices, and I/O in the Building Applications; on OPEN statement specifiers and defaults, see Open Statement in the Intel® Fortran Language Reference.

Improving Run-time Efficiency

Use these source-coding guidelines to improve run-time performance. The amount of improvement in run-time performance is related to the number of times a statement is executed. For example, improving an arithmetic expression executed within a loop many times has the potential to improve performance, more than improving a similar expression executed once outside a loop.

Avoid Small Integer and Small Logical Data Items

Avoid using integer or logical data less than 32 bits. Accessing a 16-bit (or 8-bit) data type can make data access less efficient, especially on IA-64 architecture based systems.

To minimize data storage and memory cache misses with arrays, use 32-bit data rather than 64-bit data, unless you require the greater numeric range of 8-byte integers or the greater range and precision of double precision floating-point numbers.

Avoid Using Slow Arithmetic Operators

Before you modify source code to avoid slow arithmetic operators, be aware that optimizations convert many slow arithmetic operators to faster arithmetic operators. For example, the compiler optimizes the expression H=J**2 to be H=J*J.
Consider also whether replacing a slow arithmetic operator with a faster arithmetic operator will change the accuracy of the results or impact the maintainability (readability) of the source code.

Replacing slow arithmetic operators with faster ones should be reserved for critical code areas. The following list shows the Intel Fortran arithmetic operators, from fastest to slowest:

1. Addition (+), Subtraction (-), and Floating-point multiplication (*)
2. Integer multiplication (*)
3. Division (/)
4. Exponentiation (**)  

**Avoid Using EQUIVALENCE Statements**

Avoid using `EQUIVALENCE` statements. `EQUIVALENCE` statements can:

- Force unaligned data or cause data to span natural boundaries.
- Prevent certain optimizations, including:
  - Global data analysis under certain conditions; see the `-O2` (Linux*) or `/O2` (Windows*) option description for more information.
  - Implied-DO loop collapsing when the control variable is contained in an `EQUIVALENCE` statement

**Use Statement Functions and Internal Subprograms**

Whenever the Intel compiler has access to the use and definition of a subprogram during compilation, it may choose to inline the subprogram. Using statement functions and internal subprograms maximizes the number of subprogram references that will be inlined, especially when multiple source files are compiled together at optimization level `-O3` (Linux) or `/O3` (Windows).

For more information, see Efficient Compilation.

**Code DO Loops for Efficiency**

Minimize the arithmetic operations and other operations in a DO loop whenever possible. Moving unnecessary operations outside the loop will improve performance (for example, when the intermediate nonvarying values within the loop are not needed).
Using Fortran Intrinsics

Intel® Fortran supports all standard Fortran intrinsic procedures and provides Intel-specific intrinsic procedures to extend the language functionality. The Intel-specific intrinsic procedures are provided in libifcore.lib. For more details on these intrinsic procedures, see the Intel® Fortran Language Reference.

This topic provides an example of an Intel-extended intrinsic that is helpful in developing efficient applications on IA-32, Intel® 64, and IA-64 architectures.

CACHESIZE Intrinsic

The intrinsic CACHESIZE(n) returns the size in kilobytes of the cache at level n; one (1) represents the first level cache. Zero (0) is returned for a nonexistent cache level.

Use this intrinsic in any situation you would like to tailor algorithms for the cache hierarchy on the target processor. For example, an application may query the cache size and use the result to select block sizes in algorithms that operate on matrices.

Example

```fortran
subroutine foo (level)
   integer level
   if (cachesize(level) > threshold) then
      call big_bar()
   else
      call small_bar()
   end if
end subroutine
```

Understanding Run-time Performance

The information in this topic assumes that you are using a performance optimization methodology and have analyzed the application type you are optimizing.

After profiling your application to determine where best to spend your time, attempt to discover what optimizations and what limitations have been imposed by the compiler. Use the compiler reports to determine what to try next.
Depending on what you discover from the reports you may be able to help the compiler through options, directives, and slight code modifications to take advantage of key architectural features to achieve the best performance.

The compiler reports can describe what actions have been taken and what actions cannot be taken based on the assumptions made by the compiler. Experimenting with options and directives allows you to use an understanding of the assumptions and suggest a new optimization strategy or technique.

**Helping the Compiler**

You can help the compiler in some important ways:

- Read the appropriate reports to gain an understanding of what the compiler is doing for you and the assumptions the compiler has made with respect to your code.
- Use specific options, intrinsics, libraries, and directives to get the best performance from your application.

Use the Math Kernel Library (MKL) instead of user code, or calling F90 intrinsics instead of user code.

See [Applying Optimization Strategies](#) for other suggestions.

**Memory Aliasing For IA-64 Architectures**

Memory aliasing is the single largest issue affecting the optimizations in the Intel® compiler for IA-64 architecture based systems. Memory aliasing is writing to a given memory location with more than one pointer. The compiler is cautious to not optimize too aggressively in these cases; if the compiler optimizes too aggressively, unpredictable behavior can result (for example, incorrect results, abnormal termination, etc.).

Since the compiler usually optimizes on a module-by-module, function-by-function basis, the compiler does not have an overall perspective with respect to variable use for global variables or variables that are passed into a function; therefore, the compiler usually assumes that any pointers passed into a function are likely to be aliased. The compiler makes this assumption even for pointers you know are not aliased. This behavior means that perfectly safe loops do not get pipelined or vectorized, and performance suffers.

There are several ways to instruct the compiler that pointers are not aliased:

- Use a comprehensive compiler option, such as `-fno-alias` (Linux*) or `/Oa` (Windows*). These options instruct the compiler that no pointers in any module are aliased, placing the responsibility of program correctness directly with the developer.
• Use a less comprehensive option, like `-fnocallalias` (Linux) or `/Ow` (Windows). These options instruct the compiler that no pointers passed through function arguments are aliased.

Function arguments are a common example of potential aliasing that you can clarify for the compiler. You may know that the arguments passed to a function do not alias, but the compiler is forced to assume so. Using these options tells the compiler it is now safe to assume that these function arguments are not aliased. This option is still a somewhat bold statement to make, as it affects all functions in the module(s) compiled with the `-fnocallalias` (Linux) or `/Ow` (Windows) option.

• Use the IDVEP directive. Alternatively, you might use a directive that applies to a specified loop in a function. This is more precise than specifying an entire function. The directive asserts that, for a given loop, there are no vector dependencies. Essentially, this is the same as saying that no pointers are aliasing in a given loop.
Non-Unit Stride Memory Access

Another issue that can have considerable impact on performance is accessing memory in a non-Unit Stride fashion. This means that as your inner loop increments consecutively, you access memory from non-adjacent locations. For example, consider the following matrix multiplication code:

```fortran
Example
!
subroutine non_unit_stride_memory_access(a,b,c, NUM)
    implicit none
    integer :: i,j,k,NUM
    real :: a(NUM,NUM), b(NUM,NUM), c(NUM,NUM)
!
    loop before loop interchange
    do i=1,NUM
        do j=1,NUM
            do k=1,NUM
                c(j,i) = c(j,i) + a(j,k) * b(k,i)
            end do
        end do
    end do

end subroutine non_unit_stride_memory_access
```

Notice that \(c[i][j]\), and \(a[i][k]\) both access consecutive memory locations when the inner-most loops associated with the array are incremented. The \(b\) array however, with its loops with indexes \(k\) and \(j\), does not access Memory Unit Stride. When the loop reads \(b[k=0][j=0]\) and then the \(k\) loop increments by one to \(b[k=1][j=0]\), the loop has skipped over \(NUM\) memory locations having skipped \(b[k][1], b[k][2], \ldots, b[k][NUM]\).

Loop transformation (sometimes called loop interchange) helps to address this problem. While the compiler is capable of doing loop interchange automatically, it does not always recognize the opportunity.

The memory access pattern for the example code listed above is illustrated in the following figure:
Assume you modify the example code listed above by making the following changes to introduce loop interchange:

```
Example
subroutine unit_stride_memory_access(a,b,c, NUM)
  implicit none
  integer :: i,j,k,NUM
  real :: a(NUM,NUM), b(NUM,NUM), c(NUM,NUM)
! loop after interchange
  do i=1,NUM
    do k=1,NUM
      do j=1,NUM
        c(j,i) = c(j,i) + a(j,k) * b(k,i)
      end do
    end do
  end do
end subroutine unit_stride_memory_access
```

After the loop interchange the memory access pattern might look the following figure:

Understanding Data Alignment

Aligning data on boundaries can help performance. The Intel® compiler attempts to align data on boundaries for you. However, as in all areas of optimization, coding practices can either help or hinder the compiler and can lead to performance problems.

Always attempt to optimize using compiler options first.

To avoid performance problems you should keep the following guidelines in mind, which are separated by architecture:
IA-32, Intel® 64, and IA-64 architectures:

- Do not access or create data at large intervals that are separated by exactly $2^n$ (for example, 1 KB, 2 KB, 4 KB, 16 KB, 32 KB, 64 KB, 128 KB, 512 KB, 1 MB, 2 MB, 4 MB, 8 MB, etc.).
- Align data so that memory accesses does not cross cache lines (for example, 32 bytes, 64 bytes, 128 bytes).
- Use Application Binary Interface (ABI) for the Itanium® compiler to insure that ITP pointers are 16-byte aligned.

IA-32 and Intel® 64 architectures:

- Align data to correspond to the SIMD or Streaming SIMD Extension registers sizes.

IA-64 architecture:

- Avoid using packed structures.
- Avoid casting pointers of small data elements to pointers of large data elements.
- Do computations on unpacked data, then repack data if necessary, to correctly output the data.

In general, keeping data in cache has a better performance impact than keeping the data aligned. Try to use techniques that conform to the rules listed above.

See Setting Data Type and Alignment for more detailed information on aligning data.

Timing Your Application

You can start collecting information about your application performance by timing your application. More sophisticated and helpful data can be collected by using performance analysis tools.

Considerations on Timing Your Application

One of the performance indicators is your application timing. The following considerations apply to timing your application:

- Run program timings when other users are not active. Your timing results can be affected by one or more CPU-intensive processes also running while doing your timings.
- Try to run the program under the same conditions each time to provide the most accurate results, especially when comparing execution times of a previous version of the same program. Use the same system (processor model, amount of memory, version of the operating system, and so on) if possible.
If you do need to change systems, you should measure the time using the same version of
the program on both systems, so you know each system's effect on your timings.

For programs that run for less than a few seconds, run several timings to ensure that the
results are not misleading. Certain overhead functions like loading libraries might influence
short timings considerably.

If your program displays a lot of text, consider redirecting the output from the program.
Redirecting output from the program will change the times reported because of reduced
screen I/O.

Timings that show a large amount of system time may indicate a lot of time spent doing
I/O, which might be worth investigating.

For programs that run for less than a few seconds, run several timings to ensure that the
results are not misleading. Overhead functions like loading shared libraries might influence
short timings considerably.

Use the `time` command and specify the name of the executable program to provide the
following:

- The elapsed, real, or "wall clock" time, which will be greater than the total charged actual
CPU time.
- Charged actual CPU time, shown for both system and user execution. The total actual
CPU time is the sum of the actual user CPU time and actual system CPU time.

**Methods of Timing Your Application**

To perform application timings, use a version of the `TIME` command in a `.BAT` file (or the
function timing profiling option). You might consider modifying the program to call routines
within the program to measure execution time (possibly using conditionally compiled lines).

For example:

- Intel Fortran intrinsic procedures, such as `SECNDS`, `CPU_TIME`, `SYSTEM_CLOCK`, `TIME`, and
`DATE_AND_TIME`.
- Portability library routines, such as `DCLOCK`, `ETIME`, `SECNDS`, or `TIME`.

Whenever possible, perform detailed performance analysis on a system that closely resembles
the system(s) that will be used for actual application use.
Sample Timing

The following program template could be run by a .BAT file that executes the \texttt{TIME} command both before and after execution, to provide an approximate wall-clock time for the execution of the entire program. The Fortran intrinsic \texttt{CPU_TIME} can be used at selected points in the program to collect the CPU time between the start and end of the task to be timed.

\begin{verbatim}
REAL time_begin, time_end
...
CALL CPU_TIME ( time_begin )
!
!task to be timed
!
CALL CPU_TIME ( time_end )
PRINT *, 'Time of operation was ', &
time_end - time_begin, ' seconds'
\end{verbatim}

Considerations for Linux*

In the following example timings, the sample program being timed displays the following line:

\begin{verbatim}
Bourne* shell example
Average of all the numbers is: 4368488960.000000
\end{verbatim}
Using the Bourne* shell, the following program timing reports that the program uses 1.19
seconds of total actual CPU time (0.61 seconds in actual CPU time for user program use and
0.58 seconds of actual CPU time for system use) and 2.46 seconds of elapsed time:

**Bourne* shell example**

```
$ time a.out
Average of all the numbers is:  4368488960.000000
real   0m2.46s
user   0m0.61s
sys    0m0.58s
```

Using the C shell, the following program timing reports 1.19 seconds of total actual CPU time
(0.61 seconds in actual CPU time for user program use and 0.58 seconds of actual CPU time
for system use), about 4 seconds (0:04) of elapsed time, the use of 28% of available CPU time,
and other information:

**C shell l example**

```
% time a.out
Average of all the numbers is:  4368488960.000000
0.61u 0.58s 0:04 28% 78+424k 9+5io 0pf+0w
```

Using the bash shell, the following program timing reports that the program uses 1.19 seconds
of total actual CPU time (0.61 seconds in actual CPU time for user program use and 0.58 seconds
of actual CPU time for system use) and 2.46 seconds of elapsed time:

**bash shell l example**

```
[user@system user]$ time ./a.out
Average of all the numbers is:  4368488960.000000
elapsed 0m2.46s
user 0m0.61s
sys 0m0.58s
```
Timings that indicate a large amount of system time is being used may suggest excessive I/O, a condition worth investigating.

If your program displays a lot of text, you can redirect the output from the program on the time command line. Redirecting output from the program will change the times reported because of reduced screen I/O.

For more information, see time(1).

In addition to the time command, you might consider modifying the program to call routines within the program to measure execution time. For example, use the Intel intrinsic procedures, such as SECNDS, DCLOCK, CPU_TIME, SYSTEM_CLOCK, TIME, and DATE_AND_TIME.

Applying Optimization Strategies

The compiler may or may not apply the following optimizations to your loop: Interchange, Unrolling, Cache Blocking, and LoadPair. These transformations are discussed in the following sections, including how to transform loops manually and how to control them with directives or internal options.

Loop Interchange

Loop Interchange is a nested loop transformation applied by High-level Optimization (HLO) that swaps the order of execution of two nested loops. Typically, the transformation is performed to provide sequential Unit Stride access to array elements used inside the loop to improve cache locality. The compiler -O3 (Linux* and Mac OS* X) or /O3 (Windows*) optimization looks for opportunities to apply loop interchange for you.
The following is an example of a loop interchange

Example

```fortran
subroutine loop_interchange(a,b,c, NUM)
implicit none
integer :: i,j,k,NUM
real :: a(NUM,NUM), b(NUM,NUM), c(NUM,NUM)
! loop before loop interchange
do i=1,NUM
  do j=1,NUM
    do k=1,NUM
      c(j,i) = c(j,i) + a(j,k) * b(k,i)
    end do
  end do
end do
! loop after interchange
do i=1,NUM
  do k=1,NUM
    do j=1,NUM
      c(j,i) = c(j,i) + a(j,k) * b(k,i)
    end do
  end do
end do
end subroutine loop_interchange
```
Unrolling

Loop unrolling is a loop transformation generally used by HLO that can take better advantage of Instruction-Level Parallelism (ILP), keeping as many functional units busy doing useful work as possible during single loop iteration. In loop unrolling, you add more work to the inside of the loop while doing fewer loop iterations in exchange.

Example

```fortran
subroutine loop_unroll_before(a,b,c,N,M)
  implicit none
  integer :: i,j,N,M
  real :: a(N,M), b(N,M), c(N,M)
  N=1025
  M=5
  do i=1,N
    do j=1,M
      a(j,i) = b(j,i) + c(j,i)
    end do
  end do
end subroutine loop_unroll_before
```

Example

```fortran
subroutine loop_unroll_after(a,b,c,N,M)
  implicit none
  integer :: i,j,K,N,M
  real :: a(N,M), b(N,M), c(N,M)
  N=1025
  M=5
  K=MOD(N,4) !K= N MOD 4
  ! main part of loop
```
Example

```fortran
do i=1,N-K,4
    do j=1,M
        a(j,i) = b(j,i) + c(j,i)
        a(j,i+1) = b(j,i+1) + c(j,i+1)
        a(j,i+2) = b(j,i+2) + c(j,i+2)
        a(j,i+3) = b(j,i+3) + c(j,i+3)
    end do
end do
! post conditioning part of loop
do i= N-K+2, N, 4
    do j=1,M
        a(j,i) = b(j,i) + c(j,i)
    end do
end do
end subroutine loop_unroll_after
```

Post conditioning is preferred over pre-conditioning because post conditioning will preserve the data alignment and avoid the cost of memory alignment access penalties.

**Cache Blocking**

Cache blocking involves structuring data blocks so that they conveniently fit into a portion of the L1 or L2 cache. By controlling data cache locality, an application can minimize performance delays due to memory bus access. The application controls the behavior by dividing a large array into smaller blocks of memory so a thread can make repeated accesses to the data while the data is still in cache.

For example, image processing and video applications are well suited to cache blocking techniques because an image can be processed on smaller portions of the total image or video frame. Compilers often use the same technique, by grouping related blocks of instructions close together so they execute from the L2 cache.
The effectiveness of the cache blocking technique depends on data block size, processor cache size, and the number of times the data is reused. Cache sizes vary based on processor. An application can detect the data cache size using the CPUID instruction and dynamically adjust cache blocking tile sizes to maximize performance. As a general rule, cache block sizes should target approximately one-half to three-quarters the size of the physical cache. For systems that are Hyper-Threading Technology (HT Technology) enabled target one-quarter to one-half the physical cache size. Designing for Hyper-Threading Technology
Cache blocking is applied in HLO and is used on large arrays where the arrays cannot all fit into cache simultaneously. This method is one way of pulling a subset of data into cache (in a small region), and using this cached data as effectively as possible before the data is replaced by new data from memory.

**Example**

```fortran
subroutine cache_blocking_before(a,b,N)
    implicit none
    integer :: i,j,k,N
    real :: a(N,N,N), b(N,N,N), c(N,N,N)
    N=1000
    do i = 1, N
        do j = 1, N
            do k = 1, N
                a(i,j,k) = a(i,j,k) + b(i,j,k)
            end do
        end do
    end do
end subroutine cache_blocking_before

subroutine cache_blocking_after(a,b,N)
    implicit none
    integer :: i,j,k,u,v,N
    real :: a(N,N,N), b(N,N,N), c(N,N,N)
    N=1000
    do v = 1, N, 20
        do u = 1, N, 20
            do k = v, v+19
                do j = u, u+19
                    do i = 1, N
                        a(i,j,k) = a(i,j,k) + b(i,j,k)
                    end do
                end do
            end do
        end do
    end do
end subroutine cache_blocking_after
```
The cache block size is set to 20. The goal is to read in a block of cache, do every bit of computing we can with the data in this cache, then load a new block of data into cache. There are 20 elements of $A$ and 20 elements of $B$ in cache at the same time and you should do as much work with this data as you can before you increment to the next cache block.

Blocking factors will be different for different architectures. Determine the blocking factors experimentally. For example, different blocking factors would be required for single precision versus double precision. Typically, the overall impact to performance can be significant.
Loop Distribution

Loop distribution is a high-level loop transformation that splits a large loop into two smaller loops. It can be useful in cases where optimizations like software-pipelining (SWP) or vectorization cannot take place due to excessive register usage. By splitting a loop into smaller segments, it may be possible to get each smaller loop or at least one of the smaller loops to SWP or vectorize. An example is as follows:

```
Example

subroutine loop_distribution_before(a,b,c,x,y,z,N)
  implicit none
  integer :: i,N
  real :: a(N), b(N), c(N), x(N), y(N), z(N)
  N=1024
  do i = 1, N
    a(i) = a(i) + i
    b(i) = b(i) + i
    c(i) = c(i) + i
    x(i) = x(i) + i
    y(i) = y(i) + i
    z(i) = z(i) + i
  end do
end subroutine loop_distribution_before

subroutine loop_distribution_after(a,b,c,x,y,z,N)
  implicit none
  integer :: i,N
  real :: a(N), b(N), c(N), x(N), y(N), z(N)
  N=1024
  do i = 1, N
    a(i) = a(i) + i
    b(i) = b(i) + i
```
There are directives to suggest distributing loops to the compiler as follows:

```
Example

    c(i) = c(i) + i
    end do
    do i = 1, N
        x(i) = x(i) + i
        y(i) = y(i) + i
        z(i) = z(i) + i
    end do
end subroutine loop_distribution_after
```

```
Example

    !DEC$ distribute point
```

Placed outside a loop, the compiler will attempt to distribute the loop based on an internal heuristic. The following is an example of using the pragma outside the loop:

**Example**

```fortran
subroutine loop_distribution_pragma1(a,b,c,x,y,z,N)
    implicit none
    integer :: i,N
    real :: a(N), b(N), c(N), x(N), y(N), z(N)
    N=1024
    !DEC$ distribute point
    do i = 1, N
        a(i) = a(i) + i
        b(i) = b(i) + i
        c(i) = c(i) + i
        x(i) = x(i) + i
        y(i) = y(i) + i
        z(i) = z(i) + i
    end do
end subroutine loop_distribution_pragma1
```
Placed within a loop, the compiler will attempt to distribute the loop at that point. All loop-carried dependencies will be ignored. The following example uses the directive within a loop to precisely indicate where the split should take place:

**Example**

```fortran
subroutine loop_distribution_pragma2(a,b,c,x,y,z,N)
  implicit none
  integer :: i,N
  real :: a(N), b(N), c(N), x(N), y(N), z(N)
  N=1024
  do i = 1, N
    a(i) = a(i) + i
    b(i) = b(i) + i
    c(i) = c(i) + i
    !DEC$ distribute point
    x(i) = x(i) + i
    y(i) = y(i) + i
    z(i) = z(i) + i
  end do
end subroutine loop_distribution_pragma2
```

**Load Pair (Itanium® Compiler)**

Load pairs (ldfp) are instructions that load two contiguous single or double precision values from memory in one move. Load pairs can significantly improve performance.

**Manual Loop Transformations**

There might be cases where these manual transformations are called acceptable or even preferred. As a general rule, you should let the compiler transform loops for you. Manually transform loops as a last resort; use this strategy only in cases where you are attempting to gain performance increases.
Manual loop transformations have many disadvantages, which include the following:

- Application code becomes harder to maintain over time.
- New compiler features can cause you to lose any optimization you gain by manually transforming the loop.
- Architectural requirements might restrict your code to a specific architecture unintentionally.

The HLO report can give you an idea of what loop transformations have been applied by the compiler.

Experimentation is a critical component in manually transforming loops. You might try to apply a loop transformation that the compiler ignored. Sometimes, it is beneficial to apply a manual loop transformation that the compiler has already applied with `-O3` (Linux) or `/O3` (Windows).

**Optimizing the Compilation Process**

**Optimizing the Compilation Process Overview**

This section describes the Intel® compiler options that can optimize the compilation process. By default, the compiler converts source code directly to an executable file. Appropriate options enable you not only to control the process and obtain desired output file produced by the compiler, but also make the compilation itself more efficient.

A group of options monitors the outcome of Intel compiler-generated code without interfering with the way your program runs. These options control some computation aspects, such as allocating the stack memory, setting or modifying variable settings, and defining the use of some registers.

The options in this section provide you with the following capabilities of efficient compilation:

- Compiling efficiently
- Using default compiler optimizations
- Automatic allocation of variables and stacks
- Converting little-endian to big-endian
- Symbol visibility attribute options

**Efficient Compilation**

Efficient compilation contributes to performance improvement. Before you analyze your program for performance improvement, and improve program performance, you should think of efficient compilation itself.
Based on the analysis of your application, you can decide which compiler optimizations and command-line options can improve the run-time performance of your application.

**Efficient Compilation Techniques**

The efficient compilation techniques can be used during the earlier stages and later stages of program development. During the earlier stages of program development, you can use incremental compilation without optimization. For example:

**Linux* and Mac OS* X**

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| ifort -c -g -O0 sub2.f90  
ifort -c -g -O0 sub3.f90  
ifort -o main -g -O0 main.f90 sub2.o sub3.o |

The above commands turn off all compiler default optimizations, for example, -O2 (Linux* and Mac OS* X) or /O2 (Windows*), with -O0 (Linux and Mac OS X) or /Od (Windows). You can use the -g (Linux) or /Zi or /debug:full (Windows) option to generate symbolic debugging information and line numbers in the object code for all routines in the program for use by a source-level debugger. The main file created in the third command above contains symbolic debugging information as well.

During the later stages of program development, you should specify multiple source files together and use an optimization level of at least -O2 (Linux and Mac OS X) or /O2 (Windows) to allow more optimizations to occur. For instance, the following command compiles all three source files together using the default level of optimization:

**Linux and Mac OS X**

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>ifort -o main main.f90 sub2.f90 sub3.f90</td>
</tr>
</tbody>
</table>

Compiling multiple source files lets the compiler examine more code for possible optimizations, which results in:

- Inlining more procedures
- More complete data flow analysis
- Reducing the number of external references to be resolved during linking
For very large programs, compiling all source files together may not be practical. In such instances, consider compiling source files containing related routines together using multiple ifort commands, rather than compiling source files individually.

**Stacks: Automatic Allocation and Checking**

The options in this group enable you to control the computation of stacks and variables in the compiler generated code.

**Automatic Allocation of Variables**

- **-automatic** (Linux* and Mac OS* X) and **/automatic** (Windows*)

These options specify that locally declared variables are allocated to the run-time stack rather than static storage. If variables defined in a procedure do not have the SAVE or ALLOCATABLE attribute, they are allocated to the stack. It does not affect variables that appear in an EQUIVALENCE or SAVE statement, or those that are in COMMON.

- **-automatic** (Linux and Mac OS X) or **/automatic** (Windows) may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly. Variables that need to retain their values across routine calls should appear in a SAVE statement.

**NOTE.** Linux: If you specify **-recursive** or **-openmp**, the default is **-auto**.

Windows: The Windows NT* system imposes a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with **/Qauto** because arrays are allocated on the stack along with scalars.

- **-auto-scalar** (Linux and Mac OS X) or **/Qauto-scalar** (Windows)

These options cause allocation of local scalar variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL to the stack. This option does not affect variables that appear in an EQUIVALENCE or SAVE statement, or those that are in COMMON.

The **-auto-scalar** (Linux and Mac OS X) or **/Qauto-scalar** (Windows) option may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly. Variables that need to retain their values across subroutine calls should appear in a SAVE statement. This option is similar to **-auto** (Linux and Mac OS X) and **/Qauto** (Windows) which
causes all local variables to be allocated on the stack. The difference is that \texttt{-auto-scalar} (Linux and Mac OS X) or \texttt{/Qauto-scalar} (Windows) allocates only scalar variables of the stated above intrinsic types to the stack.

\textbf{NOTE.} Windows: Windows NT\textsuperscript{*} imposes a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with \texttt{/Qauto} because arrays are allocated on the stack along with scalars. However, with \texttt{/Qauto-scalar}, you would have to have more than 32K bytes of local scalar variables before you incurred the performance penalty.

\texttt{-auto-scalar} (Linux and Mac OS X) or \texttt{/Qauto-scalar} (Windows) enables the compiler to make better choices about which variables should be kept in registers during program execution.

\texttt{-save, -zero[-]} (Linux and Mac OS X) or \texttt{/Qsave, /Qzero[-]} (Windows)

The \texttt{-save} (Linux and Mac OS X) or \texttt{/Qsave} (Windows) option is opposite of \texttt{-auto} (Linux) or \texttt{/Qauto} (Windows). The \texttt{-save} (Linux and Mac OS X) or \texttt{/Qsave} (Windows) option saves all variables in static allocation except local variables within a recursive routine.

If a routine is invoked more than once, this option forces the local variables to retain their values from the last invocation. The \texttt{save} option ensures that the final results on the exit of the routine is saved on memory and can be reused at the next occurrence of that routine. This may cause some performance degradation as it causes more frequent rounding of the results.

\textbf{NOTE.} Linux and Mac OS X: \texttt{-save} is the same as \texttt{-noauto}.

Windows: \texttt{/Qsave} is the same as \texttt{save}, and \texttt{/noautomatic}.

When the compiler optimizes the code, the results are stored in registers.

The \texttt{-zero[-]} (Linux and Mac OS X) or \texttt{/Qzero[-]} (Windows) option initializes to zero all local scalar variables of intrinsic type \texttt{INTEGER}, \texttt{REAL}, \texttt{COMPLEX}, or \texttt{LOGICAL}, which are saved and not initialized yet. Used in conjunction with \texttt{SAVE}.

**Summary**

There are three options for allocating variables: \texttt{-save} (Linux and Mac OS X) or \texttt{/Qsave} (Windows), \texttt{-auto} (Linux) or \texttt{/Qauto} (Windows) and \texttt{-auto-scalar} (Linux) or \texttt{/Qauto-scalar} (Windows). Only one of these three can be specified.

The correlation among them is as follows:
• **-save** (Linux and Mac OS X) or **/Qsave** (Windows) disables **-auto** (Linux and Mac OS X) or **/Qauto** (Windows), sets **-noauto** (Linux and Mac OS X) or **/noautomatic** (Windows), and allocates all variables not marked **AUTOMATIC** to static memory.

• **-auto** (Linux and Mac OS X) or **/Qauto** (Windows) disables **-save** (Linux and Mac OS X) or **/Qsave** (Windows), sets **-nosave** (Linux and Mac OS X) or **/automatic** (Windows) and allocates all variables, scalars and arrays of all types, not marked **SAVE** to the stack.

• **-auto-scalar** (Linux and Mac OS X) or **/Qauto-scalar** (Windows) makes local scalars of intrinsic types **INTEGER**, **REAL**, **COMPLEX**, and **LOGICAL** automatic. Additionally, this is the default. There is no **-noauto-scalar** (Linux and Mac OS X) or **/Qauto-scalar-** (Windows); however, **-recursive** or **-openmp** (Linux and Mac OS X) or **/recursive** or **/Openmp** (Windows) disables **-auto-scalar** (Linux and Mac OS X) or **/Qauto-scalar** (Windows) and makes **-auto** (Linux and Mac OS X) or **/Qauto** (Windows) the default.

**Checking and Setting Space**

The following options perform checking and setting space for stacks (these options are supported on Windows only):

• The **/Gs0** option enables stack-checking for all functions.

• The **/Gs**n option checks by default the stack space allocated for functions with more than 4KB.

• The **/Fn** option sets the stack reserve amount for the program. The **/Fn** option passes **/stack:**n to the linker.

**Aliases**

The **-common-args** (Linux and Mac OS X) or **/Qcommon-args** (Windows) option assumes that the by-reference subprogram arguments may have aliases of one another.

It is recommended that you use the **-assume dummy_aliases** (Linux and Mac OS X) or **/assume:dummy_aliases** (Windows) option instead of the **common-args** option.

For more information about using the preferred option, see the following topic:

• **-assume compiler option**
Preventing CRAY* Pointer Aliasing

Option `-safe-cray-ptr` (Linux and Mac OS X) or `/Qsafe-cray-ptr` (Windows) specifies that the CRAY* pointers do not alias with other variables. Consider the following example.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| pointer {pb, b}  
| pb = getstorage()  
| do i = 1, n  
|  
| b(i) = a(i) + 1  
| enddo |

When the option is not specified, the compiler assumes that b and a are aliased. To prevent such an assumption, specify this option, and the compiler will treat $b(i)$ and $a(i)$ as independent of each other.

However, if the variables are intended to be aliased with CRAY pointers, using the `-safe-cray-ptr` (Linux and Mac OS X) or `/Qsafe-cray-ptr` (Windows) option produces incorrect result. For the code example below, the option should not be used.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| pb = loc(a(2))  
| do i=1, n  
|  
| b(i) = a(i) +1  
| enddo |

Cross Platform

For example, an object of type real cannot be accessed as an integer. You should see the ANSI standard for the complete set of rules.

The option directs the compiler to assume the following:

- Arrays are not accessed out of arrays' bounds.
- Pointers are not cast to non-pointer types and vice-versa.
References to objects of two different scalar types cannot alias. For example, an object of type integer cannot alias with an object of type real or an object of type real cannot alias with an object of type double precision.

If your program satisfies the above conditions, setting this option will help the compiler better optimize the program. However, if your program may not satisfy one of the above conditions, the option must be disabled, as it can lead the compiler to generate incorrect code.

For more information, see the following topic:

• 

-ansi-alias compiler option

Little-endian-to-Big-endian Conversion (IA-32 Architecture)

The Intel® compiler can write unformatted sequential files in big-endian format and can also read files produced in big-endian format by using the little-endian-to-big-endian conversion feature.

On processors based on IA-32 or IA-64 architectures, Intel Fortran handles internal data in little-endian format. The little-endian-to-big-endian conversion feature is intended for Fortran unformatted input/output operations in unformatted sequential files. The feature enables the following:

• Processing of the files developed on processors that accept big-endian data format
• Producing big-endian files for such processors on little-endian systems.

The little-endian-to-big-endian conversion is accomplished by the following operations:

• The WRITE operation converts little-endian format to big-endian format.
• The READ operation converts big-endian format to little-endian format.

The feature enables the conversion of variables and arrays (or array subscripts) of basic data types. Derived data types are not supported.

Little-to-Big Endian Conversion Environment Variable

In order to use the little-endian-to-big-endian conversion feature, specify the numbers of the units to be used for conversion purposes by setting the _UFMTENDIAN environment variable. Then, the READ/WRITE statements that use these unit numbers, will perform relevant conversions. Other READ/WRITE statements will work in the usual way.

In the general case, the variable consists of two parts divided by a semicolon. No spaces are allowed inside the _UFMTENDIAN value. The variable has the following syntax:
Example

\[ F_{U\text{FMTENDIAN}}=\text{MODE} \ | \ [\text{MODE};] \ \text{EXCEPTION} \]

where the following conditions are true:

<table>
<thead>
<tr>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MODE = big</td>
</tr>
<tr>
<td>EXCEPTION = big:ULIST</td>
</tr>
<tr>
<td>ULIST = U</td>
</tr>
<tr>
<td>U = decimal</td>
</tr>
</tbody>
</table>

and the following conditions apply:

- **MODE** defines current format of data, represented in the files; it can be omitted.
  - The keyword *little* means that the data have little endian format and will not be converted. This keyword is a default.
  - The keyword *big* means that the data have big endian format and will be converted. This keyword may be omitted together with the colon.

- **EXCEPTION** is intended to define the list of exclusions for **MODE**; it can be omitted. **EXCEPTION** keyword (*little* or *big*) defines data format in the files that are connected to the units from the **EXCEPTION** list. This value overrides **MODE** value for the units listed.

- Each list member **U** is a simple unit number or a number of units. The number of list members is limited to 64.
  - **decimal** is a non-negative decimal number less than \(2^{32}\).

Converted data should have basic data types, or arrays of basic data types. Derived data types are disabled.

Command lines for variable setting with different shells:

<table>
<thead>
<tr>
<th>Shell</th>
<th>Command Line</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sh</td>
<td>export ( F_{U\text{FMTENDIAN}}=\text{MODE};\ \text{EXCEPTION} )</td>
</tr>
<tr>
<td>Csh</td>
<td>setenv ( F_{U\text{FMTENDIAN}} \ \text{MODE};\ \text{EXCEPTION} )</td>
</tr>
</tbody>
</table>
Another Possible Environment Variable Setting

The environment variable can also have the following syntax:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_UFMENDIAN=u[,u] . . .</td>
</tr>
</tbody>
</table>

Command lines for the variable setting with different shells:

<table>
<thead>
<tr>
<th>Shell</th>
<th>Command Line</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sh</td>
<td>export F_UFMENDIAN=u[,u] . . .</td>
</tr>
<tr>
<td>Csh</td>
<td>setenv F_UFMENDIAN u[,u] . . .</td>
</tr>
</tbody>
</table>

See error messages that may be issued during the little-endian to big-endian conversion. They are all fatal. You should contact Intel if such errors occur.

Usage Examples

The following usage examples illustrate the concepts detailed above.

<table>
<thead>
<tr>
<th>Example 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_UFMENDIAN=big</td>
</tr>
</tbody>
</table>

All input/output operations perform conversion from big-endian to little-endian on READ and from little-endian to big-endian on WRITE.

<table>
<thead>
<tr>
<th>Example 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_UFMENDIAN=&quot;little;big:10,20&quot;</td>
</tr>
<tr>
<td>or</td>
</tr>
<tr>
<td>F_UFMENDIAN=big:10,20</td>
</tr>
<tr>
<td>or</td>
</tr>
</tbody>
</table>
Example 2

F_UFMTENDIAN=10,20

In this case, only on unit numbers 10 and 20 the input/output operations perform big-little endian conversion.

Example 3

F_UFMTENDIAN="big;little:8"

In this case, on unit number 8 no conversion operation occurs. On all other units, the input/output operations perform big-little endian conversion.

Example 4

4. F_UFMTENDIAN=10-20

Define 10, 11, 12...19, 20 units for conversion purposes; on these units, the input/output operations perform big-little endian conversion.

Assume you set F_UFMTENDIAN=10,100 and run the following program.

Example 5

integer*4   cc4
integer*8   cc8
integer*4   c4
integer*8   c8

c4 = 456

c8 = 789
### Example 5

```fortran
C prepare a little endian representation of data
open(11,file='lit.tmp',form='unformatted')
write(11) c8
write(11) c4
close(11)
C prepare a big endian representation of data
open(10,file='big.tmp',form='unformatted')
write(10) c8
write(10) c4
close(10)
C read big endian data and operate with them on
C little endian machine.
open(100,file='big.tmp',form='unformatted')
read(100) cc8
read(100) cc4
C Any operation with data, which have been read
C
C...
close(100)
stop
end
```

You can compare `lit.tmp` and `big.tmp` files to see the difference of the byte order in these files.

**Linux* Systems Only**

On Linux* systems you can use the `od` utility to compare the files.
Example output

```
> od -t x4 lit.tmp
0000000 00000008 00000315 00000000 00000008
0000020 00000004 0000001c8 00000004
0000034
> od -t x4 big.tmp
0000000 08000000 00000000 15030000 08000000
0000020 04000000 c8010000 04000000
0000034
```

You can see that the byte order is different in these files. If `info` and `od` are installed on your Linux system, enter `info od` at the prompt to get more information about the utility.

**Symbol Visibility Attribute Options (Linux* and Mac OS* X)**

Applications that do not require symbol preemption or position-independent code can obtain a performance benefit by taking advantage of the generic ABI visibility attributes.

**Global Symbols and Visibility Attributes**

A global symbol is a symbol that is visible outside the compilation unit in which it is declared (compilation unit is a single-source file with the associated include files). Each global symbol definition or reference in a compilation unit has a visibility attribute that controls how it may be referenced from outside the component in which it is defined.

The values for visibility are defined and described in the following topic:

- `-fvisibility` compiler option

**NOTE.** Visibility applies to both references and definitions. A symbol reference's visibility attribute is an assertion that the corresponding definition will have that visibility.
Symbol Preemption and Optimization

Sometimes programmers need to use some of the functions or data items from a shareable object, but at the same time, they need to replace other items with definitions of their own. For example, an application may need to use the standard run-time library shareable object, libc.so, but to use its own definitions of the heap management routines malloc and free.

**NOTE.** In this case it is important that calls to malloc and free within libc.so use the user's definition of the routines and not the definitions in libc.so. The user's definition should then override, or preempt, the definition within the shareable object.

This functionality of redefining the items in shareable objects is called symbol preemption. When the run-time loader loads a component, all symbols within the component that have default visibility are subject to preemption by symbols of the same name in components that are already loaded. Note that since the main program image is always loaded first, none of the symbols it defines will be preempted (redefined).

The possibility of symbol preemption inhibits many valuable compiler optimizations because symbols with default visibility are not bound to a memory address until run-time. For example, calls to a routine with default visibility cannot be inlined because the routine might be preempted if the compilation unit is linked into a shareable object. A preemptable data symbol cannot be accessed using GP-relative addressing because the name may be bound to a symbol in a different component; and the GP-relative address is not known at compile time.

Symbol preemption is a rarely used feature and has negative consequences for compiler optimization. For this reason, by default the compiler treats all global symbol definitions as non-preemptable (protected visibility). Global references to symbols defined in another compilation unit are assumed by default to be preemptable (default visibility). In those rare cases where all global definitions as well as references need to be preemptable, you can override this default.

Specifying Symbol Visibility Explicitly

The Intel® compiler has visibility attribute options that provide command-line control of the visibility attributes in addition to a source syntax to set the complete range of these attributes.

The options ensure immediate access to the feature without depending on header file modifications. The visibility options cause all global symbols to get the visibility specified by the option. There are two variety of options to specify symbol visibility explicitly.
The first form specifies the default visibility for global symbols. The second form specifies the visibility for symbols that are in a file (this form overrides the first form).

**Specifying Visibility without the Symbol File**

This option sets the visibility for symbols not specified in a visibility list file and that do not have `VISIBILITY` attribute in their declaration. If no symbol file option is specified, all symbols will get the specified attribute. Command line example:

```
ifort -fvisibility=protected a.f
```

You can set the default visibility for symbols using one of the following command line options:

```
-fvisibility=extern
-fvisibility=default
-fvisibility=protected
-fvisibility=hidden
-fvisibility=internal
```

**Data Alignment Options**

These options control how the Intel® compiler align data items. Refer to Compiler Options for more information on using these alignment-related options.

</tr>
</thead>
</table>
| -fp-model<br>-fp-speculation<br>-prec-div, -no-prec-div | /fp<br>/Qfp-speculation<br>/Qprec-div,<br>/Qprec-div- | Specifies semantics used in floating-point calculations. Values are precise, fast [1/2], strict, source, double, extended, [no-]except (Linux* and MacOS* X) and except [-] (Windows*).

- -fp-model compiler option

- -fp-speculation compiler option

- Attempts to use slower but more accurate implementation of floating-point divide. Use this option to disable the divide optimizations in cases where it is important to maintain the full range and precision for floating-point division. Using this option results in greater accuracy with some loss of performance.

Specifying -no-prec-div (Linux* and Mac OS* X) or /Qprec-div- (Windows*) enable the divide-to-reciprocal multiply optimization; these results are slightly less precise than full IEEE division results.

</tbody>
</table>
Programming Tradeoffs in Floating-point Applications

In general, the programming objectives for floating-point applications fall into the following categories:

- **Accuracy**: The application produces results that are close to the correct result.
- **Reproducibility and portability**: The application produces consistent results across different runs, different sets of build options, different compilers, different platforms, and different architectures.
- **Performance**: The application produces fast, efficient code.

Based on the goal of an application, you will need to make tradeoffs among these objectives. For example, if you are developing a 3D graphics engine, then performance may be the most important factor to consider, and reproducibility and accuracy may be your secondary concerns.

The Intel® Compiler provides appropriate compiler options, such as the `-fp-model` (Linux* and Mac OS* X operating systems) or `/fp` (Windows* operating system) option, that allow you to tune your applications based on specific objectives. The compiler optimizes and generates code differently when you specify different compiler options. Take the following code as an example:

```fortran
REAL(4):: t0, t1, t2
...
  t0=t1+t2+4.0+0.1
```

If you specify the `-fp-model extended` (Linux* and Mac OS* X) or `/fp:extended` (Windows*) option in favor of accuracy, the compiler generates the following assembly code:

```assembly
fld DWORD PTR _t1
fadd DWORD PTR _t2
fadd DWORD PTR _Cnst4.0
fadd DWORD PTR _Cnst0.1
fstp DWORD PTR _t0
```

The above code maximizes accuracy because it utilizes the highest mantissa precision available on the target platform. However, the code might suffer in performance due to the overhead of managing the x87 stack and it might yield results that cannot be reproduced on other platforms that do not have an equivalent extended precision type.
If you specify the `-fp-model source` (Linux* and Mac OS* X) or `/fp:source` (Windows*) option in favor of reproducibility and portability, the compiler generates the following assembly code:

```assembly
movss  xmm0, DWORD PTR _t1
addss  xmm0, DWORD PTR _t2
addss  xmm0, DWORD PTR _Cnst4.0
addss  xmm0, DWORD PTR _Cnst0.1
movss  DWORD PTR _t0, xmm0
```

The above code maximizes portability by preserving the original order of the computation and by using the well-defined IEEE single-precision type for all computations. It is not as accurate as the previous implementation because the intermediate rounding error is greater compared to extended precision. And it is not the highest performance implementation because it does not take advantage of the opportunity to precompute $4.0 + 0.1$.

If you specify the `-fp-model fast` (Linux* and Mac OS* X) or `/fp:fast` (Windows*) option in favor of performance, the compiler generates the following assembly code:

```assembly
movss  xmm0, DWORD PTR _Cnst4.1
addss  xmm0, DWORD PTR _t1
addss  xmm0, DWORD PTR _t2
movss  DWORD PTR _t0, xmm0
```

The above code maximizes performance by using Intel® SSE instructions and precomputing $4.0 + 0.1$. It is not as accurate as the first implementation, again due to greater intermediate rounding error. It will not provide reproducible results like the second implementation because it must reorder the addition in order to precompute $4.0 + 0.1$, and you cannot expect that all compilers, on all platforms, at all optimization levels will reorder the addition in the same way.

For most other applications, the considerations may be more complicated. You should select appropriate compiler options by carefully balancing your programming objectives and making tradeoffs among these objectives.

**Floating-point Optimizations**

Application performance is an important goal of the Intel® Compilers, even at default optimization levels. A number of optimizations involve transformations that might affect the floating-point behavior of the application, such as evaluation of constant expressions at compile time, hoisting
invariant expressions out of loops, or changes in the order of evaluation of expressions. These optimizations usually help the compiler to produce the most efficient code possible. However, the optimizations might be contrary to the floating-point requirements of the application.

Some optimizations are not consistent with strict interpretation of the ANSI or ISO standards for Fortran. Such optimizations can cause differences in rounding and small variations in floating-point results that may be more or less accurate than the ANSI-conformant result.

Intel Compilers provide the `-fp-model` (Linux* and Mac OS* X) or `/fp` (Windows*) option, which allows you to control the optimizations performed when you build an application. The option allows you to specify the compiler rules for:

- **Value safety**: Whether the compiler may perform transformations that could affect the result. For example, in the SAFE mode, the compiler won't transform \( x/x \) to 1.0 because the value of \( x \) at runtime might be a zero or a NaN. The UNSAFE mode is the default.
- **Floating-point expression evaluation**: How the compiler should handle the rounding of intermediate expressions.
- **Floating-point contractions**: Whether the compiler should generate fused multiply-add (FMA) instructions on processors based on the IA-64 architecture. When enabled, the compiler may generate FMA instructions for combining multiply and add operations; when disabled, the compiler must generate separate multiply and add instructions with intermediate rounding.
- **Floating-point environment access**: Whether the compiler must account for the possibility that the program might access the floating-point environment, either by changing the default floating-point control settings or by reading the floating-point status flags. This is disabled by default. You can use the `-fp-model:strict` (Linux and Mac OS X) `/fp:strict` (Windows) option to enable it.
- **Precise floating-point exceptions**: Whether the compiler should account for the possibility that floating-point operations might produce an exception. This is disabled by default. You can use `-fp-model:strict` (Linux and Mac OS X) or `/fp:strict` (Windows); or `-fp-model:except` (Linux and Mac OS X) or `/fp:except` (Windows) to enable it.

The following table describes the impact of different keywords of the option on compiler rules and optimizations:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value Safety</th>
<th>Floating-Point Expression Evaluation</th>
<th>Floating-Point Contractions</th>
<th>Floating-Point Environment Access</th>
<th>Precise Floating-Point Exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>precise source</td>
<td>Varies</td>
<td>Source</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>strict</td>
<td>Varies</td>
<td>Source</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Precise Floating-Point Exceptions

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value Safety</th>
<th>Floating-Point Expression Evaluation</th>
<th>Floating-Point Contractions</th>
<th>Floating-Point Environment Access</th>
<th>Precise Floating-Point Exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>fast=1  (default)</td>
<td>Unsafe</td>
<td>Unknown</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>fast=2</td>
<td>Unsafe</td>
<td>Unknown</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>except</td>
<td>Unaffected</td>
<td>Source</td>
<td>Unaffected</td>
<td>Unaffected</td>
<td>Yes</td>
</tr>
<tr>
<td>except-</td>
<td>Unaffected</td>
<td>Source</td>
<td>Unaffected</td>
<td>Unaffected</td>
<td>No</td>
</tr>
</tbody>
</table>

**NOTE.** It is illegal to specify the `except` keyword in an unsafe safety mode.

Based on the objectives of an application, you can choose to use different sets of compiler options and keywords to enable or disable certain optimizations, so that you can get the desired result.

**See Also**
- Understanding Floating-point Operations
- Using `-fp-model (/fp)` Option

**Using the `-fp-model (/fp)` Option**

The `-fp-model (Linux* and Mac OS* X) or `/fp` (Windows*) option allows you to control the optimizations on floating-point data. You can use this option to tune the performance, level of accuracy, or result consistency for floating-point applications across platforms and optimization levels.

For applications that do not require support for denormalized numbers, the `-fp-model` or `/fp` option can be combined with the `-ftz (Linux* and Mac OS* X) or `/Qftz (Windows*) option to flush denormalized results to zero in order to obtain improved runtime performance on processors based on all Intel architectures (IA-32, Intel® 64, and IA-64 architectures).

You can use keywords to specify the semantics to be used. Possible values of the keywords are as follows:
<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>precise</td>
<td>Enables value-safe optimizations on floating-point data and rounds intermediate results to source-defined precision.</td>
</tr>
<tr>
<td>fast[=1</td>
<td>2]</td>
</tr>
<tr>
<td>strict</td>
<td>Enables precise and except, disables contractions, and enables the property that allows modification of the floating-point environment.</td>
</tr>
<tr>
<td>source</td>
<td>Enables value-safe optimizations on floating-point data and rounds intermediate results to source-defined precision (same as precise keyword).</td>
</tr>
<tr>
<td>[no-]except</td>
<td>Determines whether strict floating-point exception semantics are used.</td>
</tr>
</tbody>
</table>

The default value of the option is -fp-model fast=1 or /fp:fast=1, which means that the compiler uses more aggressive optimizations on floating-point calculations.

**NOTE.** Using the default option keyword -fp-model fast or /fp:fast, you may get significant differences in your result depending on whether the compiler uses x87 or SSE2 instructions to implement floating-point operations. Results are more consistent when the other option keywords are used.

Several examples are provided to illustrate the usage of the keywords. These examples show:

- A small example of source code
  Note that the same source code is considered in all the included examples.
- The semantics that are used to interpret floating-point calculations in the source code
- One or more possible ways the compiler may interpret the source code
  Note that there are several ways the compiler may interpret the code; we show just some of these possibilities.
Example source code:
REAL T0, T1, T2;
...
T0 = 4.0E + 0.1E + T1 + T2;

When this option is specified, the compiler applies the following semantics:

• Additions may be performed in any order
• Intermediate expressions may use single, double, or extended double precision
• The constant addition may be pre-computed, assuming the default rounding mode

Using these semantics, some possible ways the compiler may interpret the original code are given below:
REAL T0, T1, T2;
...
T0 = (T1 + T2) + 4.1E;
REAL T0, T1, T2;
...
T0 = (T1 + 4.1E) + T2;

**-fp-model source or /fp:source**

This setting is equivalent to -fp-model precise or /fp:precise on systems based on the Intel® 64 architecture.

Example source code:
REAL T0, T1, T2;
...
T0 = 4.0E + 0.1E + T1 + T2;

When this option is specified, the compiler applies the following semantics:

• Additions are performed in program order
• Intermediate expressions use the precision specified in the source code, that is, single-precision
• The constant addition may be pre-computed, assuming the default rounding mode

Using these semantics, a possible way the compiler may interpret the original code is shown below:

```plaintext
REAL T0, T1, T2;
...
T0 = ((4.1E + T1) + T2);
```

**-fp-model strict or /fp:strict**

Example source code:

```plaintext
REAL T0, T1, T2;
...
T0 = 4.0E + 0.1E + T1 + T2;
```

When this option is specified, the compiler applies the following semantics:

• Additions are performed in program order
• Intermediate expressions always use source precision in modes other than fast.
• The constant addition is not pre-computed because there is no way to tell what rounding mode will be active when the program runs.

Using these semantics, a possible way the compiler may interpret the original code is shown below:

```plaintext
REAL T0, T1, T2;
...
T0 = REAL (((REAL)4.0E + (REAL)0.1E) + (REAL)T1) + (REAL)T2);
```

Denormal Numbers

A normalized number is a number for which both the exponent (including bias) and the most significant bit of the mantissa are non-zero. For such numbers, all the bits of the mantissa contribute to the precision of the representation.

The smallest normalized single-precision floating-point number greater than zero is about $1.1754943^{-38}$. Smaller numbers are possible, but those numbers must be represented with a zero exponent and a mantissa whose leading bit(s) are zero, which leads to a loss of precision. These numbers are called denormalized numbers or denormals (newer specifications refer to these as subnormal numbers).

Denormal computations use hardware and/or operating system resources to handle denormals; these can cost hundreds of clock cycles.

- Denormal computations take much longer to calculate on processors based on IA-32 and Intel® 64 architectures than normal computations.
- Denormals are computed in software on processors based on the IA-64 architecture. The computation usually requires hundreds of clock cycles that results in excessive kernel time.

There are several ways to avoid denormals and increase the performance of your application:

- Scale the values into the normalized range.
- Use a higher precision data type with a larger range.
- Flush denormals to zero.

Floating-point Environment

The floating-point environment is a collection of registers that control the behavior of the floating-point machine instructions and indicate the current floating-point status. The floating-point environment can include rounding mode controls, exception masks, flush-to-zero (FTZ) controls, exception status flags, and other floating-point related features.
For example, on IA-32 and Intel® 64 architectures, bit 15 of the MXCSR register enables the flush-to-zero mode, which controls the masked response to an single-instruction multiple-data (SIMD) floating-point underflow condition.

The floating-point environment affects most floating-point operations; therefore, correct configuration to meet your specific needs is important. For example, the exception mask bits define which exceptional conditions will be raised as exceptions by the processor. In general, the default floating-point environment is set by the operating system. You don't need to configure the floating-point environment unless the default floating-point environment does not suit your needs.

There are several methods available if you want to modify the default floating-point environment. For example, you can use inline assembly, compiler built-in functions, library functions, or command line options.

Changing the default floating-point environment affects runtime results only. This does not affect any calculations that are pre-computed at compile time.

Setting the FTZ and DAZ Flags

In Intel® processors, the flush-to-zero (FTZ) and denormals-are-zero (DAZ) flags in the MXCSR register are used to control floating-point calculations. The Intel® Streaming SIMD (Single Instruction Multiple Data) Extensions (Intel® SSE) and the Intel® SSE 2 instructions, including scalar and vector instructions, benefit from enabling the FTZ and DAZ flags respectively. Floating-point computations using these Intel® SSE instructions are accelerated when the FTZ and DAZ flags are enabled and thus the performance of the application improves.

You can use the -ftz (Linux* and Mac OS* X) or /Qftz (Windows*) option to flush denormal results to zero when the application is in the gradual underflow mode. This option may improve performance if the denormal values are not critical to your application's behavior. The -ftz and /Qftz options, when applied to the main program, set the FTZ and the DAZ hardware flags. The -no-ftz and /Qftz- options leave the flags as they are.

The following table describes how the compiler processes denormal values based on the status of the FTZ and DAZ flags:
When set to ON, the compiler...

- **FTZ** (flush-to-zero)
  - Sets denormal results from floating-point calculations to zero

- **DAZ** (denormals-are-zero)
  - Treats denormal values used as input to floating-point instructions as zero

When set to OFF, the compiler...

- **FTZ**
  - Does not change the denormal results

- **DAZ**
  - Does not change the denormal instruction inputs

Supported on

- IA-64, Intel® 64 architectures, and some IA-32 architectures
- Intel® 64 architecture and some IA-32 architecture

- FTZ and DAZ are not supported on all IA-32 architectures. The FTZ flag is supported only on IA-32 architectures that support Intel® SSE instructions.
- On systems based on the IA-64 architecture, FTZ always works, while on systems based on the IA-32 and Intel® 64 architectures, FTZ only applies to Intel® SSE instructions. Hence, if your application happens to generate denormals using x87 instructions, FTZ does not apply.
- DAZ and FTZ flags are not compatible with IEEE Standard 754, so you should only consider enabling them when strict compliance to the IEEE standard is not required.

Options `-ftz` and `/Qftz` are performance options. Setting these options does not guarantee that all denormals in a program are flushed to zero. They only cause denormals generated at run-time to be flushed to zero.

On Intel®64 and IA-32 systems, the compiler, by default, inserts code into the main routine to set the FTZ and DAZ flags. When `-ftz` or `/Qftz` option is used on IA-32 systems with the option `-msse2` or `/arch:sse2`, the compiler will insert code to conditionally set FTZ/DAZ flags based on a run-time processor check. The `-no-ftz` (Linux* and Mac OS* X) or `/Qftz-` (Windows) will prevent the compiler from inserting any code that might set FTZ or DAZ flags.

When `-ftz` or `/Qftz` is used in combination with an Intel® SSE-enabling option on systems based on the IA-32 architecture (for example, `-msse2` or `/arch:sse2`), the compiler will insert code in the main routine to set FTZ and DAZ. When `-ftz` or `/Qftz` is used without such an option, the compiler will insert code to conditionally set FTZ/DAZ based on a run-time processor check. `-no-ftz` (Linux and Mac OS X) or `/Qftz-` (Windows) will prevent the compiler from inserting any code that might set FTZ or DAZ.

The `-ftz` or `/Qftz` option only has an effect when the main program is being compiled. It sets the FTZ/DAZ mode for the process. The initial thread and any threads subsequently created by that process will operate in the FTZ/DAZ mode.
On systems based on the IA-64 architecture, optimization option O3 sets -ftz and /Qftz; optimization option O2 sets -no-ftz (Linux) and /Qftz- (Windows). On systems based on the IA-32 and Intel® 64 architectures, every optimization option O level, except O0, sets -ftz and /Qftz.

If this option produces undesirable results of the numerical behavior of your program, you can turn the FTZ/DAZ mode off by using -no-ftz or /Qftz- in the command line while still benefiting from the O3 optimizations.

For some non-Intel processors, the flags can be set manually by calling the following Intel Fortran intrinsic:

```
RESULT = FOR_SET_FPE (FOR_M_ABRUPT_UND)
```

### Checking the Floating-point Stack State

On systems based on the IA-32 architectures, when an application calls a function that returns a floating-point value, the returned floating-point value is supposed to be on the top of the floating-point stack. If the return value is not used, the compiler must pop the value off of the floating-point stack in order to keep the floating-point stack in the correct state.

On systems based on Intel(R) 64 architectures, floating-point values are usually returned in the xmm0 register. The floating-point stack is used only when the return value is an internal 80-bit floating-point data type on Linux* and Mac OS* X systems.

If the application calls a function without defining or incorrectly defining the function's prototype, the compiler cannot determine if the function must return a floating-point value. Consequently, the return value is not popped off the floating-point stack if it is not used. This can cause the floating-point stack to overflow.

The overflow of the stack results in two undesirable situations:

- A NaN value gets involved in the floating-point calculations
- The program results become unpredictable; the point where the program starts making errors can be arbitrarily far away from the point of the actual error.
For systems based on the IA-32 and Intel® 64 architectures, the `-fp-stack-check (Linux* and Mac OS* X) or `/Qfp-stack-check (Windows*)` option checks whether a program makes a correct call to a function that should return a floating-point value. If an incorrect call is detected, the option places a code that marks the incorrect call in the program. The `-fp-stack-check (Linux* and Mac OS* X) or `/Qfp-stack-check (Windows*)` option marks the incorrect call and makes it easy to find the error.

**NOTE.** The `-fp-stack-check (Linux* and Mac OS* X) and the `/Qfp-stack-check (Windows*)` option causes significant code generation after every function/subroutine call to ensure that the floating-point stack is maintained in the correct state. Therefore, using this option slows down the program being compiled. Use the option only as a debugging aid to find floating point stack underflow/overflow problems, which can be otherwise hard to find.

Overview: Tuning Performance

This section describes several programming guidelines that can help you improve the performance of a floating-point applications:

- Avoid exact floating-point comparisons
- Avoid exceeding representable ranges during computation; handling these cases can have a performance impact.
- Use REAL variables in single precision format unless the extra precision obtained through DOUBLE or REAL*8 is required because a larger precision formation will also increase memory size and bandwidth requirements. See Using Efficient Data Types section.
- Reduce the impact of denormal exceptions for all supported architectures.
- Avoid mixed data type arithmetic expressions.

Avoiding Exact Floating-point Comparison

It is unsafe for applications to rely on exact floating-point comparisons. Slight variations in rounding can change the outcome of such comparisons, leading to non-convergence or other unexpected behavior.

Tests for equality of floating-point quantities should be made within some tolerance related to the expected precision of the calculation, for example, by using the Fortran intrinsic function EPSILON. The following examples demonstrate the concept:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>if (foo() == 2.0)</td>
</tr>
</tbody>
</table>

Where foo() may be as close to 2.0 as can be imagined without actually exactly matching 2.0. You can improve the behavior of such codes by using inexact floating-point comparisons or fuzzy comparisons to test a value to within a certain tolerance, as shown below:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>epsilon = 1E-8;</td>
</tr>
<tr>
<td>if (abs(foo()) - 2.0) &lt;= epsilon)</td>
</tr>
</tbody>
</table>
Handling Floating-point Array Operations in a Loop Body

Following the guidelines below will help autovectorization of the loop.

- Statements within the loop body may contain float or double operations (typically on arrays). The following arithmetic operations are supported: addition, subtraction, multiplication, division, negation, square root, MAX, MIN, and mathematical functions such as SIN and COS.
- Writing to a single-precision scalar/array and a double scalar/array within the same loop decreases the chance of autovectorization due to the differences in the vector length (that is, the number of elements in the vector register) between float and double types. If autovectorization fails, try to avoid using mixed data types.

Reducing the Impact of Denormal Exceptions

Denormalized floating-point values are those that are too small to be represented in the normal manner; that is, the mantissa cannot be left-justified. Denormal values require hardware or operating system interventions to handle the computation, so floating-point computations that result in denormal values may have an adverse impact on performance.

There are several ways to handle denormals to increase the performance of your application:

- Scale the values into the normalized range
- Use a higher precision data type with a larger range
- Flush denormals to zero

For example, you can translate them to normalized numbers by multiplying them using a large scalar number, doing the remaining computations in the normal space, then scaling back down to the denormal range. Consider using this method when the small denormal values benefit the program design.

If you change the declaration of a variable you might also need to change the libraries you call to use the variable Another strategy that might result in increased performance is to increase the amount of precision of intermediate values using the -fp-model [double|extended] option. However, this strategy might not eliminate all denormal exceptions, so you must experiment with the performance of your application.
If you change the type declaration of a variable, you might also need to change associated library calls, unless these are generic. Another strategy that might result in increased performance is to increase the amount of precision of intermediate values using the `-fp-model [double|extended]` option. However, this strategy might not eliminate all denormal exceptions, so you must experiment with the performance of your application. You should verify that the gain in performance from eliminating denormals is greater than the overhead of using a data type with higher precision and greater dynamic range.

Finally, in many cases denormal numbers can be treated safely as zero without adverse effects on program results. Depending on the target architecture, use flush-to-zero (FTZ) options.

**IA-32 and Intel® 64 Architectures**

These architectures take advantage of the FTZ (flush-to-zero) and DAZ (denormals-are-zero) capabilities of Intel® Streaming SIMD Extensions (Intel® SSE) instructions.

On Intel®64 and IA-32-based systems, the compiler, by default, inserts code into the main routine to enable FTZ and DAZ at optimization levels higher than `-O0`. To enable FTZ and DAZ at `-O0`, compile the source file containing PROGRAM using `-ftz` or `/Qftz` option. When `-ftz` or `/Qftz` option is used on IA-32-based systems with the option `-mia32` or `/arch:IA32`, the compiler inserts code to conditionally enable FTZ and DAZ flags based on a run-time processor check.

**NOTE.** After using flush-to-zero, ensure that your program still gives correct results when treating denormalized values as zero.

**IA-64 Architecture**

Enable the FTZ mode by using the `-ftz` (Linux and Mac OS X) or `/Qftz` (Windows) option on the source file containing PROGRAM. The `-O3` (Linux and Mac OS X) or `/O3` (Windows) option automatically enables `-ftz` or `/Qftz`.

**NOTE.** After using flush-to-zero, ensure that your program still gives correct results when treating denormalized values as zero.

Avoiding Mixed Data Type Arithmetic Expressions

Avoid mixing integer and floating-point (REAL) data in the same computation. Expressing all numbers in a floating-point arithmetic expression (assignment statement) as floating-point values eliminates the need to convert data between fixed and floating-point formats. Expressing all numbers in an integer arithmetic expression as integer values also achieves this. This improves run-time performance.

For example, assuming that I and J are both INTEGER variables, expressing a constant number (2.) as an integer value (2) eliminates the need to convert the data. The following examples demonstrate inefficient and efficient code.

Examples

<table>
<thead>
<tr>
<th>Example 1: Inefficient Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER I, J</td>
</tr>
<tr>
<td>I = J / 2.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Example 2: Efficient Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER I, J</td>
</tr>
<tr>
<td>I = J / 2</td>
</tr>
</tbody>
</table>

Special Considerations for Auto-Vectorization of the Innermost Loops

Auto-vectorization of an innermost loop packs multiple data elements from consecutive loop iterations into a vector register, each of which is 128-bit in size.

Consider a loop that uses different sized data, for example, REAL and DOUBLE PRECISION. For REAL data, the compiler tries to pack data elements from four (4) consecutive iterations (32 bits x 4 = 128 bits). For DOUBLE PRECISION data, the compiler tries to pack data elements from two (2) consecutive iterations (64 bits x 2 = 128 bits). Because of the mismatched number of iterations, the compiler sometimes fails to perform auto-vectorization of the loop, after trying to automatically remedy the situation.

If your attempt to auto-vectorize an innermost loop fails, it is a good practice to try using the same sized data. INTEGER and REAL are considered same sized data since both are 32-bit in size.
### Examples

**Example 1: Non-auto-vectorizable code**

```fortran
DOUBLE PRECISION A(N), B(N)
REAL C(N), D(N)
DO I=1, N
  A(I)=D(I)
  C(I)=B(I)
ENDDO
```

**Example 2: Auto-vectorizable after automatic distribution into two loops**

```fortran
DOUBLE PRECISION A(N), B(N)
REAL C(N), D(N)
DO I=1, N
  A(I)=B(I)
  C(I)=D(I)
ENDDO
```

**Example 3: Auto-vectorizable as one loop**

```fortran
REAL A(N), B(N)
REAL C(N), D(N)
DO I=1, N
  A(I)=B(I)
  C(I)=D(I)
ENDDO
```
Using Efficient Data Types

In cases where more than one data type can be used for a variable, consider selecting the data types based on the following hierarchy, listed from most to least efficient:

- Integer
- Single-precision real, expressed explicitly as REAL, REAL (KIND=4), or REAL*4
- Double-precision real, expressed explicitly as DOUBLE PRECISION, REAL (KIND=8), or REAL*8
- Extended-precision real, expressed explicitly as REAL (KIND=16) or REAL*16

However, keep in mind that in an arithmetic expression, you should avoid mixing integer and floating-point data.
Handling Floating-point Exceptions

Overview: Controlling Floating-point Exceptions

When developing applications, you may need to control the exceptions that can occur during the run-time processing of floating-point numbers. These exceptions can be categorized into specific types: overflow, divide-by-zero, underflow, and invalid operations.

Overflow

Overflow is signaled whenever the destination format's largest finite number is exceeded in magnitude by what would have been the rounded floating-point result. The result computed is rounding mode specific:

- Round-to-nearest (default): +/- Infinity in specified precision
- Round-to-zero: +/- Maximum Number in specified precision
- Round-to+Infinity: +Infinity or -(Maximum Positive Number) in specified precision
- Round-to--Infinity: (Maximum Positive Number) or -Infinity in specified precision

For example, in round-to-nearest mode 1.E30 * 1.E30 overflows the single-precision floating-point range and results in a +Infinity; -1.E30 * 1.E30 results in a -Infinity.

Divide-by-zero

Divide-by-zero is signaled when the divisor is zero and the dividend is a finite nonzero number. The computed result is a correctly signed Infinity.

For example, 2.0E0/+0.0 produces a divide-by-zero exception and results in a +Infinity; -2.0E0/+0.0 produces a divide-by-zero exception and results in a -Infinity.

Underflow

Underflow occurs when a computed result (of an add, subtract, multiply, divide, or math function call) falls beyond the minimum range in magnitude of normalized numbers of the floating-point data type. Each floating-point type (32-, 64-, and 128-bit) has a denormalized range where very small numbers can be represented with some loss of precision. This is called gradual underflow. For example, the lower bound for normalized single-precision floating-point is approximately 1.E-38,
while the lower bound for denormalized single-precision floating-point is approximately 1.E-45. Results falling below the lower bound of the denormalized range simply become zero. 1.E-30 / 1.E10 underflows the normalized range but not the denormalized range so the result is the denormal value 1.E-40. 1.E-30 / 1.E30 underflows the entire range and the result is zero.

**Invalid operation**

Invalid occurs when operands to the basic floating-point operations or math function inputs produce an undefined (QNaN) result. Some examples include:

- SNaN operand in any floating-point operation or math function call
- Division of zeroes: (+/-0.0)/(+/-0.0)
- Sum of Infinities having different signs: Infinity + (-Infinity)
- Difference of Infinities having the same sign: (+/-Infinity) - (+/-Infinity)
- Product of signed Infinities with zero: (+/-Inf) * 0
- Math Function Domain Errors: log(negative), sqrt(negative), asin(|x|>1)

With the Intel® Compiler, you can use the `-fpe` (Linux* and Mac OS* X) or `/fpe` (Windows*) option to control floating-point exceptions.

**Handling Floating-point Exceptions**

If a floating-point exception is disabled (its bit is set to 1 with SETCONTROLFPQQ (x87 arithmetic only), it will not generate an interrupt signal if it occurs. The floating-point process may return an appropriate special value (for example, NaN or signed infinity) or may return an acceptable value (for example, in the case of a denormal operand), and the program will continue. If a floating-point exception is enabled (its bit is set to 0), it will generate an interrupt signal (software interrupt) if it occurs.

The following table lists the floating-point exception signals:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Value in Hex</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPE$INVALID</td>
<td>#81</td>
<td>Invalid result</td>
</tr>
<tr>
<td>FPE$DENORMAL</td>
<td>#82</td>
<td>Denormal operand</td>
</tr>
<tr>
<td>FPE$ZERODIVIDE</td>
<td>#83</td>
<td>Divide by zero</td>
</tr>
<tr>
<td>FPE$OVERFLOW</td>
<td>#84</td>
<td>Overflow</td>
</tr>
</tbody>
</table>
If a floating-point exception interrupt occurs and you do not have an exception handling routine, the run-time system will respond to the interrupt according to the behavior selected by the compiler option /fpe. Remember, interrupts only occur if an exception is enabled (set to 0).

If you do not want the default system exception handling, you need to write your own interrupt handling routine:

- Write a function that performs whatever special behavior you require on the interrupt.
- Register that function as the procedure to be called on that interrupt with SIGNALQQ.

Note that your interrupt handling routine must use the cDEC$ ATTRIBUTES option C.

The drawback of writing your own routine is that your exception-handling routine cannot return to the process that caused the exception. This is because when your exception-handling routine is called, the floating-point processor is in an error condition, and if your routine returns, the processor is in the same state, which will cause a system termination. Your exception-handling routine can therefore either branch to another separate program unit or exit (after saving your program state and printing an appropriate message). You cannot return to a different statement in the program unit that caused the exception-handling routine, because a global GOTO does not exist, and you cannot reset the status word in the floating-point processor.

If you need to know when exceptions occur and also must continue if they do, you must disable exceptions so they do not cause an interrupt, then poll the floating-point status word at intervals with GETSTATUSFPQQ (IA-32 architecture only) to see if any exceptions occurred. To clear the status word flags, call the CLEARSTATUSFPQQ (IA-32 architecture only) routine.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Value in Hex</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPE$UNDERFLOW</td>
<td>#85</td>
<td>Underflow</td>
</tr>
<tr>
<td>FPE$INEXACT</td>
<td>#86</td>
<td>Inexact precision</td>
</tr>
</tbody>
</table>
Polling the floating-point status word at intervals creates processing overhead for your program. In general, you will want to allow the program to terminate if there is an exception. An example of an exception-handling routine follows. The comments at the beginning of the SIGTEST.F90 file describe how to compile this example.

! SIGTEST.F90

! Establish the name of the exception handler as the function to be invoked if an exception happens.
! The exception handler hand_fpe is attached below.

USE IFPORT

INTERFACE

FUNCTION hand_fpe (sigid, except)

!DEC$ ATTRIBUTES C :: hand_fpe

INTEGER(4) hand_fpe

INTEGER(2) sigid, except

END FUNCTION

END INTERFACE

INTEGER(4) iret
REAL(4) r1, r2
r1 = 0.0
iret = SIGNALQQ(SIG$FPE, hand_fpe)
WRITE(*,*) 'Set exception handler. Return = ', iret

! Cause divide-by-zero exception
r1 = 0.0
r2 = 3/r1

END

! Exception handler routine hand_fpe

FUNCTION hand_fpe (signum, excnum)

!DEC$ ATTRIBUTES C :: hand_fpe

USE IFPORT

INTEGER(2) signum, excnum
WRITE(*,*) 'In signal handler for SIG$FPE'
WRITE(*,*) 'signum = ', signum
WRITE(*,*) 'exception = ', excnum
SELECT CASE(excnum)
  CASE( FPE$INVALID )
    STOP ' Floating point exception: Invalid number'
  CASE( FPE$DENORMAL )
    STOP ' Floating point exception: Denormalized number'
  CASE( FPE$ZERODIVIDE )
    STOP ' Floating point exception: Zero divide'
  CASE( FPE$OVERFLOW )
    STOP ' Floating point exception: Overflow'
  CASE( FPE$UNDERFLOW )
    STOP ' Floating point exception: Underflow'
  CASE( FPE$INEXACT )
    STOP ' Floating point exception: Inexact precision'
  CASE DEFAULT
    STOP ' Floating point exception: Non-IEEE type'
END SELECT
hand_fpe = 1
END

**File fordef.for and Its Usage**

The parameter file fordef.for contains symbols and INTEGER*4 values corresponding to the classes of floating-point representations. Some of these classes are exceptional ones such as bit patterns that represent positive denormalized numbers.

With this file of symbols and with the FP_CLASS intrinsic function, you have the flexibility of identifying exceptional numbers so that, for example, you can replace positive and negative denormalized numbers with true zero.
The following is a simple example of identifying floating-point bit representations:

```fortran
include 'fordef.for'

real*4 a
integer*4 class_of_bits
a = 57.0
class_of_bits = fp_class(a)
if ( class_of_bits .eq. for_k_fp_pos_norm .or. &
     class_of_bits .eq. for_k_fp_neg_norm ) then
  print *, a, ' is a non-zero and non-exceptional value'
else
  print *, a, ' is zero or an exceptional value'
end if
end
```

In this example, the symbol `for_k_fp_pos_norm` in the file `fordef.for` plus the REAL*4 value 57.0 to the `fp_class` intrinsic function results in the execution of the first print statement.

The table below explains the symbols in the file `fordef.for` and their corresponding floating-point representations.

<table>
<thead>
<tr>
<th>Symbol Name</th>
<th>Class of Floating-Point Bit Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR_K_FP_SNAN</td>
<td>Signaling NaN</td>
</tr>
<tr>
<td>FOR_K_FP_QNAN</td>
<td>Quiet NaN</td>
</tr>
<tr>
<td>FOR_K_FP_POS_INF</td>
<td>Positive infinity</td>
</tr>
<tr>
<td>FOR_K_FP_NEG_INF</td>
<td>Negative infinity</td>
</tr>
<tr>
<td>FOR_K_FP_POS_NORM</td>
<td>Positive normalized finite number</td>
</tr>
<tr>
<td>FOR_K_FP_NEG_NORM</td>
<td>Negative normalized finite number</td>
</tr>
<tr>
<td>FOR_K_FP_POS_DENORM</td>
<td>Positive denormalized number</td>
</tr>
<tr>
<td>FOR_K_FP_NEG_DENORM</td>
<td>Negative denormalized number</td>
</tr>
</tbody>
</table>
### Symbol Name | Class of Floating-Point Bit Representation
---|---
FOR\_K\_FP\_POS\_ZERO | Positive zero
FOR\_K\_FP\_NEG\_ZERO | Negative zero

Another example of using file `fordef.for` and intrinsic function `FP\_CLASS` follows. The goals of this program are to quickly read any 32-bit pattern into a REAL\*4 number from an unformatted file with no exception reporting and to replace denormalized numbers with true zero:

```fortran
#include 'fordef.for'
real*4 a(100)
integer*4 class_of_bits
! open an unformatted file as unit 1
! ...
read (1) a
do i = 1, 100
   class_of_bits = fp_class(a(i))
   if ( class_of_bits .eq. for\_k\_fp\_pos\_denorm .or. &
       class_of_bits .eq. for\_k\_fp\_neg\_denorm ) then
      a(i) = 0.0
   end if
end do
close (1)
end
```

You can compile this program with any value of `-fpe` (Linux* and Mac OS* X) or `/fpe:` (Windows*). Intrinsic function `FP\_CLASS` helps to find and replace denormalized numbers with zeroes before the program can attempt to perform calculations on the denormalized numbers.

On the other hand, if this program did not replace denormalized numbers read from unit 1 with zeroes and the program was compiled with `-fpe0` or `/fpe:0`, then the first attempted calculation on a denormalized number would result in a floating-point exception. If you compile with `/fpe:0` flush-to-zero is enabled. If the resulting calculation creates a divide-by-zero, overflow, or invalid operation, then the application should abort with a floating-point exception. Otherwise, a program using the data will run to completion, perhaps faster and with different answers.
File `fordef.for` and intrinsic function `FP_CLASS` can work together to identify NaNs. A variation of the previous example would contain the symbols `for_k_fp_snan` and `for_k_fp_qnan` in the IF statement. A faster way to do this is based on the intrinsic `ISNAN` function. One modification of the previous example, using `ISNAN`, follows:

```fortran
! The ISNAN function does not need file fordef.for
real*4 a(100)
! open an unformatted file as unit 1
! ...
read (1) a
do i = 1, 100
   if ( isnan (a(i)) ) then
      print *, 'Element ', i, ' contains a NaN'
   end if
end do
close (1)
end
```

You can compile this program with any value of `-fpe:n` or `/fpe:n`.

### Setting and Retrieving Floating-point Status and Control Words (IA-32)

#### Overview: Setting and Retrieving Floating-point Status and Control Word

The FPU (floating-point unit) on systems based on the IA-32 architecture contains eight floating-point registers the system uses for numeric calculations, status and control words, and error pointers. You normally need to consider only the status and control words, and then only when customizing your floating-point environment.

The FPU status and control words correspond to 16-bit registers whose bits hold the value of a state of the FPU or control its operation. Intel Fortran defines a set of symbolic constants to set and reset the proper bits in the status and control words.

**NOTE.** The symbolic constants and the library routines used to read and write the control and status registers only affect the x87 control and status registers. They do not affect the MXCSR register (the control and status register for the Intel(R) SSE and Intel(R) SSE2 instructions).
They do not affect the MXCSR (the control and status register for the Intel(R) SSE and Intel(R) SSE2 instructions). For example:

USE IFPORT

INTEGER(2) status, control, controlo, mask_all_traps

CALL GETCONTROLFPQQ(control)

WRITE (*, 9000) 'Control word: ', control
!  Save old control word
controlo = control
!  Clear the rounding control flags
control = IAND(control, NOT(FPCW$MCW_RC))
!  Set new control to round up
control = IOR(control, FPCW$UP)
CALL SETCONTROLFPQQ(control)

CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control

! Demonstrate setting and clearing exception mask flags

mask_all_traps = FPCW$INVALID + FPCW$DENORMAL + 
   FPCW$ZERODIVIDE + FPCW$OVERFLOW + 
   FPCW$UNDERFLOW + FPCW$INEXACT

!  Clear the exception mask flags
control = IAND(control, NOT(FPCW$MCW_EM))
!  Set new exception mask to disallow overflow
!  (i.e., enable overflow traps)
!  but allow (i.e., mask) all other exception conditions.
control = IOR(control, IEOR(mask_all_traps, FPCW$OVERFLOW))
CALL SETCONTROLFPQQ(control)

CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control

9000 FORMAT (1X, A, Z4)
The status and control symbolic constants (such as FPCW$OVERFLOW and FPCW$CHOP in the preceding example) are defined as INTEGER(2) parameters in the module IFORT.F90 in the ...\INCLUDE folder. The status and control words are logical combinations (such as with .AND.) of different parameters for different FPU options.

The name of a symbolic constant takes the general form name$option. The prefix name is one of the following:

<table>
<thead>
<tr>
<th>name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPSW</td>
<td>Floating-point status word</td>
</tr>
<tr>
<td>FPCW</td>
<td>Floating-point control word</td>
</tr>
<tr>
<td>SIG</td>
<td>Signal</td>
</tr>
<tr>
<td>FPE</td>
<td>Floating-point exception</td>
</tr>
<tr>
<td>MTH</td>
<td>Math function</td>
</tr>
</tbody>
</table>

The suffix option is one of the options available for that name. The parameter name$option corresponds either to a status or control option (for example, FPSW$ZERODIVIDE, a status word parameter that shows whether a zero-divide exception has occurred or not) or name$option corresponds to a mask, which sets all symbolic constants to 1 for all the options of name. You can use the masks in logical functions (such as IAND, IOR, and NOT) to set or to clear all options for the specified name. The following sections define the options and illustrate their use with examples.

You can control the floating-point processor options (on systems based on the IA-32 architecture) and find out its status with the run-time library routines GETSTATUSFPQQ (IA-32 architecture only), GETCONTROLFPQQ (IA-32 architecture only), and SETCONTROLFPQQ (IA-32 architecture only). Examples of using these routines also appear in the following sections.

Understanding Floating-point Status Word

On systems based on the IA-32 architecture, the FPU status word includes bits that show the floating-point exception state of the processor. The status word parameters describe six exceptions: invalid result, denormalized operand, zero divide, overflow, underflow and inexact precision. These are described in the section, Loss of Precision Errors. When one of the bits is set to 1, it means a past floating-point operation produced that exception type. (Intel Fortran initially clears all status bits. It does not reset the status bits before performing additional floating-point operations after an exception occurs. The status bits accumulate.)

The following table shows the floating-point exception status parameters:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Value in Hex</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPSW$MSW_EM</td>
<td>#003F</td>
<td>Status Mask (set all bits to 1)</td>
</tr>
<tr>
<td>FPSW$INVALID</td>
<td>#0001</td>
<td>An invalid result occurred</td>
</tr>
<tr>
<td>FPSW$DENORMAL</td>
<td>#0002</td>
<td>A denormal operand occurred</td>
</tr>
<tr>
<td>FPSW$ZERODIVIDE</td>
<td>#0004</td>
<td>A divide by zero occurred</td>
</tr>
<tr>
<td>FPSW$OVERFLOW</td>
<td>#0008</td>
<td>An overflow occurred</td>
</tr>
<tr>
<td>FPSW$UNDERFLOW</td>
<td>#0010</td>
<td>&gt;An underflow occurred</td>
</tr>
<tr>
<td>FPSW$INEXACT</td>
<td>#0020</td>
<td>Inexact precision occurred</td>
</tr>
</tbody>
</table>

You can find out which exceptions have occurred by retrieving the status word and comparing it to the exception parameters. For example:

```fortran
USE IFPORT
INTEGER(2) status
CALL GETSTATUSFPQQ(status)
IF (IAND (status, FPSW$INEXACT) > 0) THEN
   WRITE (*, *) "Inexact precision has occurred"
ELSE IF (IAND (status, FPSW$DENORMAL) > 0) THEN
   WRITE (*, *) "Denormal occurred"
END IF
```

To clear the status word flags, call the CLEARSTATUSFPQQ (IA-32 architecture only) routine.
NOTE. The GETSTATUSFPQQ and CLEARSTATUSFPQQ routines only affect the x87 status register. They do not affect the MXCSR register (the control and status register for the Intel® SSE and Intel® SSE2 instructions).

Floating-point Control Word Overview

On systems based on the IA-32 architecture, the FPU control word includes bits that control the FPU’s precision, rounding mode, and whether exceptions generate signals if they occur. You can read the control word value with GETCONTROLFPQQ (IA-32 architecture only) to find out the current control settings, and you can change the control word with SETCONTROLFPQQ (IA-32 architecture only).

NOTE. The GETCONTROLFPQQ and SETCONTROLFPQQ routines only affect the x87 status register. They do not affect the MXCSR register (the control and status register for the SSE and SSE2 instructions).

Each bit in the floating-point control word corresponds to a mode of the floating-point math processor. The IFORT.F90 module file in the ...\INCLUDE folder contains the INTEGER(2) parameters defined for the control word, as shown in the following table:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Value in Hex</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCW$MCW_PC</td>
<td>#0300</td>
<td>Precision control mask</td>
</tr>
<tr>
<td>FPCW$64</td>
<td>#0300</td>
<td>64-bit precision</td>
</tr>
<tr>
<td>FPCW$53</td>
<td>#0200</td>
<td>53-bit precision</td>
</tr>
<tr>
<td>FPCW$24</td>
<td>#0000</td>
<td>24-bit precision</td>
</tr>
<tr>
<td>FPCW$MCW_RC</td>
<td>#0C00</td>
<td>Rounding control mask</td>
</tr>
<tr>
<td>FPCW$CHOP</td>
<td>#0C00</td>
<td>Truncate</td>
</tr>
<tr>
<td>FPCW$UP</td>
<td>#0800</td>
<td>Round up</td>
</tr>
<tr>
<td>FPCW$DOWN</td>
<td>#0400</td>
<td>Round down</td>

<tr>
<td>---------------------</td>
<td>--------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>FPCW$MCW_EM</td>
<td>#003F</td>
<td>Exception mask</td>
</tr>
<tr>
<td>FPCW$INVALID</td>
<td>#0001</td>
<td>Allow invalid numbers</td>
</tr>
<tr>
<td>&gt;FPCW$DENORMAL</td>
<td>#0002</td>
<td>Allow denormals (very small numbers)</td>
</tr>
<tr>
<td>FPCW$ZEROODIVIDE</td>
<td>#0004</td>
<td>Allow divide by zero</td>
</tr>
<tr>
<td>FPCW$OVERFLOW</td>
<td>#0008</td>
<td>Allow overflow</td>
</tr>
<tr>
<td>FPCW$UNDERFLOW</td>
<td>#0010</td>
<td>Allow underflow</td>
</tr>
<tr>
<td>FPCW$INEXACT</td>
<td>#0020</td>
<td>Allow inexact precision</td>
</tr>
</tbody>
</table>

The control word defaults are:
- 53-bit precision
- Round to nearest (rounding mode)
- The denormal, underflow, overflow, divide-by-zero, invalid, and inexact precision exceptions are disabled (do not generate an exception). To change exception handling, you can use the `-fpe` (Linux* and Mac OS* X) or the `/fpe` (Windows*) compiler option or the `FOR_SET_FPE` routine.

### Using Exception, Precision, and Rounding Parameters

This topic describes the exception, precision, and rounding parameters that you can use for the control word.

#### Exception Parameters

An exception is disabled if its bit is set to 1 and enabled if its bit is cleared to 0. If an exception is disabled (exceptions can be disabled by setting the flags to 1 with SETCONTROLFPQQ [IA-32 architecture only]), it will not generate an interrupt signal if it occurs. The floating-point process will return an appropriate special value (for example, NaN or signed infinity), but the program continues. You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ (IA-32 architecture only).
If errors on floating-point exceptions are enabled (by clearing the flags to 0 with SETCONTROLFPQ[IA-32 architecture only]), the operating system generates an interrupt when the exception occurs. By default these interrupts cause run-time errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

You should remember not to clear all existing settings when changing one. The values you want to change should be combined with the existing control word in an inclusive-OR operation (\texttt{IOR}) if you do not want to reset all options. For example:

\begin{verbatim}
USE IFPORT
INTEGER(2) control, newcontrol
CALL GETCONTROLFPQQ(control)
newcontrol = IOR(control, FPCW$INVALID)
! Invalid exception set (disabled).
CALL SETCONTROLFPQQ(newcontrol)
\end{verbatim}

\textbf{NOTE.} The \texttt{GETCONTROLFPQQ}, \texttt{SETCONTROLFPQQ}, and \texttt{GETSTATUSFPQQ} routines only affect the x87 status register. They do not affect the MXCSR register (the control and status register for the Intel(R) SSE and Intel(R) SSE2 instructions).

**Precision Parameters**

On systems based on the IA-32 architecture, the precision bits control the precision to which the FPU rounds floating-point numbers. For example:

\begin{verbatim}
USE IFPORT
INTEGER(2) control, holdcontrol, newcontrol
CALL GETCONTROLFPQQ(control)
! Clear any existing precision flags.
holdcontrol = IAND(control, NOT(FPCW$MCW_PC))
newcontrol = IOR(holdcontrol, FPCW$64)
! Set precision to 64 bits.
CALL SETCONTROLFPQQ(newcontrol)
\end{verbatim}
The precision options are mutually exclusive. If you set more than one, you may get an invalid mode or a mode other than the one you want. Therefore, you should clear the precision bits before setting a new precision mode.

**NOTE.** The `GETCONTROLFPQQ` and `SETCONTROLFPQQ` routines only affect the x87 status register. They do not affect the `MXCSR` register (the control and status register for the Intel(R) SSE and Intel(R) SSE2 instructions).

### Rounding Parameters

On systems based on the IA-32 architecture, the rounding flags control the method of rounding that the FPU uses. For example:

```fortran
USE IFPORT
INTEGER(2) status, control, controlo, mask_all_traps
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
> ! Save old control word
controlo = control
! Clear the rounding control flags
control = IAND(control,NOT(FPCW$MCW_RC))
! Set new control to round up
control = IOR(control,FPCW$UP)
CALL SETCONTROLFPQQ(control)
CALL GETCONTROLFPQQ(control)
WRITE (*, 9000) 'Control word: ', control
```

The rounding options are mutually exclusive. If you set more than one, you may get an invalid mode or a mode other than the one you want. Therefore, you should clear the rounding bits before setting a new rounding mode.
NOTE. The GETCONTROLFPQ and SETCONTROLFPQ routines only affect the x87 status register. They do not affect the MXCSR register (the control and status register for the Intel(R) SSE and Intel(R) SSE2 instructions).

Handling Floating-point Exceptions with the -fpe or /fpe Compiler Option

Using the -fpe or /fpe Compiler Options

The -fpe (Linux* and Mac OS* X) or /fpe:n (Windows*) option allows some control over the results of floating-point exceptions.

-fpe0 or /fpe:0 restricts floating-point exceptions by enabling the overflow, the divide-by-zero, and the invalid floating-point exceptions. The program will print an error message and abort if any of these exceptions occurs. If a floating underflow occurs, the result is set to zero and execution continues. This is called flush-to-zero. This option sets -fp-speculation=strict (Linux and Mac OS X) or /Qfp-speculation:strict (Windows) if no specific -fp-speculation or /Qfp-speculation option is specified. The -fpe0 or /fpe:0 option sets -ftz (Linux and Mac OS X) or /Qftz (Windows). To get more detailed location information about where the exception occurred, use -traceback (Linux and Mac OS X) or /traceback (Windows).

NOTE. On systems based on the IA-32 and Intel® 64 architectures, explicitly setting -fpe0 or /fpe:0 can degrade performance since the generated code stream must be synchronized after each floating-point instruction to allow for abrupt underflow fix-up.

-fpe1 or /fpe:1 restricts only floating-point underflow. Floating-point overflow, floating-point divide-by-zero, and floating-point invalid produce exceptional values (NaN and signed Infinities) and execution continues. If a floating-point underflow occurs, the result is set to zero and execution continues. The /fpe:1 option sets -ftz or /Qftz.

NOTE. On systems based on the IA-32 and Intel® 64 architectures, explicitly setting -fpe1 or /fpe:1 can degrade performance since the generated code stream must be synchronized after each floating-point instruction to allow for abrupt underflow fix-up.

-fpe3 or /fpe:3 is the default on all processors, which allows full floating-point exception behavior. Floating-point overflow, floating-point divide-by-zero, and floating-point invalid produce exceptional values (NaN and signed Infinities) and execution continues. Floating underflow is gradual: denormalized values are produced until the result becomes 0.
The -fpe or /fpe option enables exceptions in the Fortran main program only. The floating-point exception behavior set by the Fortran main program remains in effect throughout the execution of the entire program unless changed by the programmer. If the main program is not Fortran, the user can use the Fortran intrinsic FOR_SET_FPE to set the floating-point exception behavior.

When compiling different routines in a program separately, you should use the same value of n in -fpe n or /fpe:n.

An example follows:

```fortran
IMPLICIT NONE
real*4 res_uflow, res_oflow
real*4 res_dbyz, res_inv
real*4 small, big, zero, scale
small = 1.0e-30
big = 1.0e30
zero = 0.0
scale = 1.0e-10
! IEEE underflow condition (Underflow Raised)
res_uflow = small * scale
write(6,100)"Underflow: ",small, " *", scale, " = ", res_uflow
! IEEE overflow condition (Overflow Raised)
res_oflow = big * big
write(6,100)"Overflow: ", big, " *", big, " = ", res_oflow
! IEEE divide-by-zero condition (Divide by Zero Raised)
res_dbyz = -big / zero
write(6,100)"Div-by-zero: ", -big, " /", zero, " = ", res_dbyz
! IEEE invalid condition (Invalid Raised)
res_inv = zero / zero
write(6,100)"Invalid: ", zero, " /", zero, " = ", res_inv
100 format(A14,E8.1,A2,E8.1,A2,E10.1)
end
```

Consider the following command line:
ifort fpe.f90 -fpe0 -fp-model strict -g (Linux and Mac OS X)
ifort fpe.f90 /fpe:0 /fp:strict /traceback (Windows)

Output similar to the following should result:

Windows:

Underflow: 0.1E-29 * 0.1E-09 = 0.0E+00
forrtl: error (72): floating overflow

Image  PC    Routine  Line  Source
fpe.exe  0040115B Unknown Unknown Unknown
fpe.exe  0044DFC0 Unknown Unknown Unknown
fpe.exe  00433277 Unknown Unknown Unknown
kernel32.dll  7C816D4F Unknown Unknown Unknown

Linux and Mac OS X:

./a.out

Underflow: 0.1E-29 * 0.1E-09 = 0.0E+00
forrtl: error (72): floating overflow

Image  PC    Routine  Line  Source
a.out  0804A063 Unknown Unknown Unknown
a.out  08049E78 Unknown Unknown Unknown
Unknown  B746B748 Unknown Unknown Unknown
a.out  08049D31 Unknown Unknown Unknown

Aborted

The following command line uses /fpe1:

ifort fpe.f90 -fpe1 -g (Linux and Mac OS X)
ifort fpe.f90 /fpe:1 /traceback (Windows)

The following output is produced:

Underflow: 0.1E-29 * 0.1E-09 = 0.0E+00
Overflow: 0.1E+31 * 0.1E+31 = Infinity
Div-by-zero: -0.1E+31 / 0.0E+00 = -Infinity
Invalid: 0.0E+00 / 0.0E+00 = NaN
The following command line uses /fpe3:
ifort fpe.f90 -fpe3 -g (Linux and Mac OS X)
ifort fpe.f90 /fpe:3 /traceback (Windows)

The following output is produced:
Underflow: 0.1E-29 * 0.1E-09 = 0.1E-39
Overflow: 0.1E+31 * 0.1E+31 = Infinity
Div-by-zero: -0.1E+31 / 0.0E+00 = -Infinity
Invalid: 0.0E+00 / 0.0E+00 = NaN

Understanding the Impact of Application Types

The full consequences of the /fpe option depend on the type of application you are building. You only get the full support for the chosen option setting in a Fortran Console or QuickWin/Standard Graphics application, assuming you do not override the default run-time exception handler. The work to achieve the full behavior is done partly by each of the default run-time handler, the Fortran compiler, the math library, the underlying hardware, and the operating system.

Floating-point Exceptions in Fortran Console, Fortran QuickWin, and Fortran Standard Graphics Applications

When you build a console application, the compiler generates a few calls at the beginning of your Fortran main program to Fortran run-time routines that initialize the environment, either with default options or in accordance with your selected compile-time options.

For floating-point exception handling, /fpe:3 is the default. The run-time system initializes the hardware to mask all exceptions. With /fpe:3:

- The Intel Fortran run-time system does this initialization automatically (no call from the compiled code).
- The IA-32 architecture hardware automatically generates the default IEEE result for exceptional conditions.
- Because traps are masked with /fpe:3, there are no traps and you may see exceptional values like Nan’s, Infinities, and denormalized numbers in your computations.

Users can poll the floating-point status word with GETSTATUSFPQQ to see if an exception has occurred and can clear the status register with CLEARSTATUSFPQQ.
If you specify \(/\text{fpe}:0\)/, the compiler generates a call to an Intel Fortran run-time routine \(\text{FOR\_SET\_FPE}\), with an argument that unmasks all floating-point traps in the floating-point control word. In this case, the hardware does not supply the default IEEE result. It traps to the operating system, which then looks for a condition handler.

In a Fortran console or Fortran QuickWin application, the Intel Fortran run-time system provides a default condition handler unless you establish your own. For all exceptions except underflow, the run-time system just prints out an error message and aborts the application. For underflow, the run-time system replaces the result with zero. This treatment of underflow with \(/\text{fpe}:0\) is called abrupt underflow to 0 (zero), as opposed to gradual underflow to 0 provided with \(/\text{fpe}:3\).

Fixing up underflow results to zero can significantly degrade the performance of your application based on IA-32 architecture. If you are experiencing a large number of underflows, consider changing your code to avoid underflows or consider masking underflow traps and allowing the hardware to operate on denormalized numbers. The IA-32 architecture based hardware is designed to operate correctly in the denormalized range and doing so is much faster than trapping to fix up a result to zero.

Another important point to understand about selecting the \(/\text{fpe}\) option is that the generated code must support the trapping mode. When an IA-32 architecture based floating-point instruction generates an exceptional result, you do not necessarily get a trap. The instruction must be followed by an \(\text{fwait}\) instruction or another floating-point operate instruction to cause the trap to occur.

The Intel Fortran compiler generates machine code to support these requirements in accordance with your selected \(/\text{fpe}\) option setting. In other words, the generated code must support the trapping mode. You can see this by compiling a simple test program and look at the machine code listing with \(/\text{fpe}:0\) first, then \(/\text{fpe}:3\). There are no \(\text{fwait}\) instructions in the \(/\text{fpe}:3\) code. Even if you replace the default run-time exception handler with your own handler, you may still want to compile with \(/\text{fpe}:0\) to generate code that supports trapping.

**Floating-Point Exceptions in Fortran DLL Applications**

In a DLL, there is no main Fortran program (unless you have written your main program in Fortran), so there is no automatic calling of run-time routines to initialize the environment. Even if you select \(/\text{fpe}:0\), there is nothing that causes the run-time system to unmask traps in the hardware so you won’t see traps. You will continue to see the hardware generated default IEEE results (Nan’s, Infinities, and denormalized numbers in your computations). The generated code will still do its part by supplying the \(\text{fwait}\) instructions, and so on, but unless the traps are unmasked somehow, no traps will occur. You can use \(\text{SET\_CONTROL\_FP\_Q}\) or \(\text{FOR\_SET\_FPE}\) to unmask traps in the floating-point control word.
There is also no default exception handling in a DLL. The main application that calls the DLL must provide this, or the code in the DLL must provide something when it is called. Since underflow processing (fixup to 0, and so on) is done by the default Fortran run-time system handler, a DLL won't have that feature automatically.

A typical strategy is to compile with `/fpe:0`, but only unmask floating divide-by-zero, floating overflow, and floating invalid traps in the floating-point control word. By leaving floating-point underflow traps masked, the hardware will continue to provide gradual underflow, but other floating-point exceptions will generate traps, which the user then handles as desired.

**Floating-Point Exceptions in Fortran Windows Applications**

In a Fortran Windows application, the situation is similar to a Fortran DLL application. You define a WinMain routine in your Fortran code as the main entry point for your application. The Fortran run-time system does not define the main routine as it does in a Fortran console or Fortran QuickWin (or Standard Graphics) application. Your code is not protected by the default handler and the default run-time initialization routines are not called.
Overview: Understanding IEEE Floating-point Standard

This version of Intel® Compiler uses a close approximation to the IEEE floating-point standard (ANSI/IEEE Std 754-1985, IEEE Standard for Binary Floating-Point Arithmetic, 1985) unless otherwise stated. This standard is common to many microcomputer-based systems due to the availability of fast processors that implement the required characteristics.

This section outlines the characteristics of the standard and its implementation for the Intel Compilers. Except as noted, the description includes both the IEEE standard and the Intel Compiler implementation.

Floating-point Formats

The IEEE Standard 754 specifies values and requirements for floating-point representation (such as base 2). The standard outlines requirements for two formats: basic and extended, and for two word-lengths within each format: single and double.

Intel Fortran supports single-precision format (REAL(4)) and double-precision format (REAL(8)) floating-point numbers. At some levels of optimization, some floating-point numbers are stored in register file format (which equals 1 bit sign, 15 bit exponent, 64 bits of significand rounded to 53 bits), rather than being stored in IEEE single or double precision format. This can affect the values produced by some computations. The compiler option -fp-model (Linux® and Mac OS® X) or /fp (Windows®) can control how floating-point expressions are evaluated, thus leading to more predictable results.

Limitations of Numeric Conversion

The Intel® Fortran floating-point conversion solution is not expected to fulfill all floating-point conversion needs.

For instance, data fields in record structure variables (specified in a STRUCTURE statement) and data components of derived types (TYPE statement) are not converted. When they are later examined as separate fields by the program, they will remain in the binary format they were stored in on disk, unless the program is modified. With EQUIVALENCE statements, the data type of the variable named in the I/O statement is used.
If a program reads an I/O record containing multiple format floating-point fields into a single variable (such as an array) instead of their respective variables, the fields will not be converted. When they are later examined as separate fields by the program, they will remain in the binary format they were stored in on disk, unless the program is modified.

Conversions of the following file structure types are not supported:

- Binary data (FORM='BINARY')
- Formatted data (FORM='FORMATTED')
- Unformatted data (FORM='UNFORMATTED') written by Microsoft Fortran PowerStation or by Intel Fortran with the /fpscomp:ioformat compiler option in effect.

**Special Values**

This topic lists the special values of IEEE floating-point REALs that the Intel® Compiler supports and provides a brief description of each of them.

**Signed Zero**

Intel Fortran treats zero as signed by default. The sign of zero is the same as the sign of a nonzero number. If you use the intrinsic function `SIGN` with zero as the second argument, the sign of the zero will be transferred. Comparisons, however, consider +0 to be equal to -0.

A signed zero is useful in certain numerical analysis algorithms but in most applications the sign of zero is invisible. -0.0 is accepted as formatted input but is printed as formatted output only when the `-assume minus0` compiler option is used.

**Denormalized Numbers**

Denormalized numbers (denormals) fill the gap between the smallest positive normalized number and the smallest negative number. Otherwise only (+/-) 0 occurs in that interval. Denormalized numbers extend the range of computable results by allowing for gradual underflow.

Systems based on the IA-32 architecture support the Denormal Operand status flag, which when set, means that at least one of the input operands to a floating-point operation is a denormal. The Underflow status flag is set when a number loses precision and becomes a denormal.

Denormalized values can be read and printed with formatted I/O.
Signed Infinity

Infinities are the result of arithmetic in the limiting case of operands with arbitrarily large magnitude. They provide a way to continue when an overflow occurs. The sign of an infinity is simply the sign you obtain for a finite number in the same operation as the finite number approaches an infinite value.

By retrieving the status flags, you can differentiate between an infinity that results from an overflow and one that results from division by zero. Intel® Compiler treats infinity as signed by default. +Infinity and -Infinity are accepted as formatted input and those strings are printed on/as formatted output.

Not a Number

Not a Number (NaN) results from an invalid operation. For instance 0/0 and SQRT(-1) result in NaN. In general, an operation involving a NaN produces another NaN. Because the fraction of a NaN is unspecified, there are many possible NaNs. The Intel® processor treats all NaNs identically but provides two different types of NaNs:

- **Signaling NaN**: has an initial fraction bit of 0 (zero), which usually raises an invalid exception when used in an operation.
- **Quiet NaN**: has an initial fraction bit of 1.

The floating-point hardware changes a signaling NaN into a quiet NaN during many arithmetic operations, including the assignment operation. An invalid exception may be raised but the resulting floating-point value will be a quiet NaN. An operation may raise an invalid exception and return a signaling NaN but if the exception is not trapped, the signaling NaN may be turned into a quite NaN by subsequent processing.

Fortran binary and unformatted input and output do not change the internal representations of the values as they are handled. Therefore, signaling and quiet NaNs may be read into real data and output to files in binary form. ‘NaN’ is accepted as formatted input and results in a quiet NaN. ‘NaN’ is printed by formatted output for both signaling and quiet NaNs.
Representing Floating-point Numbers

Floating-point Representation

The Fortran numeric environment is flexible, which helps make Fortran a strong language for intensive numerical calculations. The Fortran standard purposely leaves the precision of numeric quantities and the method of rounding numeric results unspecified. This allows Fortran to operate efficiently for diverse applications on diverse systems.

Computations on real numbers may not yield what you expect. This happens because the hardware must represent numbers in a finite number of bits.

There are several effects of using finite floating-point numbers. The hardware is not able to represent every real number exactly, but must approximate exact representations by rounding or truncating to finite length. In addition, some numbers lie outside the range of representation of the maximum and minimum exponents and can result in calculations that underflow and overflow. As an example of one consequence, finite precision produces many numbers that, although non-zero, behave in addition as zero.

You can minimize the effects of finite representation with programming techniques; for example, by not using floating-point numbers in LOGICAL comparisons or by giving them a tolerance (for example, IF (ABS(x-10.0) <= 0.001)), and by not attempting to combine or compare numbers that differ by more than the number of significant bits.

Floating-point numbers approximate real numbers with a finite number of bits. The bits are calculated as shown in the following formula. The representation is binary, so the base is 2. The bits $b_n$ represent binary digits (0 or 1). The precision $P$ is the number of bits in the nonexponential part of the number (the significand), and $E$ is the exponent. With these parameters, binary floating-point numbers approximate real numbers with the values:

$(-1)^s \cdot b_0b_1b_2...b_{p-1} \cdot 2^E$

where $s$ is 0 or 1 (+ or -), and $E_{\text{min}} \leq E \leq E_{\text{max}}$

The following table gives the standard values for these parameters for single, double, and quad (extended precision) formats and the resulting bit widths for the sign, the exponent, and the full number.

Parameters for IEEE* Floating-Point Formats

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Single</th>
<th>Double</th>
<th>Quad or Extended Precision (IEEE_X)*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign width in bits</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
The actual number of bits needed to represent the precisions 24, 53, and 113 is therefore 23, 52, and 112, respectively, because $b_0$ is chosen to be 1 implicitly.

A bias is added to all exponents so that only positive integer exponents occur. This expedites comparisons of exponent values. The stored exponent is actually:

\[ e = E + \text{bias} \]

# Functions that Return Numeric Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Argument/Function Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIGITS</td>
<td>DIGITS(x). Returns number of significant digits for data of the same type as x.</td>
<td>x: Integer or Real result: INTEGER(4)</td>
</tr>
<tr>
<td>EPSILON</td>
<td>EPSILON(x). Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as x.</td>
<td>x: Real result: same type as x</td>
</tr>
<tr>
<td>EXPONENT</td>
<td>EXPONENT(x). Returns the exponent part of the representation of x.</td>
<td>x: Real result: INTEGER(4)</td>
</tr>
<tr>
<td>FRACTION</td>
<td>FRACTION(x). Returns the fractional part (significand) of the representation of x.</td>
<td>x: Real result: same type as x</td>
</tr>
<tr>
<td>HUGE</td>
<td>HUGE(x). Returns largest number that can be represented by data of type x.</td>
<td>x: Integer or Real result: same type as x</td>
</tr>
<tr>
<td>MAXEXPONENT</td>
<td>MAXEXPONENT(x). Returns the largest positive decimal exponent for data of the same type as x.</td>
<td>x: Real result: INTEGER(4)</td>
</tr>
<tr>
<td>MINEXPONENT</td>
<td>MINEXPONENT(x). Returns the largest negative decimal exponent for data of the same type as x.</td>
<td>x: Real result: INTEGER(4)</td>
</tr>
<tr>
<td>NEAREST</td>
<td>NEAREST(x, s). Returns the nearest different machine representable number to x in the direction of the sign of s.</td>
<td>x: Real s: Real and not zero result: same type as x.</td>
</tr>
<tr>
<td>PRECISION</td>
<td>PRECISION(x). Returns the number of significant digits for data of the same type as x.</td>
<td>x: Real or Complex result: INTEGER(4)</td>
</tr>

<tr>
<td>RANGE</td>
<td>RANGE(x). Returns the decimal exponent range for data of the same type as x.</td>
<td>x: Integer, Real or Complex result: INTEGER(4)</td>
</tr>
<tr>
<td>RRSPACING</td>
<td>RRSPACING(x). Returns the reciprocal of the relative spacing of numbers near x.</td>
<td>x: Real result: same type as x</td>
</tr>
<tr>
<td>SCALE</td>
<td>SCALE(x, i). Multiplies x by 2 raised to the power of i.</td>
<td>x: Real i: Integer result: same type as x</td>
</tr>
<tr>
<td>SET_EXPONENT</td>
<td>SET_EXPONENT(x, i). Returns a number whose fractional part is x and whose exponential part is i.</td>
<td>x: Real i: Integer result: same type as x</td>
</tr>
<tr>
<td>SPACING</td>
<td>SPACING(x). Returns the absolute spacing of numbers near x.</td>
<td>x: Real result: same type as x</td>
</tr>
<tr>
<td>TINY</td>
<td>TINY(x). Returns smallest positive number that can be represented by data of type x.</td>
<td>x: Real result: same type as x</td>
</tr>
</tbody>
</table>

**ULPs, Relative Error, and Machine Epsilon**

ULP, Relative Error, and Machine Epsilon are terms that describe the magnitude of rounding error. A floating-point approximation to a real constant or to a computed result may err by as much as 1/2 unit in the last place (the $b_{p-1}$ bit). The abbreviation $ULP$ represents the measure "unit in the last place." Another measure of the rounding error uses the relative error, which is the difference between the exact number and its approximation divided by the exact number. The relative error that corresponds to 1/2 $ULP$ is bounded by:

$$1/2 \cdot 2^{-p} \leq 1/2 \cdot ULP \leq 2^{-p}$$

The upper bound $EPS = 2^{-p}$, the machine epsilon, is commonly used in discussions of rounding errors because it expresses the smallest floating-point number that you can add to 1.0 with a result that does not round to 1.0.

Native IEEE Floating-point Representation

Overview: Native IEEE* Floating-point Representations

The REAL(4) (IEEE* S_floating), REAL(8) (IEEE T_floating), and REAL(16) (IEEE-style X_floating) formats are stored in standard little endian IEEE binary floating-point notation. (See IEEE Standard 754 for additional information about IEEE binary floating point notation.) COMPLEX() formats use a pair of REAL values to denote the real and imaginary parts of the data.

All floating-point formats represent fractions in sign-magnitude notation, with the binary radix point to the right of the most-significant bit. Fractions are assumed to be normalized, and therefore the most-significant bit is not stored (this is called "hidden bit normalization"). This bit is assumed to be 1 unless the exponent is 0. If the exponent equals 0, then the value represented is denormalized (subnormal) or plus or minus zero.

Intrinsic REAL kinds are 4 (single precision), 8 (double precision), and 16 (extended precision), such as REAL(KIND=4) for single-precision floating-point data. Intrinsic COMPLEX kinds are also 4 (single precision), 8 (double precision), and 16 (extended precision).

To obtain the kind of a variable, use the KIND intrinsic function. You can also use a size specifier, such as REAL*4, but be aware this is an extension to the Fortran 2003 standard.

If you omit certain compiler options, the default sizes for REAL and COMPLEX data declarations are as follows:

- For REAL data declarations without a kind parameter (or size specifier), the default size is REAL (KIND=4) (same as REAL*4).
- For COMPLEX data declarations without a kind parameter (or size specifier), the default data size is COMPLEX (KIND=4) (same as COMPLEX*8).

To control the size of all REAL or COMPLEX declarations without a kind parameter, use the /real_size:64 (or /4R8) or /real_size:128 (or /4R16) options; the default is /real_size:32.

You can explicitly declare the length of a REAL or a COMPLEX declaration using a kind parameter, or specify DOUBLE PRECISION or DOUBLE COMPLEX. To control the size of all DOUBLE PRECISION and DOUBLE COMPLEX declarations, use the /double_size:128 (or /Qautodouble) option; the default is /double_size:64.

REAL(KIND=4) (REAL) Representation

REAL(4) (same as REAL(KIND=4)) data occupies 4 contiguous bytes stored in IEEE S_floating format. Bits are labeled from the right, 0 through 31, as shown below.

REAL(4) Floating-Point Data Representation
The form of REAL(4) data is sign magnitude, with bit 31 the sign bit (0 for positive numbers, 1 for negative numbers), bits 30:23 a binary exponent in excess 127 notation, and bits 22:0 a normalized 24-bit fraction including the redundant most-significant fraction bit not represented.

The value of data is in the approximate range: 1.17549435E-38 (normalized) to 3.40282347E38. The IEEE denormalized (subnormal) limit is 1.40129846E-45. The precision is approximately one part in 2**23; typically 7 decimal digits.

**REAL(KIND=8) (DOUBLE PRECISION) Representation**

REAL(8) (same as REAL(KIND=8)) data occupies 8 contiguous bytes stored in IEEE T_floating format. Bits are labeled from the right, 0 through 63, as shown below.

**REAL(8) Floating-Point Data Representation**

```
 63  62  52  51  0
 SIGN | EXPONENT | FRACTION :A
```

The form of REAL(8) data is sign magnitude, with bit 63 the sign bit (0 for positive numbers, 1 for negative numbers), bits 62:52 a binary exponent in excess 1023 notation, and bits 51:0 a normalized 53-bit fraction including the redundant most-significant fraction bit not represented.

The value of data is in the approximate range: 2.2250738585072013D-308 (normalized) to 1.7976931348623158D308. The IEEE denormalized (subnormal) limit is 4.94065645841246544D-324. The precision is approximately one part in 2**52; typically 15 decimal digits.

**REAL(KIND=16) Representation**

REAL(16) (same as REAL(KIND=16)) data occupies 16 contiguous bytes stored in IEEE-style X_floating format. Bits are labeled from the right, 0 through 127, as shown below.

```
 31  30  23  22  0
 SIGN | EXPONENT | FRACTION :A
```

The form of REAL(16) data is sign magnitude, with bit 31 the sign bit (0 for positive numbers, 1 for negative numbers), bits 30:23 a binary exponent in excess 127 notation, and bits 22:0 a normalized 24-bit fraction including the redundant most-significant fraction bit not represented.

The value of data is in the approximate range: 1.17549435E-38 (normalized) to 3.40282347E38. The IEEE denormalized (subnormal) limit is 1.40129846E-45. The precision is approximately one part in 2**23; typically 7 decimal digits.
The form of REAL(16) data is sign magnitude, with bit 127 the sign bit (0 for positive numbers, 1 for negative numbers), bits 126:112 a binary exponent in excess 16383 notation, and bits 111:0 a normalized 113-bit fraction including the redundant most-significant fraction bit not represented.

The value of data is in the approximate range:

6.4751751194380251109244389582276465524996Q-4966 to
1.189731495357231765085759326628007016196477Q4932. Unlike other floating-point formats, there is little if any performance penalty from using denormalized extended-precision numbers. This is because accessing denormalized REAL (KIND=16) numbers does not result in an arithmetic trap (the extended-precision format is emulated in software). The smallest normalized number is 3.362103143112093506262677817321753Q-4932.

The precision is approximately one part in 2**112 or typically 33 decimal digits.

**COMPLEX(KIND=4) (COMPLEX) Representation**

COMPLEX(4) (same as COMPLEX(KIND=4) and COMPLEX*8) data is 8 contiguous bytes containing a pair of REAL(4) values stored in IEEE S_floating format. The low-order 4 bytes contain REAL(4) data that represents the real part of the complex number. The high-order 4 bytes contain REAL(4) data that represents the imaginary part of the complex number, as shown below.

**COMPLEX(4) Floating-Point Data Representation**

The limits and underflow characteristics for REAL(4) apply to the two separate real and imaginary parts of a COMPLEX(4) number. Like REAL(4) numbers, the sign bit representation is 0 (zero) for positive numbers and 1 for negative numbers.
COMPLEX(KIND=8) (DOUBLE COMPLEX) Representation

COMPLEX(8) (same as COMPLEX(KIND=8) and COMPLEX*16) data is 16 contiguous bytes containing a pair of REAL(8) values stored in IEEE T_floating format. The low-order 8 bytes contain REAL(8) data that represents the real part of the complex data. The high-order 8 bytes contain REAL(8) data that represents the imaginary part of the complex data, as shown below.

COMPLEX(8) Floating-Point Data Representation

<table>
<thead>
<tr>
<th>REAL PART</th>
<th>IMAGINARY PART</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGN</td>
<td>EXPONENT</td>
</tr>
<tr>
<td>63</td>
<td>52</td>
</tr>
</tbody>
</table>

The limits and underflow characteristics for REAL(8) apply to the two separate real and imaginary parts of a COMPLEX(8) number. Like REAL(8) numbers, the sign bit representation is 0 (zero) for positive numbers and 1 for negative numbers.

COMPLEX(KIND=16) Representation

COMPLEX(16) (same as COMPLEX(KIND=16) or COMPLEX*32) data is 32 contiguous bytes containing a pair of REAL(16) values stored in IEEE-style X_floating format. The low-order 16 bytes contain REAL(16) data that represents the real part of the complex data. The high-order 16 bytes contain REAL(8) data that represents the imaginary part of the complex data, as shown below.

<table>
<thead>
<tr>
<th>REAL PART</th>
<th>IMAGINARY PART</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGN</td>
<td>EXPONENT</td>
</tr>
<tr>
<td>127</td>
<td>126</td>
</tr>
</tbody>
</table>

The limits and underflow characteristics for REAL(16) apply to the two separate real and imaginary parts of a COMPLEX(16) number. Like REAL(16) numbers, the sign bit representation is 0 (zero) for positive numbers and 1 for negative numbers.
Handling Exceptions and Errors

Loss of Precision Errors

If a real number is not exactly one of the representable floating-point numbers, then the nearest floating-point number must represent it. The rounding error is the difference between the exact real number and its nearest floating-point representation. If the rounding error is non-zero, the rounded floating-point number is called \textit{inexact}.

Normally, calculations proceed when an inexact value results. Almost any floating-point operation can produce an inexact result. The rounding mode (round up, round down, round nearest, truncate) is determined by the floating-point control word.

If an arithmetic operation results in a floating-point number that cannot be represented in a specific data type, the operation may produce a special value: signed zero, signed infinity, NaN, or a denormal. Numbers that have been rounded to an exactly representable floating-point number also result in a special value. Special-value results are a limiting case of the arithmetic operation involved. Special values can propagate through your arithmetic operations without causing your program to fail, and often provide usable results.

If an arithmetic operation results in an exception, the operation can cause an underflow or overflow:

- Underflow occurs when an arithmetic result is too small for the math processor to handle. Depending on the setting of the \texttt{/fpe} compiler option, underflows are set to zero (they are usually harmless) or they are left as is (denormalized).
- Overflow occurs when an arithmetic result is too large for the math processor to handle. Overflows are more serious than underflows, and may indicate an error in the formulation of a problem (for example, unintended exponentiation of a large number by a large number). Overflows generally produce an appropriately signed infinity value. (This depends on the rounding mode as per the IEEE standard.)

An arithmetic operation can also throw the following exceptions: divide-by-zero exception, an invalid exception, and an inexact exception.

You can select how exceptions are handled by setting the floating-point control word.

See Also

- Handling Exceptions and Errors
- Special Values
Rounding Errors

Although the rounding error for one real number might be acceptably small in your calculations, at least two problems can arise because of it. If you test for exact equality between what you consider to be two exact numbers, the rounding error of either or both floating-point representations of those numbers may prevent a successful comparison and produce spurious results. Also, when you calculate with floating-point numbers the rounding errors may accumulate to a meaningful loss of numerical significance.

Carefully consider the numerics of your solution to minimize rounding errors or their effects. You might benefit from using double-precision arithmetic or restructuring your algorithm, or both. For instance, if your calculations involve arrays of linear data items, you might reduce the loss of numerical significance by subtracting the mean value of each array from each array element and by normalizing each element of such an array to the standard deviation of the array elements.

The following code segment can execute differently on various systems and produce varying results for \( n \), \( x \), and \( s \). It also produces different results if you use the `-fp-model precise` (Linux* and Mac OS* X) or `/fp:precise` (Windows*; systems), or `-fp-model fast` (Linux and Mac OS X) or `/fp:fast` (Windows) compiler options. Rounding error accumulates in \( x \) because the floating-point representation of 0.2 is inexact, then accumulates in \( s \), and affects the final value for \( n \):

```fortran
INTEGER n
REAL s, x
n = 0
s = 0.0
x = 0.0
1 n = n + 1
x = x + 0.2
s = s + x
IF ( x .LE. 10. ) GOTO 1 ! Will you get 51 cycles?
WRITE(*,*) 'n = ', n, '; x = ', x, '; s = ', s
```

This example illustrates a common coding problem: carrying a floating-point variable through many successive cycles and then using it to perform an IF test. This process is common in numerical integration. There are several remedies. You can compute \( x \) and \( s \) as multiples of an integer index, for example, replacing the statement that increments \( x \) with \( x = n * 0.2 \)
to avoid round-off accumulation. You might test for completion on the integer index, such as
IF (n <= 50) GOTO 1, or use a DO loop, such as DO n= 1,51. If you must test on the real
variable that is being cycled, use a realistic tolerance, such as IF (x <= 10.001).

Floating-point arithmetic does not always obey the standard rules of algebra exactly. Addition
is not precisely associative when round-off errors are considered. You can use parentheses to
express the exact evaluation you require to compute a correct, accurate answer, provided you
use a switch such as /fp:precise (on Windows systems) or -fp-model precise (on Linux
or MacOS X systems), or /assume:protect_parens (on Windows systems) or -assume
protect_parens (on Linux or MacOS X systems). This is recommended when you specify
optimization for your generated code, since associativity may otherwise be unpredictable.

The expressions (x + y) + z and x + (y + z) can give unequal results in some cases.

The compiler uses the default rounding mode (round-to-nearest) during compilation. The
compiler performs more compile-time operations that eliminate runtime operations as the
optimization level increases. If you set rounding mode to a different setting (other than
round-to-nearest), that rounding mode is used only if that computation is performed at runtime.
If you want to force computations to be performed at runtime, use the -fp-model strict
(Linux or MacOS) or /fp:strict (Windows) option.

- Additional Language Features
- Additional Character Sets
- Data Representation Models
- Run-Time Library Routines
• Summary of Language Extensions
• A to Z Reference
• Glossary
This document contains the complete description of the Intel® Fortran programming language, which includes Fortran 95, Fortran 90, and many Fortran 2003 language features. It contains information on language syntax and semantics, on adherence to various Fortran standards, and on extensions to those standards.

This manual is intended for experienced applications programmers who have a basic understanding of Fortran concepts and the Fortran 95/90 language.

Some familiarity with your operating system is helpful. This manual is not a Fortran or programming tutorial.

This manual contains the full content of what originally appeared in the Language Reference and Libraries Reference PDF files. However, the library routines described in the Libraries Reference PDF file are now described within the A to Z Reference.

This document covers the following topics:

- **Conformance, Compatibility, and Fortran 2003 Features**
  This topic describes conformance with language standards, compatibility with other Fortran languages, and it contains a summary of Fortran 2003 features.

- **Program Structure, Characters, and Source Forms**
  This topic describes program structure, the Fortran 95/90 character set, and source forms.

- **Data Types, Constants, and Variables**
  This topic describes language standards, language compatibility, and Fortran 95/90 features.

- **Expressions and Assignment Statements**
  This topic describes Fortran expressions and assignment statements, which are used to define or redefine variables.

- **Specification Statements**
  This topic describes specification statements, which are used to declare the attributes of data objects.

- **Dynamic Allocation**
  This topic describes statements used in dynamic allocation: ALLOCATE, DEALLOCATE, and NULLIFY.

- **Execution Control**
  This topic describes constructs and statements that can transfer control within a program.

- **Program Units and Procedures**
  This topic describes program units (including modules), subroutines and functions, and procedure interfaces.
• **Intrinsic Procedures**
  This topic describes argument keywords used in intrinsic procedures and provides an overview of intrinsic procedures.

• **Data Transfer I/O Statements**
  This topic describes data transfer input/output (I/O) statements.

• **I/O Formatting**
  This topic describes the rules for I/O formatting.

• **File Operation I/O Statements**
  This topic describes auxiliary I/O statements you can use to perform file operations.

• **Compilation Control Statements**
  This topic describes compilation control statements: INCLUDE and OPTIONS.

• **Directive Enhanced Compilation**
  This topic describes general and parallel compiler directives.

• **Scope and Association**
  This topic describes scope, which refers to the area in which a name is recognized, and association, which is the language concept that allows different names to refer to the same entity in a particular region of a program.

• **Deleted and Obsolescent Language Features**
  This topic describes deleted features in Fortran 95 and obsolescent language features in Fortran 95 and Fortran 90.

• **Additional Language Features**
  This topic describes some statements and language features supported for programs written in older versions of Fortran.

• **Additional Character Sets**
  This topic describes the additional character sets available on Windows*, Linux*, and Mac OS* X systems.

• **Data Representation Models**
  This topic describes data representation models for numeric intrinsic functions.

• **Run-Time Library Routines**
  This topic summarizes the many run-time library routines.

• **Summary of Language Extensions**
  This topic summarizes Intel Fortran extensions to the Fortran 95 Standard.

• **A to Z Reference**
This topic contains language summary tables and descriptions of all Intel® Fortran statements, intrinsics, directives, and module library routines, which are listed in alphabetical order.

- **Glossary**
  This topic contains abbreviated definitions of some commonly used terms in this manual.

For details on the features of the compilers, see your guide to *Building Applications*. For details on how to improve the run-time performance of Fortran programs, see your guide to *Optimizing Applications*. For details on floating-point support, see your guide to Floating-point Operations. For details on compiler options, see your *Compiler Options* reference.

For information on conventions used in this document, see *Conventions*.

For more information on Fortran 2003 features in this release, see *Fortran 2003 Features*.

### New Language Features

The major new features for this release are as follows:

- **OpenMP* Fortran directive TASK**
  The TASK directive defines a task region. For more information, see *TASK*.

- **OpenMP* Fortran directive TASKWAIT**
  The TASKWAIT directive specifies a wait on the completion of child tasks generated since the beginning of the current task. For more information, see *TASKWAIT*.

- **OpenMP* Fortran directive clause SCHEDULE (AUTO)**
  The AUTO setting delegates the scheduling decision until compile time or run time. The schedule is processor dependent. For more information, see SCHEDULE in the DO directive.

- **VECTOR TEMPORAL directive**
  The VECTOR TEMPORAL directive tells the compiler to use temporal (that is, non-streaming) stores. For more information, see VECTOR TEMPORAL and VECTOR NONTEMPORAL.

- **VECTOR NONTEMPORAL directive now allows variables**
  VECTOR NONTEMPORAL directs the compiler to use non-temporal (that is, streaming) stores. It now allows variables as optional memory references. For more information, see VECTOR TEMPORAL and VECTOR NONTEMPORAL.

- **UNROLL_AND_JAM and NOUNROLL_AND_JAM directives**
  The UNROLL_AND_JAM and NOUNROLL_AND_JAM directives enable or disable loop unrolling and jamming. For more information, see UNROLL_AND_JAM and NOUNROLL_AND_JAM.

For more information on Fortran 2003 features, see *Fortran 2003 Features*. 
For information on new compiler options in this release, see New Options in the *Compiler Options* reference.
Conformance, Compatibility, and Fortran 2003 Features

Fortran 95 includes Fortran 90 and most features of FORTRAN 77. Fortran 90 is a superset that includes FORTRAN 77. Intel Fortran fully supports the Fortran 95, Fortran 90, and FORTRAN 77 Standards.

Language Standards Conformance

The ANSI committee X3J3 is currently answering questions of interpretation of Fortran 95 and Fortran 90 language features. Any answers given by the ANSI committee that are related to features implemented in Intel Fortran may result in changes in future releases of the Intel Fortran compiler, even if the changes produce incompatibilities with earlier releases of Intel Fortran.

Intel Fortran provides a number of extensions to the Fortran 95 Standard. In the language reference, extensions are displayed in this color.

Language Compatibility

Intel Fortran is highly compatible with Compaq\* Fortran 77 on supported systems, and it is substantially compatible with PDP-11\* and VAX\* FORTRAN 77.

Fortran 2003 Features

The following Fortran 2003 features are new in this release:

- Enumerators
- Type extension (not polymorphic)
- Allocatable scalar variables (not deferred-length character)
- ERRMSG keyword for ALLOCATE and DEALLOCATE

\(^1\) This is the same as International Standards Organization standard ISO/IEC 1539-1:1997 (E).
\(^2\) This is the same as International Standards Organization standard ISO/IEC 1539:1991 (E).
- SOURCE= keyword for ALLOCATE
- Character arguments for MAX, MIN, MAXVAL, MINVAL, MAXLOC, and MINLOC
- Intrinsic modules IEEE_EXCEPTIONS, IEEE_ARITHMETIC and IEEE_FEATURES
- ASSOCIATE construct
- PROCEDURE declaration
- Procedure pointers
- ABSTRACT INTERFACE
- PASS and NOPASS attributes
- Structure constructors with component names and default initialization
- Array constructors with type and character length specifications
- I/O keywords BLANK, DELIM, ENCODING, IOMSG, PAD, ROUND, SIGN, and SIZE
- Format edit descriptors DC, DP, RD, RC, RN, RP, RU, and RZ

The following Fortran 2003 features are also supported:
- RECORDTYPE setting STREAM_CRLF
- A file can be opened for stream access (ACCESS='STREAM')
- Specifier POS can be specified in an INQUIRE, READ, or WRITE statement
- BIND attribute and statement
- Language binding can be specified in a FUNCTION or SUBROUTINE statement, or when defining a derived type
- IS_IOSTAT_END intrinsic function
- IS_IOSTAT_EOL intrinsic function
- INTRINSIC and NONINTRINSIC can be specified for modules in USE statements
- ASYNCHRONOUS attribute and statement
- VALUE attribute and statement
- Specifier ASYNCHRONOUS can be specified in an OPEN, INQUIRE, READ, or WRITE statement
- An ID can be specified for a pending data transfer operation
- FLUSH statement
- WAIT statement
- IMPORT statement
- NEW_LINE intrinsic function
- SELECTED_CHAR_KIND intrinsic function
Intrinsic modules ISO_C_BINDING and ISO_FORTRAN_ENV
MEMORYTOUCH compiler directive
Specifiers ID and PENDING can be specified in an INQUIRE statement
User-defined operators can be renamed in USE statements
MOVE_ALLOC intrinsic subroutine
PROTECTED attribute and statement
Pointer objects can have the INTENT attribute
GET_COMMAND intrinsic
GET_COMMAND_ARGUMENT intrinsic
COMMAND_ARGUMENT_COUNT intrinsic
GET_ENVIRONMENT_VARIABLE intrinsic
Allocatable components of derived types
Allocatable dummy arguments
Allocatable function results
VOLATILE attribute and statement
Names of length up to 63 characters
Statements up to 256 lines
A named PARAMETER constant may be part of a complex constant
In all I/O statements, the following numeric values can be of any kind: UNIT=, IOSTAT=
The following OPEN numeric values can be of any kind: RECL=
The following READ and WRITE numeric values can be of any kind: REC=, SIZE=
The following INQUIRE numeric values can be of any kind: NEXTREC=, NUMBER=, RECL=, SIZE=
Recursive I/O is allowed when the new I/O being started is internal I/O that does not modify any internal file other than its own
IEEE infinities and Nans are displayed by formatted output as specified by Fortran 2003
In an I/O format, the comma after a P edit descriptor is optional when followed by a repeat specifier
The following intrinsics take an optional KIND= argument: ACHAR, COUNT, IACHAR, ICHAR, INDEX, LBOUND, LEN, LEN_TRIM, MAXLOC, MINLOC, SCAN, SHAPE, SIZE, UBOUND, VERIFY
Square brackets [ ] are permitted to delimit array constructors instead of (/ /)
The Fortran character set has been extended to contain the 8-bit ASCII characters ~ \ [ ] ^ { } | # @

Program Structure, Characters, and Source Forms

This section contains information on the following topics:

- An overview of *program structure*, including general information on statements and names
- Character sets
- Source forms

**Program Structure**

A Fortran program consists of one or more program units. A *program unit* is usually a sequence of statements that define the data environment and the steps necessary to perform calculations; it is terminated by an END statement.

A program unit can be either a main program, an external subprogram, a module, or a block data program unit. An executable program contains one main program, and, optionally, any number of the other kinds of program units. Program units can be separately compiled.

An *external subprogram* is a function or subroutine that is not contained within a main program, a module, or another subprogram. It defines a procedure to be performed and can be invoked from other program units of the Fortran program. Modules and block data program units are not executable, so they are not considered to be procedures. (Modules can contain module procedures, though, which are executable.)

*Modules* contain definitions that can be made accessible to other program units: data and type definitions, definitions of procedures (called *module subprograms*), and *procedure interfaces*. Module subprograms can be either functions or subroutines. They can be invoked by other module subprograms in the module, or by other program units that access the module.

A *block data program unit* specifies initial values for data objects in named common blocks. In Fortran 95/90, this type of program unit can be replaced by a module program unit.

Main programs, external subprograms, and module subprograms can contain *internal subprograms*. The entity that contains the internal subprogram is its *host*. Internal subprograms can be invoked only by their host or by other internal subprograms in the same host. Internal subprograms must not contain internal subprograms.

The following sections discuss *Statements, Names, and Keywords*. 
Statements

Program statements are grouped into two general classes: executable and nonexecutable. An executable statement specifies an action to be performed. A nonexecutable statement describes program attributes, such as the arrangement and characteristics of data, as well as editing and data-conversion information.

Order of Statements in a Program Unit

The following figure shows the required order of statements in a Fortran program unit. In this figure, vertical lines separate statement types that can be interspersed. For example, you can intersperse DATA statements with executable constructs.

Horizontal lines indicate statement types that cannot be interspersed. For example, you cannot intersperse DATA statements with CONTAINS statements.
PUBLIC and PRIVATE statements are only allowed in the scoping units of modules. In Fortran 95/90, NAMELIST statements can appear only among specification statements. However, Intel® Fortran allows them to also appear among executable statements.

The following table shows other statements restricted from different types of scoping units.
Statements Restricted in Scoping Units

<table>
<thead>
<tr>
<th>Scoping Unit</th>
<th>Restricted Statements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main program</td>
<td>ENTRY, IMPORT, and RETURN statements</td>
</tr>
<tr>
<td>Module¹</td>
<td>ENTRY, FORMAT, IMPORT, OPTIONAL, and INTENT statements, statement functions, and executable statements</td>
</tr>
<tr>
<td>Block data program unit</td>
<td>CONTAINS, ENTRY, IMPORT, and FORMAT statements, interface blocks, statement functions, and executable statements</td>
</tr>
<tr>
<td>Internal subprogram</td>
<td>CONTAINS, IMPORT, and ENTRY statements</td>
</tr>
<tr>
<td>Interface body</td>
<td>CONTAINS, DATA, ENTRY, IMPORT², SAVE, and FORMAT statements, statement functions, and executable statements</td>
</tr>
</tbody>
</table>

¹ The scoping unit of a module does not include any module subprograms that the module contains.

² An IMPORT statement can appear only in the interface-body of an INTERFACE block.

- Program Structure
- Scope

Names

Names identify entities within a Fortran program unit (such as variables, function results, common blocks, named constants, procedures, program units, namelist groups, and dummy arguments). In FORTRAN 77, names were called "symbolic names".

A name can contain letters, digits, underscores (_), and the dollar sign ($) special character. The first character must be a letter or a dollar sign.

In Fortran 95/90, a name can contain up to 31 characters. Intel® Fortran allows names up to 63 characters.

The length of a module name (in MODULE and USE statements) may be restricted by your file system.
NOTE. Be careful when defining names that contain dollar signs. A dollar sign can be a symbol for command or symbol substitution in various shell and utility commands.

In an executable program, the names of the following entities are global and must be unique in the entire program:

- Program units
- External procedures
- Common blocks
- Modules

Examples

The following examples demonstrate valid and invalid names

**Table 520: Valid Names**

- NUMBER
- FIND_IT
- X

**Table 521: Invalid Names**

- 5Q Begins with a numeral.
- B.4 Contains a special character other than _ or $.
- _WRONG Begins with an underscore.

The following are all valid examples of using names:

- INTEGER (SHORT) K !K names an integer variable
- SUBROUTINE EXAMPLE !EXAMPLE names the subroutine
- LABEL: DO I = 1,N !LABEL names the DO block
Keywords

A keyword can either be a part of the syntax of a statement (statement keyword), or it can be the name of a dummy argument (argument keyword). Examples of statement keywords are WRITE, INTEGER, DO, and OPEN. Examples of argument keywords are arguments to the intrinsic functions.

In the intrinsic function UNPACK \((vector, mask, field)\), for example, \(vector\), \(mask\), and \(field\) are argument keywords. They are dummy argument names, and any variable may be substituted in their place. Dummy argument names and real argument names are discussed in Program Units and Procedures.

Keywords are not reserved. The compiler recognizes keywords by their context. For example, a program can have an array named IF, read, or Goto, even though this is not good programming practice. The only exception is the keyword PARAMETER. If you plan to use variable names beginning with PARAMETER in an assignment statement, you need to use compiler option altparam.

Using keyword names for variables makes programs harder to read and understand. For readability, and to reduce the possibility of hard-to-find bugs, avoid using names that look like parts of Fortran statements. Rules that describe the context in which a keyword is recognized are discussed in Program Units and Procedures.

Argument keywords are a feature of Fortran 90 that let you specify dummy argument names when calling intrinsic procedures, or anywhere an interface (either implicit or explicit) is defined. Using argument keywords can make a program more readable and easy to follow. This is described more fully in Program Units and Procedures. The syntax statements in the A-Z Reference show the dummy keywords you can use for each Fortran procedure.

Character Sets

Intel Fortran supports the following characters:

- The Fortran 95/90 character set which consists of the following:
  - All uppercase and lowercase letters (A through Z and a through z)
  - The numerals 0 through 9
  - The underscore (_)
  - The following special characters:
<table>
<thead>
<tr>
<th>Character</th>
<th>Name</th>
<th>Character</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>blank or &lt;Tab&gt;</td>
<td>Blank (space) or tab</td>
<td>:</td>
<td>Colon</td>
</tr>
<tr>
<td>=</td>
<td>Equal sign</td>
<td>!</td>
<td>Exclamation point</td>
</tr>
<tr>
<td>+</td>
<td>Plus sign</td>
<td>&quot;</td>
<td>Quotation mark</td>
</tr>
<tr>
<td>-</td>
<td>Minus sign</td>
<td>%</td>
<td>Percent sign</td>
</tr>
<tr>
<td>*</td>
<td>Asterisk</td>
<td>&amp;</td>
<td>Ampersand</td>
</tr>
<tr>
<td>/</td>
<td>Slash</td>
<td>;</td>
<td>Semicolon</td>
</tr>
<tr>
<td>(</td>
<td>Left parenthesis</td>
<td>&lt;</td>
<td>Less than</td>
</tr>
<tr>
<td>)</td>
<td>Right parenthesis</td>
<td>&gt;</td>
<td>Greater than</td>
</tr>
<tr>
<td>,</td>
<td>Comma</td>
<td>?</td>
<td>Question mark</td>
</tr>
<tr>
<td>.</td>
<td>Period (decimal point)</td>
<td>$</td>
<td>Dollar sign (currency symbol)</td>
</tr>
<tr>
<td>'</td>
<td>Apostrophe</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Other printable characters

Printable characters include the tab character (09 hex), ASCII characters with codes in the range 20(hex) through 7E(hex), and characters in certain special character sets.

Printable characters that are not in the Fortran 95/90 character set can only appear in comments, character constants, Hollerith constants, character string edit descriptors, and input/output records.

Uppercase and lowercase letters are treated as equivalent when used to specify program behavior (except in character constants and Hollerith constants).

Source Forms

Within a program, source code can be in free, fixed, or tab form. Fixed or tab forms must not be mixed with free form in the same source program, but different source forms can be used in different source programs.

All source forms allow lowercase characters to be used as an alternative to uppercase characters.

Several characters are indicators in source code (unless they appear within a comment or a Hollerith or character constant). The following are rules for indicators in all source forms:

- **Comment indicator**
  
  A comment indicator can precede the first statement of a program unit and appear anywhere within a program unit. If the comment indicator appears within a source line, the comment extends to the end of the line.

  An all blank line is also a comment line.

  Comments have no effect on the interpretation of the program unit.

  For more information, see comment indicators in free source form, or fixed and tab source forms.

- **Statement separator**
  
  More than one statement (or partial statement) can appear on a single source line if a statement separator is placed between the statements. The statement separator is a semicolon character (;).

  Consecutive semicolons (with or without intervening blanks) are considered to be one semicolon.

  If a semicolon is the last character on a line, or the last character before a comment, it is ignored.

- **Continuation indicator**
  
  A statement can be continued for more than one line by placing a continuation indicator on the line. Intel Fortran allows at least 511 continuation lines for a fixed or tab source program and at least 255 continuation lines for a free form source program.

  Comments can occur within a continued statement, but comment lines cannot be continued.

  For more information, see continuation indicators in free source form, or fixed and tab source forms.

The following table summarizes characters used as indicators in source forms.
<table>
<thead>
<tr>
<th>Source Item</th>
<th>Indicator</th>
<th>Source Form</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comment</td>
<td>!</td>
<td>All forms</td>
<td>Anywhere in source code</td>
</tr>
<tr>
<td>Comment line</td>
<td>!</td>
<td>Free</td>
<td>At the beginning of the source line</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>!, C, or *</td>
<td>Fixed</td>
<td>In column 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tab</td>
<td>In column 1</td>
</tr>
<tr>
<td>Continuation line</td>
<td>&amp;</td>
<td>Free</td>
<td>At the end of the source line</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Any character except zero or blank</td>
<td>Fixed</td>
<td>In column 6</td>
</tr>
<tr>
<td></td>
<td>Any digit except zero</td>
<td>Tab</td>
<td>After the first tab</td>
</tr>
<tr>
<td>Statement separator</td>
<td>;</td>
<td>All forms</td>
<td>Between statements on the same line</td>
</tr>
<tr>
<td>Statement label</td>
<td>1 to 5 decimal digits</td>
<td>Free</td>
<td>Before a statement</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Fixed</td>
<td>In columns 1 through 5</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tab</td>
<td>Before the first tab</td>
</tr>
<tr>
<td>A debugging statement</td>
<td>D</td>
<td>Fixed</td>
<td>In column 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tab</td>
<td>In column 1</td>
</tr>
</tbody>
</table>

1 If the character appears in a Hollerith or character constant, it is not an indicator and is ignored.
2 For fixed or tab source form, at least 511 continuation lines are allowed. For free source form, at least 255 continuation lines are allowed.
Source form and line length can be changed at any time by using the FREEFORM, NOFREEFORM, or FIXEDFORMLINESIZE directives. The change remains in effect until the end of the file, or until changed again.

You can also select free source form by using compiler option free.

Source code can be written so that it is useable for all source forms.

**Statement Labels**

A *statement label* (or statement number) identifies a statement so that other statements can refer to it, either to get information or to transfer control. A label can precede any statement that is not part of another statement.

A statement label must be one to five decimal digits long; blanks and leading zeros are ignored. An all-zero statement label is invalid, and a blank statement cannot be labeled.

Labeled FORMAT and labeled executable statements are the only statements that can be referred to by other statement. FORMAT statements are referred to only in the format specifier of an I/O statement or in an ASSIGN statement. Two statements within a scoping unit cannot have the same label.

- Free Source Form
- Fixed and Tab Source Forms
- Source Code Useable for All Source Forms
- free compiler option

**Free Source Form**

In free source form, statements are not limited to specific positions on a source line. In Fortran 95/90, a free form source line can contain from 0 to 132 characters. *Intel Fortran* allows the line to be of any length.

Blank characters are significant in free source form. The following are rules for blank characters:

- Blank characters must not appear in lexical tokens, except within a character context. For example, there can be no blanks between the exponentiation operator **. Blank characters can be used freely between lexical tokens to improve legibility.
• Blank characters must be used to separate names, constants, or labels from adjacent keywords, names, constants, or labels. For example, consider the following statements:

```plaintext
INTEGER NUM
GO TO 40
20 DO K=1,8
```

The blanks are required after INTEGER, TO, 20, and DO.

• Some adjacent keywords must have one or more blank characters between them. Others do not require any; for example, BLOCK DATA can also be spelled BLOCKDATA. The following list shows which keywords have optional or required blanks:

<table>
<thead>
<tr>
<th>Optional Blanks</th>
<th>Required Blanks</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK DATA</td>
<td>CASE DEFAULT</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>DO WHILE</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>IMPLICIT type-specifier</td>
</tr>
<tr>
<td>ELSE IF</td>
<td>IMPLICIT NONE</td>
</tr>
<tr>
<td>ELSE WHERE</td>
<td>INTERFACE ASSIGNMENT</td>
</tr>
<tr>
<td>END BLOCK DATA</td>
<td>INTERFACE OPERATOR</td>
</tr>
<tr>
<td>END DO</td>
<td>MODULE PROCEDURE</td>
</tr>
<tr>
<td>END FILE</td>
<td>RECURSIVE FUNCTION</td>
</tr>
<tr>
<td>END FORALL</td>
<td>RECURSIVE SUBROUTINE</td>
</tr>
<tr>
<td>END FUNCTION</td>
<td>RECURSIVE type-specifier</td>
</tr>
<tr>
<td>END IF</td>
<td>type-specifier FUNCTION</td>
</tr>
<tr>
<td>END INTERFACE</td>
<td>type-specifier FUNCTION</td>
</tr>
<tr>
<td>END MODULE</td>
<td></td>
</tr>
<tr>
<td>END PROGRAM</td>
<td></td>
</tr>
<tr>
<td>END SELECT</td>
<td></td>
</tr>
<tr>
<td>END SUBROUTINE</td>
<td></td>
</tr>
</tbody>
</table>
For information on statement separators (;) in all forms, see Source Forms.

**Comment Indicator**

In free source form, the exclamation point character (!) indicates a comment if it is within a source line, or a comment line if it is the first character in a source line.

**Continuation Indicator**

In free source form, the ampersand character (&) indicates a continuation line (unless it appears in a Hollerith or character constant, or within a comment). The continuation line is the first noncomment line following the ampersand. Although Fortran 90 permits up to 39 continuation lines in free-form programs, Intel Fortran allows up to 511 continuation lines.

The following shows a continued statement:

```
TCOSH(Y) = EXP(Y) + & ! The initial statement line
EXP(-Y) ! A continuation line
```

If the first nonblank character on the next noncomment line is an ampersand, the statement continues at the character following the ampersand. For example, the preceding example can be written as follows:

```
TCOSH(Y) = EXP(Y) + 
& EXP(-Y)
```

If a lexical token must be continued, the first nonblank character on the next noncomment line must be an ampersand followed immediately by the rest of the token. For example:

```
TCOSH(Y) = EXP(Y) + EX&
&P(-Y)
```
If you continue a character constant, an ampersand must be the first non-blank character of the continued line; the statement continues with the next character following the ampersand. For example:

```fortran
ADVERTISER = "Davis, O'Brien, Chalmers & Peter & son"
ARCHITECT = "O'Connor, Emerson, and Davis & Associates"
```

If the ampersand is omitted on the continued line, the statement continues with the first non-blank character in the continued line. So, in the preceding example, the whitespace before "Associates" would be ignored.

The ampersand cannot be the only nonblank character in a line, or the only nonblank character before a comment; an ampersand in a comment is ignored.

**Fixed and Tab Source Forms**

In Fortran 95, fixed source form is identified as obsolescent.

In fixed and tab source forms, there are restrictions on where a statement can appear within a line.

By default, a statement can extend to character position 72. In this case, any text following position 72 is ignored and no warning message is printed. You can specify compiler option `extend-source` to extend source lines to character position 132.

Except in a character context, blanks are not significant and can be used freely throughout the program for maximum legibility.

Some Fortran compilers use blanks to pad short source lines out to 72 characters. By default, Intel Fortran does not. If portability is a concern, you can use the concatenation operator to prevent source lines from being padded by other Fortran compilers (see the example in "Continuation Indicator" below) or you can force short source lines to be padded by using compiler option `pad-source`.

**Comment Indicator**

In fixed and tab source forms, the exclamation point character (!) indicates a comment if it is within a source line. (It must not appear in column 6 of a fixed form line; that column is reserved for a continuation indicator.)

The letter C (or c), an asterisk (*), or an exclamation point (!) indicates a comment line when it appears in column 1 of a source line.
Continuation Indicator

In fixed and tab source forms, a continuation line is indicated by one of the following:

- For fixed form: Any character (except a zero or blank) in column 6 of a source line
- For tab form: Any digit (except zero) after the first tab

The compiler considers the characters following the continuation indicator to be part of the previous line. Although Fortran 95/90 permits up to 19 continuation lines in a fixed-form program, Intel Fortran allows up to 511 continuation lines.

If a zero or blank is used as a continuation indicator, the compiler considers the line to be an initial line of a Fortran statement.

The statement label field of a continuation line must be blank (except in the case of a debugging statement).

When long character or Hollerith constants are continued across lines, portability problems can occur. Use the concatenation operator to avoid such problems. For example:

```fortran
PRINT *, 'This is a very long character constant '//' + 'which is safely continued across lines'
```

Use this same method when initializing data with long character or Hollerith constants. For example:

```fortran
CHARACTER*(*) LONG_CONST
PARAMETER (LONG_CONST = 'This is a very long '//' + 'character constant which is safely continued '//' + 'across lines')
CHARACTER*100 LONG_VAL
DATA LONG_VAL /LONG_CONST/
```

Hollerith constants must be converted to character constants before using the concatenation method of line continuation.

The Fortran Standard requires that, within a program unit, the END statement cannot be continued, and no other statement in the program unit can have an initial line that appears to be the program unit END statement. In these instances, Intel Fortran produces warnings when standards checking is requested.
**Debugging Statement Indicator**

In fixed and tab source forms, the statement label field can contain a statement label, a comment indicator, or a debugging statement indicator.

The letter D indicates a debugging statement when it appears in column 1 of a source line. The initial line of the debugging statement can contain a statement label in the remaining columns of the statement label field.

If a debugging statement is continued onto more than one line, every continuation line must begin with a D and a continuation indicator.

By default, the compiler treats debugging statements as comments. However, you can specify compiler option d-lines to force the compiler to treat debugging statements as source text to be compiled.

**Fixed-Format Lines**

In fixed source form, a source line has columns divided into fields for statement labels, continuation indicators, statement text, and sequence numbers. Each column represents a single character.

The column positions for each field follow:

<table>
<thead>
<tr>
<th>Field</th>
<th>Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statement label</td>
<td>1 through 5</td>
</tr>
<tr>
<td>Continuation indicator</td>
<td>6</td>
</tr>
<tr>
<td>Statement</td>
<td>7 through 72 (or 132 with compiler option extend-source)</td>
</tr>
<tr>
<td>Sequence number</td>
<td>73 through 80</td>
</tr>
</tbody>
</table>

By default, a sequence number or other identifying information can appear in columns 73 through 80 of any fixed-format line in an Intel Fortran program. The compiler ignores the characters in this field.

If you extend the statement field to position 132, the sequence number field does not exist.

**NOTE.** If you use the sequence number field, do not use tabs anywhere in the source line, or the compiler may interpret the sequence numbers as part of the statement field in your program.
See Also
- Fixed and Tab Source Forms
- Source Forms
- Fixed and Tab Source Forms
- extend-source compiler option

Tab-Format Lines
In tab source form, you can specify a statement label field, a continuation indicator field, and a statement field, but not a sequence number field.

The following figure shows equivalent source lines coded with tab and fixed source form.

Line Formatting Example

The statement label field precedes the first tab character. The continuation indicator field and statement field follow the first tab character.
The continuation indicator is any nonzero digit. The statement field can contain any Fortran statement. A Fortran statement cannot start with a digit.

If a statement is continued, a continuation indicator must be the first character (following the first tab) on the continuation line.

Many text editors and terminals advance the terminal print carriage to a predefined print position when you press the <Tab> key. However, the Intel Fortran compiler does not interpret the tab character in this way. It treats the tab character in a statement field the same way it treats a blank character. In the source listing that the compiler produces, the tab causes the character that follows to be printed at the next tab stop (usually located at columns 9, 17, 25, 33, and so on).

**NOTE.** If you use the sequence number field, do not use tabs anywhere in the source line, or the compiler may interpret the sequence numbers as part of the statement field in your program.

### Source Code Useable for All Source Forms

To write source code that is useable for all source forms (free, fixed, or tab), follow these rules:

<table>
<thead>
<tr>
<th>Category</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blanks</td>
<td>Treat as significant (see Free Source Form).</td>
</tr>
<tr>
<td>Statement labels</td>
<td>Place in column positions 1 through 5 (or before the first tab character).</td>
</tr>
<tr>
<td>Statements</td>
<td>Start in column position 7 (or after the first tab character).</td>
</tr>
<tr>
<td>Comment indicator</td>
<td>Use only !. Place anywhere except in column position 6 (or immediately after the first tab character).</td>
</tr>
</tbody>
</table>
Continuation indicator

The following example is valid for all source forms:

Column:

12345678... 73

! Define the user function MY_SIN

DOUBLE PRECISION FUNCTION MY_SIN(X)

MY_SIN = X - X**3/FACTOR(3) + X**5/FACTOR(5) &

& - X**7/FACTOR(7)

CONTAINS

INTEGER FUNCTION FACTOR(N)

FACTOR = 1

DO 10 I = N, 1, -1

10 FACTOR = FACTOR * I

END FUNCTION FACTOR

END FUNCTION MY_SIN
Data Types, Constants, and Variables

Each constant, variable, array, expression, or function reference in a Fortran statement has a data type. The data type of these items can be inherent in their construction, implied by convention, or explicitly declared.

Each data type has the following properties:

- A name
  The names of the intrinsic data types are predefined, while the names of derived types are defined in derived-type definitions. Data objects (constants, variables, or parts of constants or variables) are declared using the name of the data type.
- A set of associated values
  Each data type has a set of valid values. Integer and real data types have a range of valid values. Complex and derived types have sets of values that are combinations of the values of their individual components.
- A way to represent constant values for the data type
  A constant is a data object with a fixed value that cannot be changed during program execution. The value of a constant can be a numeric value, a logical value, or a character string.
  A constant that does not have a name is a literal constant. A literal constant must be of intrinsic type and it cannot be array-valued.
  A constant that has a name is a named constant. A named constant can be of any type, including derived type, and it can be array-valued. A named constant has the PARAMETER attribute and is specified in a type declaration statement or PARAMETER statement.
- A set of operations to manipulate and interpret these values
  The data type of a variable determines the operations that can be used to manipulate it. Besides intrinsic operators and operations, you can also define operators and operations.

Intrinsic Data Types

Intel® Fortran provides the following intrinsic data types:

- INTEGER
  There are four kind parameters for data of type integer:
  - INTEGER([KIND=]1) or INTEGER*1
  - INTEGER([KIND=]2) or INTEGER*2
• INTEGER([KIND=]4) or INTEGER*4
• INTEGER([KIND=]8) or INTEGER*8

• REAL
There are three kind parameters for data of type real:
• REAL([KIND=]4) or REAL*4
• REAL([KIND=]8) or REAL*8
• REAL([KIND=]16) or REAL*16

• DOUBLE PRECISION
No kind parameter is permitted for data declared with type DOUBLE PRECISION. This data type is the same as REAL([KIND=]8).

• COMPLEX
There are two kind parameters for data of type complex:
• COMPLEX([KIND=]4) or COMPLEX*8
• COMPLEX([KIND=]8) or COMPLEX*16
• COMPLEX([KIND=]16) or COMPLEX*32

• DOUBLE COMPLEX
No kind parameter is permitted for data declared with type DOUBLE COMPLEX. This data type is the same as COMPLEX([KIND=]8).

• LOGICAL
There are four kind parameters for data of type logical:
• LOGICAL([KIND=]1) or LOGICAL*1
• LOGICAL([KIND=]2) or LOGICAL*2
• LOGICAL([KIND=]4) or LOGICAL*4
• LOGICAL([KIND=]8) or LOGICAL*8

• CHARACTER
There is one kind parameter for data of type character: CHARACTER([KIND=]1).

• BYTE
This is a 1-byte value; the data type is equivalent to INTEGER([KIND=]1).
The intrinsic function KIND can be used to determine the kind type parameter of a representation method.

For more portable programs, you should not use the forms INTEGER([KIND]=n) or REAL([KIND]=n). You should instead define a PARAMETER constant using the SELECTED_INT_KIND or SELECTED_REAL_KIND function, whichever is appropriate. For example, the following statements define a PARAMETER constant for an INTEGER kind that has 9 digits:

```fortran
INTEGER, PARAMETER :: MY_INT_KIND = SELECTED_INT_KIND(9)
...
INTEGER(MY_INT_KIND) :: J
...
```

Note that the syntax :: is used in type declaration statements.

The following sections describe the intrinsic data types and forms for literal constants for each type.

See Also
- Data Types, Constants, and Variables
- Integer Data Types
- Real Data Types
- KIND
- Declaration Statements for Noncharacter Types
- Declaration Statements for Character Types
- Expressions
- Data Type Storage Requirements table

Integer Data Types

Integer data types can be specified as follows:

```fortran
INTEGER
INTEGER([KIND]=n)
INTEGER* n
```

- `n` is an initialization expression that evaluates to kind 1, 2, 4, or 8.

If a kind parameter is specified, the integer has the kind specified. If a kind parameter is not specified, integer constants are interpreted as follows:

- If the integer constant is within the default integer kind range, the kind is `default integer`. 

...
If the integer constant is outside the default integer kind range, the kind of the integer constant is the smallest integer kind that holds the constant. Default integer is affected by compiler option integer-size, the INTEGER compiler directive, and the OPTIONS statement. The intrinsic inquiry function KIND returns the kind type parameter, if you do not know it. You can use the intrinsic function SELECTED_INT_KIND to find the kind values that provide a given range of integer values. The decimal exponent range is returned by the intrinsic function RANGE.

Examples

The following examples show ways an integer variable can be declared.

An entity-oriented example is:

```fortran
INTEGER, DIMENSION(:), POINTER :: days, hours
INTEGER(2), POINTER :: k, limit
INTEGER(1), DIMENSION(10) :: min
```

An attribute-oriented example is:

```fortran
INTEGER days, hours
INTEGER(2) k, limit
INTEGER(1) min
DIMENSION days(:), hours(:), min (10)
POINTER days, hours, k, limit
```

An integer can be used in certain cases when a logical value is expected, such as in a logical expression evaluating a condition, as in the following:

```fortran
INTEGER I, X
READ (*,*) I
IF (I) THEN
   X = 1
END IF
```

Integer Constants

An integer constant is a whole number with no decimal point. It can have a leading sign and is interpreted as a decimal number.

Integer constants take the following form:
Is a sign; required if negative (-), optional if positive (+).

Is a decimal digit (0 through 9). Any leading zeros are ignored.

Is the optional kind parameter: 1 for INTEGER(1), 2 for INTEGER(2), 4 for INTEGER(4), or 8 for INTEGER(8). It must be preceded by an underscore (_).

An unsigned constant is assumed to be nonnegative.

Integer constants are interpreted as decimal values (base 10) by default. To specify a constant that is not in base 10, use the following extension syntax:

Is an optional plus (+) or minus (-) sign.

Is any constant from 2 through 36.

If base is omitted but # is specified, the integer is interpreted in base 16. If both base and # are omitted, the integer is interpreted in base 10.

For bases 11 through 36, the letters A through Z represent numbers greater than 9. For example, for base 36, A represents 10, B represents 11, C represents 12, and so on, through Z, which represents 35. The case of the letters is not significant.

Note that compiler option integer-size can affect INTEGER data.

**Examples**

**Table 527: Valid Integer (base 10) Constants**

<table>
<thead>
<tr>
<th>Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>-127</td>
</tr>
<tr>
<td>+32123</td>
</tr>
<tr>
<td>47_2</td>
</tr>
</tbody>
</table>

**Table 528: Invalid Integer (base 10) Constants**

<table>
<thead>
<tr>
<th>Constant</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>9999999999999999999</td>
<td>Number too large</td>
</tr>
<tr>
<td>3.14</td>
<td>Decimal point not allowed; this is a valid REAL constant</td>
</tr>
</tbody>
</table>
Comma not allowed.

3 3 is not a valid kind type for integers.

The following seven integers are all assigned a value equal to 3,994,575 decimal:

\[ I = 2#1111001111001111001111 \]

\[ m = 7#45644664 \]

\[ J = +8#17171717 \]

\[ K = #3CF3CF \]

\[ n = +17#2DE110 \]

\[ L = 3994575 \]

\[ \text{index} = 36#2DM8F \]

You can use integer constants to assign values to data. The following table shows assignments to different data and lists the integer and hexadecimal values in the data:

<table>
<thead>
<tr>
<th>Fortran Assignment</th>
<th>Integer Value in Data</th>
<th>Hexadecimal Value in Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL(1)X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INTEGER(1)X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>X = -128</td>
<td>-128</td>
<td>Z'80'</td>
</tr>
<tr>
<td>X = 127</td>
<td>127</td>
<td>Z'7F'</td>
</tr>
<tr>
<td>X = 255</td>
<td>-1</td>
<td>Z'FF'</td>
</tr>
<tr>
<td>LOGICAL(2)X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INTEGER(2)X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>X = 255</td>

Building Applications for details on the ranges for integer types and kinds

**Real Data Types**

Real data types can be specified as follows:

- REAL
- REAL([KIND=] n)
- REAL* n
- DOUBLE PRECISION

where

- REAL is an initialization expression that evaluates to kind 4, 8, or 16.
- If a kind parameter is specified, the real constant has the kind specified. If a kind parameter is not specified, the kind is default real.
- Default real is affected by compiler options specifying real size and by the REAL directive.
- The default KIND for DOUBLE PRECISION is affected by compiler option double-size. If this compiler option is not specified, default DOUBLE PRECISION is REAL(8).
- No kind parameter is permitted for data declared with type DOUBLE PRECISION.
- The intrinsic inquiry function KIND returns the kind type parameter. The intrinsic inquiry function RANGE returns the decimal exponent range, and the intrinsic function PRECISION returns the decimal precision. You can use the intrinsic function SELECTED_REAL_KIND to find the kind values that provide a given precision and exponent range.

**Examples**

The following examples show how real variables can be declared.

An entity-oriented example is:

```
REAL (KIND = high), OPTIONAL :: testval
REAL, SAVE :: a(10), b(20,30)
```

An attribute-oriented example is:

```
REAL (KIND = high) testval
REAL a(10), b(20,30)
OPTIONAL testval
SAVE a, b
```
General Rules for Real Constants

A real constant approximates the value of a mathematical real number. The value of the constant can be positive, zero, or negative.

The following is the general form of a real constant with no exponent part:

\[ s[n...][_k] \]

A real constant with an exponent part has one of the following forms:

\[ s[n...]E[s]nn...[_k] \]
\[ s[n...]D[s]nn... \]
\[ s[n...]Q[s]nn... \]

- \( s \) is a sign; required if negative (-), optional if positive (+).
- \( n \) is a decimal digit (0 through 9). A decimal point must appear if the real constant has no exponent part.
- \( k \) is the optional kind parameter: 4 for REAL(4), 8 for REAL(8), or 16 for REAL(16). It must be preceded by an underscore ( _ ).

Description

Leading zeros (zeros to the left of the first nonzero digit) are ignored in counting significant digits. For example, in the constant 0.0001234567, all of the nonzero digits, and none of the zeros, are significant. (See the following sections for the number of significant digits each kind type parameter typically has).

The exponent represents a power of 10 by which the preceding real or integer constant is to be multiplied (for example, 1.0E6 represents the value 1.0 * 10**6).

A real constant with no exponent part and no kind type parameter is (by default) a single-precision (REAL(4)) constant. You can change the default behavior by specifying compiler option fpconstant.

If the real constant has no exponent part, a decimal point must appear in the string (anywhere before the optional kind parameter). If there is an exponent part, a decimal point is optional in the string preceding the exponent part; the exponent part must not contain a decimal point.

The exponent letter E denotes a single-precision real (REAL(4)) constant, unless the optional kind parameter specifies otherwise. For example, -9.E2_8 is a double-precision constant (which can also be written as -9.D2).

The exponent letter D denotes a double-precision real (REAL(8)) constant.

The exponent letter Q denotes a quad-precision real (REAL(16)) constant.
A minus sign must appear before a negative real constant; a plus sign is optional before a positive constant. Similarly, a minus sign must appear between the exponent letter (E, D, or Q) and a negative exponent, whereas a plus sign is optional between the exponent letter and a positive exponent.

If the real constant includes an exponent letter, the exponent field cannot be omitted, but it can be zero.

To specify a real constant using both an exponent letter and a kind parameter, the exponent letter must be E, and the kind parameter must follow the exponent part.

**See Also**
- Real Data Types
- fpconstant compiler option

**REAL(4) Constants**
A single-precision REAL constant occupies four bytes of memory. The number of digits is unlimited, but typically only the leftmost seven digits are significant.

IEEE* S_floating format is used.

Note that compiler option real-size can affect REAL data.

**Examples**

**Table 529: Valid REAL(4) Constants**

<table>
<thead>
<tr>
<th>Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.14159</td>
</tr>
<tr>
<td>3.14159_4</td>

*Building Applications* for details on the format and range of REAL(4) data

**REAL(8) or DOUBLE PRECISION Constants**

A REAL(8) or DOUBLE PRECISION constant has more than twice the accuracy of a REAL(4) number, and greater range.

A REAL(8) or DOUBLE PRECISION constant occupies eight bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 15 digits are significant.

IEEE T_floating format is used.

Note that compiler option double-size can affect DOUBLE PRECISION data.

The default KIND for DOUBLE PRECISION is affected by compiler option double-size.

**Examples**

**Table 531: Valid REAL(8) or DOUBLE PRECISION Constants**

123456789D+5

**Building Applications** for details on the format and range of DOUBLE PRECISION (REAL(8)) data

### REAL(16) Constants

A REAL(16) constant has more than four times the accuracy of a REAL(4) number, and a greater range.

A REAL(16) constant occupies 16 bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 33 digits are significant.

IEEE X_floating format is used.

### Examples

#### Table 533: Valid REAL(16) Constants

### Complex Data Types

Complex data types can be specified as follows:

- `COMPLEX`
- `COMPLEX([KIND=]n)`
- `COMPLEX*8`
- `DOUBLE COMPLEX`

$n$ is an initialization expression that evaluates to kind 4, 8, or 16.
$s$ is 8, 16, or 32. `COMPLEX(4)` is specified as `COMPLEX*8`; `COMPLEX(8)` is specified as `COMPLEX*16`; `COMPLEX(16)` is specified as `COMPLEX*32`.

If a kind parameter is specified, the complex constant has the kind specified. If no kind parameter is specified, the kind of both parts is default real, and the constant is of type default complex.

Default real is affected by compiler option real-size and by the REAL directive.

The default KIND for DOUBLE COMPLEX is affected by compiler option double-size. If the compiler option is not specified, default DOUBLE COMPLEX is `COMPLEX(8)`.

No kind parameter is permitted for data declared with type DOUBLE COMPLEX.

### Examples

The following examples show how complex variables can be declared.

An entity-oriented example is:

```fortran
COMPLEX (4), DIMENSION (8) :: cz, cq
```
An attribute-oriented example is:

COMPLEX(4) cz, cq
DIMENSION(8) cz, cq

**General Rules for Complex Constants**

A *complex constant* approximates the value of a mathematical complex number. The constant is a pair of real or integer values, separated by a comma, and enclosed in parentheses. The first constant represents the real part of that number; the second constant represents the imaginary part.

The following is the general form of a complex constant:

\[(c, c)\]

Is as follows:

- For COMPLEX(4) constants, \(c\) is an integer or REAL(4) constant.
- For COMPLEX(8) constants, \(c\) is an integer, REAL(4) constant, or DOUBLE PRECISION (REAL(8)) constant. At least one of the pair must be DOUBLE PRECISION.
- For COMPLEX(16) constants, \(c\) is an integer, REAL(4) constant, REAL(8) constant, or REAL(16) constant. At least one of the pair must be a REAL(16) constant.

Note that the comma and parentheses are required.

**COMPLEX(4) Constants**

A COMPLEX(4) constant is a pair of integer or single-precision real constants that represent a complex number.

A COMPLEX(4) constant occupies eight bytes of memory and is interpreted as a complex number. If the real and imaginary part of a complex literal constant are both real, the kind parameter value is that of the part with the greater decimal precision.

The rules for REAL(4) constants apply to REAL(4) constants used in COMPLEX constants. (See **General Rules for Complex Constants** and **REAL(4) Constants** for the rules on forming REAL(4) constants.)

The REAL(4) constants in a COMPLEX constant have IEEE S_floating format.

*Note that compiler option real-size can affect REAL data.*
Examples
Table 535: Valid COMPLEX(4) Constants

(1.7039, -1.70391)
(44.36_4, -12.2E16_4)
(+12739E3, 0.)
(1, 2)

Table 536: Invalid COMPLEX(4) Constants

(1.23, ) Missing second integer or single-precision real constant.
(1.0, 2H12) Hollerith constant not allowed.

See Also
- Complex Data Types
- General Rules for Complex Constants
- real-size compiler option

Building Applications for details on the format and range of COMPLEX (COMPLEX(4)) data

COMPLEX(8) or DOUBLE COMPLEX Constants

A COMPLEX(8) or DOUBLE COMPLEX constant is a pair of constants that represents a complex number. One of the pair must be a double-precision real constant, the other can be an integer, single-precision real, or double-precision real constant.

A COMPLEX(8) or DOUBLE COMPLEX constant occupies 16 bytes of memory and is interpreted as a complex number.

The rules for DOUBLE PRECISION (REAL(8)) constants also apply to the double precision portion of COMPLEX(8) or DOUBLE COMPLEX constants. (See General Rules for Complex Constants and REAL(8) or DOUBLE PRECISION Constants for the rules on forming DOUBLE PRECISION constants.)

The DOUBLE PRECISION constants in a COMPLEX(8) or DOUBLE COMPLEX constant have IEEE T_floating format.

The default KIND for DOUBLE COMPLEX is affected by compiler option double-size.
Examples

Table 537: Valid COMPLEX(8) or DOUBLE COMPLEX Constants

- (1.7039, -1.7039D0)
- (547.3E0_8, -1.44_8)
- (1.7039E0, -1.7039D0)
- (+12739D3, 0.D0)

Table 538: Invalid COMPLEX(8) or DOUBLE COMPLEX Constants

- (1.23D0,)
  - Second constant missing.
- (1D1,2H12)
  - Hollerith constants not allowed.
- (1,1.2)
  - Neither constant is DOUBLE PRECISION; this is a valid single-precision constant.

See Also

- Complex Data Types
- General Rules for Complex Constants
- -double-size

Building Applications for details on the format and range of DOUBLE COMPLEX data

COMPLEX(16) Constants

A COMPLEX(16) constant is a pair of constants that represents a complex number. One of the pair must be a REAL(16) constant, the other can be an integer, single-precision real, double-precision real, or REAL(16) constant.

A COMPLEX(16) constant occupies 32 bytes of memory and is interpreted as a complex number. The rules for REAL(16) constants apply to REAL(16) constants used in COMPLEX constants. (See General Rules for Complex Constants and REAL(16) Constants for the rules on forming REAL(16) constants.)

The REAL(16) constants in a COMPLEX constant have IEEE X_floating format.

Note that compiler option real-size can affect REAL data.
Examples

Table 539: Valid COMPLEX(16) Constants

(1.7039,-1.7039Q2)
(547.3E0_16,-1.44)
(+12739D3,0.Q0)

Table 540: Invalid COMPLEX(16) Constants

(1.23Q0,)
(1D1,2H12)
(1.7039E0,-1.7039D0)

See Also
- Complex Data Types

- real-size compiler option

Building Applications for details on the format and range of COMPLEX(16) data

Logical Data Types

Logical data types can be specified as follows:

LOGICAL
LOGICAL([KIND=]n)

LOGICAL*n

n Is an initialization expression that evaluates to kind 1, 2, 4, or 8.

If a kind parameter is specified, the logical constant has the kind specified. If no kind parameter is specified, the kind of the constant is default logical.

Examples

The following examples show how logical variables can be declared.
An entity-oriented example is:

```fortran
LOGICAL, ALLOCATABLE :: flag1, flag2
LOGICAL (KIND = byte), SAVE :: doit, dont
```

An attribute-oriented example is:

```fortran
LOGICAL flag1, flag2
LOGICAL (KIND = byte) doit, dont
ALLOCATABLE flag1, flag2
SAVE doit, dont
```

**Logical Constants**

A logical constant represents only the logical values true or false, and takes one of the following forms:

- `.TRUE.[_k]`
- `.FALSE.[_k]`

`k` is the optional kind parameter: 1 for LOGICAL(1), 2 for LOGICAL(2), 4 for LOGICAL(4), or 8 for LOGICAL(8). It must be preceded by an underscore ( `_ `).

The numeric value of `.TRUE.` and `.FALSE. can be -1 and 0 or 1 and 0 depending on compiler option fpscomp [no]logicals. Logical data can take on integer data values. Logical data type ranges correspond to their comparable integer data type ranges. For example, the LOGICAL(2) range is the same as the INTEGER(2) range.

**See Also**

- Logical Data Types

*Building Applications* for details on integer data type ranges

**Character Data Type**

The character data type can be specified as follows:

```fortran
CHARACTER
CHARACTER([LEN=] len)
CHARACTER(LEN= len, KIND= n)
CHARACTER(len, [KIND=] n)
```
CHARACTER(KIND= \( n \), LEN= \( len \))

CHARACTER* \( len \)

\( n \) is an initialization expression that evaluates to kind 1.

\( len \) is a string length (not a kind). For more information, see Declaration Statements for Character Types.

If no kind type parameter is specified, the kind of the constant is default character.

On Windows systems, several Multi-Byte Character Set (MBCS) functions are available to manipulate special non-English characters.

**Character Constants**

A character constant is a character string enclosed in delimiters (apostrophes or quotation marks). It takes one of the following forms:

\[
[k_\_][ch...][c]
\]

\[
[k_\_]["ch..."][c]
\]

\( k \) is the optional kind parameter: 1 (the default). It must be followed by an underscore (\( _ \)). Note that in character constants, the kind must precede the constant.

\( ch \) is an ASCII character.

\( C \) is a C string specifier. C strings can be used to define strings with nonprintable characters. For more information, see C Strings in Character Constants.

**Description**

The value of a character constant is the string of characters between the delimiters. The value does not include the delimiters, but does include all blanks or tabs within the delimiters.

If a character constant is delimited by apostrophes, use two consecutive apostrophes ("'" ) to place an apostrophe character in the character constant.

Similarly, if a character constant is delimited by quotation marks, use two consecutive quotation marks ("" ) to place a quotation mark character in the character constant.

The length of the character constant is the number of characters between the delimiters, but two consecutive delimiters are counted as one character.

The length of a character constant must be in the range of 0 to 7188. Each character occupies one byte of memory.
If a character constant appears in a numeric context (such as an expression on the right side of an arithmetic assignment statement), it is considered a Hollerith constant.

A zero-length character constant is represented by two consecutive apostrophes or quotation marks.

**Examples**

**Table 541: Valid Character Constants**

<table>
<thead>
<tr>
<th>Character Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;WHAT KIND TYPE? &quot;</td>
</tr>
<tr>
<td>'TODAY''S DATE IS: '</td>
</tr>
<tr>
<td>&quot;The average is: &quot;</td>
</tr>
<tr>
<td>''</td>
</tr>
</tbody>
</table>

**Table 542: Invalid Character Constants**

<table>
<thead>
<tr>
<th>Character Constant</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>'HEADINGS</td>
<td>No trailing apostrophe.</td>
</tr>
<tr>
<td>'Map Number:&quot;</td>
<td>Beginning delimiter does not match ending delimiter.</td>
</tr>
</tbody>
</table>

**See Also**

- Character Data Type
- Declaration Statements for Character Types

**C Strings in Character Constants**

String values in the C language are terminated with null characters (CHAR(0)) and can contain nonprintable characters (such as backspace).

Nonprintable characters are specified by escape sequences. An escape sequence is denoted by using the backslash (\) as an escape character, followed by a single character indicating the nonprintable character desired.

This type of string is specified by using a standard string constant followed by the character C. The standard string constant is then interpreted as a C-language constant. Backslashes are treated as escapes, and a null character is automatically appended to the end of the string (even if the string already ends in a null character).

The following table shows the escape sequences that are allowed in character constants:
### Table 543: C-Style Escape Sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Represents</th>
</tr>
</thead>
<tbody>
<tr>
<td>\a or \A</td>
<td>A bell</td>
</tr>
<tr>
<td>\b or \B</td>
<td>A backspace</td>
</tr>
<tr>
<td>\f or \F</td>
<td>A formfeed</td>
</tr>
<tr>
<td>\n or \N</td>
<td>A new line</td>
</tr>
<tr>
<td>\r or \R</td>
<td>A carriage return</td>
</tr>
<tr>
<td>\t or \T</td>
<td>A horizontal tab</td>
</tr>
<tr>
<td>\v or \V</td>
<td>A vertical tab</td>
</tr>
<tr>
<td>\xhh or \Xhh</td>
<td>A hexadecimal bit pattern</td>
</tr>
<tr>
<td>\ooo</td>
<td>An octal bit pattern</td>
</tr>
<tr>
<td>\0</td>
<td>A null character</td>
</tr>
<tr>
<td>\</td>
<td>A backslash</td>
</tr>
</tbody>
</table>

If a string contains an escape sequence that isn’t in this table, the backslash is ignored.

A C string must also be a valid Fortran string. If the string is delimited by apostrophes, apostrophes in the string itself must be represented by two consecutive apostrophes (‘ ’).

For example, the escape sequence `\'string` causes a compiler error because Fortran interprets the apostrophe as the end of the string. The correct form is `\''string`.

If the string is delimited by quotation marks, quotation marks in the string itself must be represented by two consecutive quotation marks (" ").

The sequences \ooo and \xhh allow any ASCII character to be given as a one- to three-digit octal or a one- to two-digit hexadecimal character code. Each octal digit must be in the range 0 to 7, and each hexadecimal digit must be in the range 0 to F. For example, the C strings `\010'C` and `\x08'C` both represent a backspace character followed by a null character.

The C string `\"abcd\'C` is equivalent to the string `\"abcd` with a null character appended. The string `\"C` represents the ASCII null character.
Character Substrings

A character substring is a contiguous segment of a character string. It takes one of the following forms:

\[ v ([e_1]:[e_2]) \]
\[ a (s [, s] . . . ) ([e_1]:[e_2]) \]

- **v** is a character scalar constant, or the name of a character scalar variable or character structure component.
- **e_1** is a scalar integer (or other numeric) expression specifying the leftmost character position of the substring; the starting point.
- **e_2** is a scalar integer (or other numeric) expression specifying the rightmost character position of the substring; the ending point.
- **a** is a subscript expression.
- **s** is the name of a character array.

Both **e_1** and **e_2** must be within the range 1, 2, ..., \( len \), where \( len \) is the length of the parent character string. If **e_1** exceeds **e_2**, the substring has length zero.

Description

Character positions within the parent character string are numbered from left to right, beginning at 1.

If the value of the numeric expression **e_1** or **e_2** is not of type integer, it is converted to integer before use (any fractional parts are truncated).

If **e_1** is omitted, the default is 1. If **e_2** is omitted, the default is \( len \). For example, \( \text{NAMES(1,3)(:7)} \) specifies the substring starting with the first character position and ending with the seventh character position of the character array element \( \text{NAMES(1,3)} \).

Examples

Consider the following example:

```plaintext
CHARACTER*8 C, LABEL
LABEL = 'XVERSUSY'
C = LABEL(2:7)
```

\( \text{LABEL(2:7)} \) specifies the substring starting with the second character position and ending with the seventh character position of the character variable assigned to \( \text{LABEL} \), so \( \text{C} \) has the value 'VERSUS'.

1783
Consider the following example:

```fortran
TYPE ORGANIZATION
  INTEGER ID
  CHARACTER*35 NAME
END TYPE ORGANIZATION

TYPE(ORGANIZATION) DIRECTOR
  CHARACTER*25 BRANCH, STATE(50)
```

The following are valid substrings based on this example:

- `BRANCH(3:15)` ! parent string is a scalar variable
- `STATE(20) (1:3)` ! parent string is an array element
- `DIRECTOR%NAME(:)` ! parent string is a structure component

Consider the following example:

```fortran
CHARACTER(*), PARAMETER :: MY_BRANCH = "CHAPTER 204"
CHARACTER(3) BRANCH_CHAP
BRANCH_CHAP = MY_BRANCH(9:11) ! parent string is a character constant
```

`BRANCH_CHAP` is a character string of length 3 that has the value '204'.

Derived Data Types

You can create derived data types from intrinsic data types or previously defined derived types.

A derived type is resolved into "ultimate" components that are either of intrinsic type or are pointers.

The set of values for a specific derived type consists of all possible sequences of component values permitted by the definition of that derived type. Structure constructors are used to specify values of derived types.
Nonintrinsic assignment for derived-type entities must be defined by a subroutine with an ASSIGNMENT interface. Any operation on derived-type entities must be defined by a function with an OPERATOR interface. Arguments and function values can be of any intrinsic or derived type.

Derived-Type Definition
A derived-type definition specifies the name of a user-defined type and the types of its components.

See Also
- Derived Data Types
- TYPE

Default Initialization
Default initialization occurs if initialization appears in a derived-type component definition. (This is a Fortran 95 feature.)
The specified initialization of the component will apply even if the definition is PRIVATE.
Default initialization applies to dummy arguments with INTENT(OUT). It does not imply the derived-type component has the SAVE attribute.
Explicit initialization in a type declaration statement overrides default initialization.
To specify default initialization of an array component, use a constant expression that includes one of the following:

- An array constructor
- A single scalar that becomes the value of each array element

Pointers can have an association status of associated, disassociated, or undefined. If no default initialization status is specified, the status of the pointer is undefined. To specify disassociated status for a pointer component, use =>NULL().

**Examples**

You do not have to specify initialization for each component of a derived type. For example:

```fortran
TYPE REPORT
    CHARACTER (LEN=20) REPORT_NAME
    INTEGER DAY
    CHARACTER (LEN=3) MONTH
    INTEGER :: YEAR = 1995 ! Only component with default initialization
END TYPE REPORT
```

Consider the following:

```fortran
TYPE (REPORT), PARAMETER :: NOV_REPORT = REPORT ("Sales", 15, "NOV", 1996)
```

In this case, the explicit initialization in the type declaration statement overrides the YEAR component of NOV_REPORT.

The default initial value of a component can also be overridden by default initialization specified in the type definition. For example:

```fortran
TYPE MGR_REPORT
    TYPE (REPORT) :: STATUS = NOV_REPORT
    INTEGER NUM
END TYPE MGR_REPORT
```

In this case, the STATUS component of STARTUP gets its initial value from NOV_REPORT, overriding the initialization for the YEAR component.

**Structure Components**

A reference to a component of a derived-type structure takes the following form:
parent [%component [(s-list)]] ... %component [(s-list)]

parent Is the name of a scalar or array of derived type. The percent sign (%) is called a component selector.

component Is the name of a component of the immediately preceding parent or component.

s-list Is a list of one or more subscripts. If the list contains subscript triplets or vector subscripts, the reference is to an array section. Each subscript must be a scalar integer (or other numeric) expression with a value that is within the bounds of its dimension. The number of subscripts in any s-list must equal the rank of the immediately preceding parent or component.

Description

Each parent or component (except the rightmost) must be of derived type.

The parent or one of the components can have nonzero rank (be an array). Any component to the right of a parent or component of nonzero rank must not have the POINTER attribute.

The rank of the structure component is the rank of the part (parent or component) with nonzero rank (if any); otherwise, the rank is zero. The type and type parameters (if any) of a structure component are those of the rightmost part name.

The structure component must not be referenced or defined before the declaration of the parent object.

If the parent object has the INTENT, TARGET, or PARAMETER attribute, the structure component also has the attribute.

Examples

The following example shows a derived-type definition with two components:

```
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
```

The following shows how to declare CONTRACT to be of type EMPLOYEE:

```
TYPE(EMPLOYEE) :: CONTRACT
```
Note that both examples started with the keyword TYPE. The first (initial) statement of a derived-type definition is called a derived-type statement, while the statement that declares a derived-type object is called a TYPE statement.

The following example shows how to reference component ID of parent structure CONTRACT:

```
CONTRACT%ID
```

The following example shows a derived type with a component that is a previously defined type:

```
TYPE DOT
  REAL X, Y
END TYPE DOT

....

TYPE SCREEN
  TYPE(DOT) C, D
END TYPE SCREEN
```

The following declares a variable of type SCREEN:

```
TYPE(SCREEN) M
```

Variable M has components M%C and M%D (both of type DOT); M%C has components M%C%X and M%C%Y of type REAL.

The following example shows a derived type with a component that is an array:

```
TYPE CAR_INFO
  INTEGER YEAR
  CHARACTER(LEN=15), DIMENSION(10) :: MAKER
  CHARACTER(LEN=10) MODEL, BODY_TYPE*8
  REAL PRICE
END TYPE

....

TYPE(CAR_INFO) MY_CAR
```

Note that MODEL has a character length of 10, but BODY_TYPE has a character length of 8. You can assign a value to a component of a structure; for example:

```
MY_CAR%YEAR = 1985
```
The following shows an array structure component:

MY_CARR\[\[\text{AKER}\]

In the preceding example, if a subscript list (or substring) was appended to MAKER, the reference would not be to an array structure component, but to an array element or section.

Consider the following:

MY_CARR\[\[\text{AKER}(2) (4:10)

In this case, the component is substring 4 to 10 of the second element of array MAKER.

Consider the following:

TYPE CHARGE

INTEGER PARTS(40)
REAL LABOR
REAL MILEAGE
END TYPE CHARGE

TYPE(CHARGE) MONTH

TYPE(CHARGE) YEAR(12)

Some valid array references for this type follow:

MONTH\%PARTS(I) ! An array element
MONTH\%PARTS(I:K) ! An array section
YEAR(I)%PARTS ! An array structure component (a whole array)
YEAR(J)%PARTS(I) ! An array element
YEAR(J)%PARTS(I:K) ! An array section
YEAR(J:K)%PARTS(I) ! An array section
YEAR%PARTS(I) ! An array section
The following example shows a derived type with a pointer component that is of the type being defined:

```fortran
TYPE NUMBER
   INTEGER NUM
   TYPE(NUMBER), POINTER :: START_NUM => NULL( )
   TYPE(NUMBER), POINTER :: NEXT_NUM => NULL( )
END TYPE
```

A type such as this can be used to construct linked lists of objects of type NUMBER. Note that the pointers are given the default initialization status of disassociated.

The following example shows a private type:

```fortran
TYPE, PRIVATE :: SYMBOL
   LOGICAL TEST
   CHARACTER(LEN=50) EXPLANATION
END TYPE SYMBOL
```

This type is private to the module. The module can be used by another scoping unit, but type SYMBOL is not available.

- Array Elements
- Array Sections
- Modules and Module Procedures

**Structure Constructors**

A structure constructor lets you specify scalar values of a derived type. It takes the following form:

```
d-name(expr-list)
```

* `d-name` is the name of the derived type.
* `expr-list` is a list of expressions specifying component values. The values must agree in number and order with the components of the derived type. If necessary, values are converted (according to the rules of assignment), to agree with their corresponding components in type and kind parameters.
Description

A structure constructor must not appear before its derived type is defined.

If a component of the derived type is an array, the shape in the expression list must conform to the shape of the component array.

If a component of the derived type is a pointer, the value in the expression list must evaluate to an object that would be a valid target in a pointer assignment statement. (A constant is not a valid target in a pointer assignment statement.)

If all the values in a structure constructor are constant expressions, the constructor is a derived-type constant expression.

Examples

Consider the following derived-type definition:

```
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
```

This can be used to produce the following structure constructor:

```
EMPLOYEE(3472, "John Doe")
```

The following example shows a type with a component of derived type:

```
TYPE ITEM
  REAL COST
  CHARACTER(LEN=30) SUPPLIER
  CHARACTER(LEN=20) ITEM_NAME
END TYPE ITEM

TYPE PRODUCE
  REAL MARKUP
  TYPE(ITEM) FRUIT
END TYPE PRODUCE
```

In this case, you must use an embedded structure constructor to specify the values of that component; for example:

```
PRODUCE(.70, ITEM (.25, "Daniels", "apple"))
```

Binary, Octal, Hexadecimal, and Hollerith Constants

Binary, octal, hexadecimal, and Hollerith constants are nondecimal constants. They have no intrinsic data type, but assume a numeric data type depending on their use.

Fortran 95/90 allows unsigned binary, octal, and hexadecimal constants to be used in DATA statements; the constant must correspond to an integer scalar variable.

In Intel Fortran, binary, octal, hexadecimal, and Hollerith constants can appear wherever numeric constants are allowed.

Binary Constants

A **binary constant** is an alternative way to represent a numeric constant. A binary constant takes one of the following forms:

- B'0[d...]'  
- B"0[d...]"

$d$ is a binary (base 2) digit (0 or 1).

You can specify up to 128 binary digits in a binary constant.

Examples

**Table 544: Valid Binary Constants**

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>B'0101110'</td>
</tr>
<tr>
<td>B&quot;1&quot;</td>
</tr>
</tbody>
</table>

**Table 545: Invalid Binary Constants**

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B'0112'</td>
<td>The character 2 is invalid.</td>
</tr>
<tr>
<td>B10011'</td>
<td>No apostrophe after the B.</td>
</tr>
<tr>
<td>&quot;1000001&quot;</td>
<td>No B before the first quotation mark.</td>
</tr>
</tbody>
</table>
See Also
- Binary, Octal, Hexadecimal, and Hollerith Constants
- Alternative Syntax for Binary, Octal, and Hexadecimal Constants

Octal Constants
An octal constant is an alternative way to represent numeric constants. An octal constant takes one of the following forms:

- $O'\{d...\}'$
- $O"\{d...\}"

$d$ is an octal (base 8) digit (0 through 7).

You can specify up to 128 bits (43 octal digits) in octal constants.

Examples

**Table 546: Valid Octal Constants**

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$O'07737'$</td>
</tr>
<tr>
<td>$O&quot;1&quot;$</td>
</tr>
</tbody>
</table>

**Table 547: Invalid Octal Constants**

<table>
<thead>
<tr>
<th>Example</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>$O'7782'$</td>
<td>The character 8 is invalid.</td>
</tr>
<tr>
<td>$07772'$</td>
<td>No apostrophe after the O.</td>
</tr>
<tr>
<td>&quot;0737&quot;</td>
<td>No O before the first quotation mark.</td>
</tr>
</tbody>
</table>

See Also
- Binary, Octal, Hexadecimal, and Hollerith Constants
- Alternative Syntax for Binary, Octal, and Hexadecimal Constants

Hexadecimal Constants
A hexadecimal constant is an alternative way to represent numeric constants. A hexadecimal constant takes one of the following forms:

- $Z'\{d...\}'$
- $Z"\{d...\}"

1793
\( d \) is a hexadecimal (base 16) digit (0 through 9, or an uppercase or lowercase letter in the range of A to F).

You can specify up to 128 bits (32 hexadecimal digits) in hexadecimal constants.

**Examples**

**Table 548: Valid Hexadecimal Constants**

- Z'AF9730'
- Z"FFABC"
- Z'84'

**Table 549: Invalid Hexadecimal Constants**

- Z'999.' Decimal not allowed.
- ZF9" No quotation mark after the Z.

**See Also**

- Binary, Octal, Hexadecimal, and Hollerith Constants
- Alternative Syntax for Binary, Octal, and Hexadecimal Constants

**Hollerith Constants**

A **Hollerith constant** is a string of printable ASCII characters preceded by the letter H. Before the H, there must be an unsigned, nonzero default integer constant stating the number of characters in the string (including blanks and tabs).

Hollerith constants are strings of 1 to 2000 characters. They are stored as byte strings, one character per byte.

**Examples**

**Table 550: Valid Hollerith Constants**

- 16HTODAY'S DATE IS:
- 1HB
- 4H ABC
Table 551: Invalid Hollerith Constants

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>3HABCD</td>
<td>Wrong number of characters.</td>
</tr>
<tr>
<td>0H</td>
<td>Hollerith constants must contain at least one character.</td>
</tr>
</tbody>
</table>

Determining the Data Type of Nondecimal Constants

Binary, octal, hexadecimal, and Hollerith constants have no intrinsic data type. In most cases, the default integer data type is assumed.

However, these constants can assume a numeric data type depending on their use. When the constant is used with a binary operator (including the assignment operator), the data type of the constant is the data type of the other operand. For example:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Data Type of Constant</th>
<th>Length of Constant (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(2) ICOUNT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INTEGER(4) JCOUNT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>INTEGER(4) N</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REAL(8) DOUBLE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REAL(4) RAFFIA, RALPHA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>RAFFIA = B'10011001111101011'</td>
<td>REAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>RAFFIA = Z'99AF2'</td>
<td>REAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>RALPHA = 4HABCD</td>
<td>REAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>DOUBLE = B'11111111110011010'</td>
<td>REAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE = Z'FFF99A'</td>
<td>REAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE = 8HABCDEFGH</td>
<td>REAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>Statement</td>
<td>Data Type of Constant</td>
<td>Length of Constant (in bytes)</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>JCOUNT = ICOUNT + B'011101110111'</td>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>JCOUNT = ICOUNT + O'777'</td>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>JCOUNT = ICOUNT + 2HXY</td>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>IF (N .EQ. B'1010100') GO TO 10</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>IF (N .EQ. O'123') GO TO 10</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>IF (N. EQ. 1HZ) GO TO 10</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
</tbody>
</table>

When a specific data type (generally integer) is required, that type is assumed for the constant. For example:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Data Type of Constant</th>
<th>Length of Constant (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y(IX) = Y(O'15') + 3.</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>Y(IX) = Y(1HA) + 3.</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
</tbody>
</table>

When a nondecimal constant is used as an actual argument, the following occurs:

- For binary, octal, and hexadecimal constants, if the value fits in a default integer, that integer kind is used. Otherwise, the smallest integer kind large enough to hold the value is used.
- For Hollerith constants, a numeric data type of sufficient size to hold the length of the constant is assumed.

For example:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Data Type of Constant</th>
<th>Length of Constant (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL APAC(Z'34BC2')</td>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
</tbody>
</table>
When a binary, octal, or hexadecimal constant is used in any other context, the default integer data type is assumed. In the following examples, default integer is INTEGER(4):

<table>
<thead>
<tr>
<th>Statement</th>
<th>Data Type of Constant</th>
<th>Length of Constant (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL APAC('9HABCDEFGHI')</td>
<td>REAL(16)</td>
<td>9</td>
</tr>
</tbody>
</table>

When two typeless constants are used in an operation, they both take default integer type.

When nondecimal constants are not the same length as the length implied by a data type, the following occurs:

- **Binary, octal, and hexadecimal constants**
  - These constants can specify up to 16 bytes of data. When the length of the constant is less than the length implied by the data type, the leftmost digits have a value of zero.
  - When the length of the constant is greater than the length implied by the data type, the constant is truncated on the left. An error results if any nonzero digits are truncated.
  - The Data Type Storage Requirements table lists the number of bytes that each data type requires.

- **Hollerith constants**
  - When the length of the constant is less than the length implied by the data type, blanks are appended to the constant on the right.
  - When the length of the constant is greater than the length implied by the data type, the constant is truncated on the right. If any characters other than blank characters are truncated, a warning occurs.
Each Hollerith character occupies one byte of memory.

**Variables**

A variable is a data object whose value can be changed at any point in a program. A variable can be any of the following:

- A scalar
  
  A *scalar* is a single object that has a single value; it can be of any intrinsic or derived (user-defined) type.

- An array
  
  An *array* is a collection of scalar elements of any intrinsic or derived type. All elements must have the same type and kind parameters.

- A subobject designator
  
  A subobject is part of an object. The following are subobjects:

  - An array element
  - An array section
  - A structure component
  - A character substring

  For example, B(3) is a subobject (array element) designator for array B. A subobject cannot be a variable if its parent object is a constant.

The name of a variable is associated with a single storage location.

Variables are classified by data type, as constants are. The data type of a variable indicates the type of data it contains, including its precision, and implies its storage requirements. When data of any type is assigned to a variable, it is converted to the data type of the variable (if necessary).

A variable is *defined* when you give it a value. A variable can be defined before program execution by a DATA statement or a type declaration statement. During program execution, variables can be defined or redefined in assignment statements and input statements, or undefined (for example, if an I/O error occurs). When a variable is undefined, its value is unpredictable.

When a variable becomes undefined, all variables associated by storage association also become undefined.
An object with subobjects, such as an array, can only be defined when all of its subobjects are defined. Conversely, when at least one of its subobjects are undefined, the object itself, such as an array or derived type, is undefined.

This section also discusses the Data Types of Scalar Variables and Arrays.

**Data Types of Scalar Variables**

The data type of a scalar variable can be explicitly declared in a type declaration statement. If no type is declared, the variable has an implicit data type based on predefined typing rules or definitions in an IMPLICIT statement.

An explicit declaration of data type takes precedence over any implicit type. Implicit type specified in an IMPLICIT statement takes precedence over predefined typing rules.

**Specification of Data Type**

Type declaration statements explicitly specify the data type of scalar variables. For example, the following statements associate VAR1 with an 8-byte complex storage location, and VAR2 with an 8-byte double-precision storage location:

```
COMPLEX(8) VAR1
REAL(8) VAR2
```

You can explicitly specify the data type of a scalar variable only once.

If no explicit data type specification appears, any variable with a name that begins with the letter in the range specified in the IMPLICIT statement becomes the data type of the variable.

Character type declaration statements specify that given variables represent character values with the length specified. For example, the following statements associate the variable names INLINE, NAME, and NUMBER with storage locations containing character data of lengths 72, 12, and 9, respectively:

```
CHARACTER*72 INLINE
CHARACTER NAME*12, NUMBER*9
```

In single subprograms, assumed-length character arguments can be used to process character strings with different lengths. The assumed-length character argument has its length specified with an asterisk, for example:

```
CHARACTER*(*) CHARDUMMY
```

The argument CHARDUMMY assumes the length of the actual argument.
See Also
- Data Types of Scalar Variables
- Type declaration statements
- Assumed-length character arguments
- IMPLICIT statement
- Declaration Statements for Character Types

Implicit Typing Rules

By default, all scalar variables with names beginning with J, K, L, M, or N are assumed to be default integer variables. Scalar variables with names beginning with any other letter are assumed to be default real variables. For example:

<table>
<thead>
<tr>
<th>Real Variables</th>
<th>Integer Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALPHA</td>
<td>JCOUNT</td>
</tr>
<tr>
<td>BETA</td>
<td>ITEM_1</td>
</tr>
<tr>
<td>TOTAL_NUM</td>
<td>NTOTAL</td>
</tr>
</tbody>
</table>

Names beginning with a dollar sign ($) are implicitly INTEGER.

You can override the default data type implied in a name by specifying data type in either an IMPLICIT statement or a type declaration statement.

See Also
- Data Types of Scalar Variables
- Type declaration statements
- IMPLICIT statement

Arrays

An array is a set of scalar elements that have the same type and kind parameters. Any object that is declared with an array specification is an array. Arrays can be declared by using a type declaration statement, or by using a DIMENSION, COMMON, ALLOCATABLE, POINTER, or TARGET statement.

An array can be referenced by element (using subscripts), by section (using a section subscript list), or as a whole. A subscript list (appended to the array name) indicates which array element or array section is being referenced.

A section subscript list consists of subscripts, subscript triplets, or vector subscripts. At least one subscript in the list must be a subscript triplet or vector subscript.
When an array name without any subscripts appears in an intrinsic operation (for example, addition), the operation applies to the whole array (all elements in the array).

An array has the following properties:

- **Data type**
  An array can have any intrinsic or derived type. The data type of an array (like any other variable) is specified in a type declaration statement or implied by the first letter of its name. All elements of the array have the same type and kind parameters. If a value assigned to an individual array element is not the same as the type of the array, it is converted to the array's type.

- **Rank**
  The rank of an array is the number of dimensions in the array. An array can have up to seven dimensions. A rank-one array represents a column of data (a vector), a rank-two array represents a table of data arranged in columns and rows (a matrix), a rank-three array represents a table of data on multiple pages (or planes), and so forth.

- **Bounds**
  Arrays have a lower and upper bound in each dimension. These bounds determine the range of values that can be used as subscripts for the dimension. The value of either bound can be positive, negative, or zero.

  The bounds of a dimension are defined in an array specification.

- **Size**
  The size of an array is the total number of elements in the array (the product of the array's extents).

  The extent is the total number of elements in a particular dimension. It is determined as follows: upper bound - lower bound + 1. If the value of any of an array's extents is zero, the array has a size of zero.

- **Shape**
  The shape of an array is determined by its rank and extents, and can be represented as a rank-one array (vector) where each element is the extent of the corresponding dimension.

  Two arrays with the same shape are said to be **conformable**. A scalar is conformable to an array of any shape.

The name and rank of an array must be specified when the array is declared. The extent of each dimension can be constant, but does not need to be. The extents can vary during program execution if the array is a dummy argument array, an automatic array, an array pointer, or an allocatable array.
A whole array is referenced by the array name. Individual elements in a named array are referenced by a scalar subscript or list of scalar subscripts (if there is more than one dimension). A section of a named array is referenced by a section subscript.

This section also discusses:

- Whole Arrays
- Array Elements
- Array Sections
- Array Constructors

**Examples**

The following are examples of valid array declarations:

```
DIMENSION A(10, 2, 3)        ! DIMENSION statement
ALLOCATABLE B(:, :)          ! ALLOCATABLE statement
POINTER C(:, :, :)           ! POINTER statement
REAL, DIMENSION (2, 5) :: D   ! Type declaration with
```

Consider the following array declaration:

```
INTEGER L(2:11,3)
```

The properties of array L are as follows:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>INTEGER</td>
</tr>
<tr>
<td>Rank</td>
<td>2 (two dimensions)</td>
</tr>
<tr>
<td>Bounds</td>
<td>First dimension: 2 to 11</td>
</tr>
<tr>
<td></td>
<td>Second dimension: 1 to 3</td>
</tr>
<tr>
<td>Size</td>
<td>30; the product of the extents: 10 x 3</td>
</tr>
<tr>
<td>Shape</td>
<td>(/10,3/) (or 10 by 3); a vector of the extents 10 and 3</td>
</tr>
</tbody>
</table>
The following example shows other valid ways to declare this array:

```plaintext
DIMENSION L(2:11,3)
INTEGER, DIMENSION(2:11,3) :: L
COMMON L(2:11,3)
```

The following example shows references to array elements, array sections, and a whole array:

```plaintext
REAL B(10) ! Declares a rank-one array with 10 elements
INTEGER C(5,8) ! Declares a rank-two array with 5 elements in
! dimension one and 8 elements in dimension two
...
B(3) = 5.0 ! Reference to an array element
B(2:5) = 1.0 ! Reference to an array section consisting of
! elements: B(2), B(3), B(4), B(5)
...
C(4,8) = I ! Reference to an array element
C(1:3,3:4) = J ! Reference to an array section consisting of
! elements: C(1,3) C(1,4)
! C(2,3) C(2,4)
! C(3,3) C(3,4)/
B = 99 ! Reference to a whole array consisting of
! elements: B(1), B(2), B(3), B(4), B(5),
! B(6), B(7), B(8), B(9), and B(10)
```

**Whole Arrays**

A **whole array** is a named array; it is either a named constant or a variable. It is referenced by using the array name (without any subscripts).

If a whole array appears in a nonexecutable statement, the statement applies to the entire array. For example:

```plaintext
INTEGER, DIMENSION(2:11,3) :: L ! Specifies the type and
! dimensions of array L
```
If a whole array appears in an executable statement, the statement applies to all of the elements in the array. For example:

```
L = 10 ! The value 10 is assigned to all the elements in array L
WRITE *, L ! Prints all the elements in array L
```

### Array Elements

An *array element* is one of the scalar data items that make up an array. A subscript list (appended to the array or array component) determines which element is being referred to. A reference to an array element takes the following form:

```
array(subscript-list)
```

- `array` is the name of the array.
- `subscript-list` is a list of one or more subscripts separated by commas. The number of subscripts must equal the rank of the array. Each subscript must be a scalar integer (or other numeric) expression with a value that is within the bounds of its dimension.

### Description

Each array element inherits the type, kind type parameter, and certain attributes (INTENT, PARAMETER, and TARGET) of the parent array. An array element cannot inherit the POINTER attribute.

If an array element is of type character, it can be followed by a substring range in parentheses; for example:

```
ARRAY_D(1,2) (1:3) ! Elements are substrings of length 3
```

However, by convention, such an object is considered to be a substring rather than an array element.

The following are some valid array element references for an array declared as REAL B(10,20): B(1,3), B(10,10), and B(5,8).
You can use functions and array elements as subscripts. For example:

```fortran
REAL A(3, 3)
REAL B(3, 3), C(89), R

B(2, 2) = 4.5 ! Assigns the value 4.5 to element B(2, 2)
R = 7.0
C(INT(R)*2 + 1) = 2.0 ! Element 15 of C = 2.0
A(1,2) = B(INT(C(15)), INT(SQRT(R))) ! Element A(1,2) = element B(2,2) = 4.5
```

For information on forms for array specifications, see
Declaration Statements for Arrays.

**Array Element Order**

The elements of an array form a sequence known as array element order. The position of an element in this sequence is its subscript order value.

The elements of an array are stored as a linear sequence of values. A one-dimensional array is stored with its first element in the first storage location and its last element in the last storage location of the sequence. A multidimensional array is stored so that the leftmost subscripts vary most rapidly. This is called the order of subscript progression.
The following figure shows array storage in one, two, and three dimensions:

**Figure 27: Array Storage**

### One-Dimensional Array BRC (6)

<table>
<thead>
<tr>
<th></th>
<th>BRC(1)</th>
<th>2</th>
<th>BRC(2)</th>
<th>3</th>
<th>BRC(3)</th>
<th>4</th>
<th>BRC(4)</th>
<th>5</th>
<th>BRC(5)</th>
<th>6</th>
<th>BRC(6)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><img src="image1.png" alt="Memory Positions" /></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Two-Dimensional Array BAN (3,4)

<table>
<thead>
<tr>
<th></th>
<th>BAN(1,1)</th>
<th>4</th>
<th>BAN(1,2)</th>
<th>7</th>
<th>BAN(1,3)</th>
<th>10</th>
<th>BAN(1,4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><img src="image2.png" alt="Memory Positions" /></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Three-Dimensional Array BOS (3,3,3)

<table>
<thead>
<tr>
<th></th>
<th>BOS(1,1,1)</th>
<th>4</th>
<th>BOS(1,2,1)</th>
<th>7</th>
<th>BOS(1,3,1)</th>
<th>18</th>
<th>BOS(3,3,2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><img src="image3.png" alt="Memory Positions" /></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
For example, in two-dimensional array BAN, element BAN(1,2) has a subscript order value of 4; in three-dimensional array BOS, element BOS(1,1,1) has a subscript order value of 1.

In an array section, the subscript order of the elements is their order within the section itself. For example, if an array is declared as B(20), the section B(4:19:4) consists of elements B(4), B(8), B(12), and B(16). The subscript order value of B(4) in the array section is 1; the subscript order value of B(12) in the section is 3.

**Array Sections**

An *array section* is a portion of an array that is an array itself. It is an array subobject. A section subscript list (appended to the array or array component) determines which portion is being referred to. A reference to an array section takes the following form:

```
array(sect-subscript-list)
```

- **array** is the name of the array.
- **sect-subscript-list** is a list of one or more section subscripts (subscripts, subscript triplets, or vector subscripts) indicating a set of elements along a particular dimension.

  At least one of the items in the section subscript list must be a subscript triplet or vector subscript. A subscript triplet specifies array elements in increasing or decreasing order at a given stride. A vector subscript specifies elements in any order.

  Each subscript and subscript triplet must be a scalar integer (or other numeric) expression. Each vector subscript must be a rank-one integer expression.

**Description**

If no section subscript list is specified, the rank and shape of the array section is the same as the parent array.

Otherwise, the rank of the array section is the number of vector subscripts and subscript triplets that appear in the list. Its shape is a rank-one array where each element is the number of integer values in the sequence indicated by the corresponding subscript triplet or vector subscript.
If any of these sequences is empty, the array section has a size of zero. The subscript order of the elements of an array section is that of the array object that the array section represents.

Each array section inherits the type, kind type parameter, and certain attributes (INTENT, PARAMETER, and TARGET) of the parent array. An array section cannot inherit the POINTER attribute.

If an array (or array component) is of type character, it can be followed by a substring range in parentheses. Consider the following declaration:

```fortran
CHARACTER(LEN=15) C(10,10)
```

In this case, an array section referenced as `C(:,:) (1:3)` is an array of shape `(10,10)`, whose elements are substrings of length 3 of the corresponding elements of C.

The following shows valid references to array sections. Note that the syntax `(/.../)` denotes an array constructor.

```fortran
REAL, DIMENSION(20) :: B
...
PRINT *, B(2:20:5) ! The section consists of elements
! B(2), B(7), B(12), and B(17)
K = (/3, 1, 4/)
B(K) = 0.0 ! Section B(K) is a rank-one array with shape (3) and
! size 3. (0.0 is assigned to B(1), B(3), and B(4).)
```

Subscript Triplets

A subscript triplet is a set of three values representing the lower bound of the array section, the upper bound of the array section, and the increment (stride) between them. It takes the following form:

\[
\text{[first-bound]} : \text{[last-bound]} [:\text{stride}]
\]

*first-bound*  
Is a scalar integer (or other numeric) expression representing the first value in the subscript sequence. If omitted, the declared lower bound of the dimension is used.

*last-bound*  
Is a scalar integer (or other numeric) expression representing the last value in the subscript sequence. If omitted, the declared upper bound of the dimension is used.

When indicating sections of an assumed-size array, this subscript *must* be specified.

*stride*  
Is a scalar integer (or other numeric) expression representing the increment between successive subscripts in the sequence. It must have a nonzero value. If it is omitted, it is assumed to be 1.

The stride has the following effects:

- **If the stride is positive**, the subscript range starts with the first subscript and is incremented by the value of the stride, until the largest value less than or equal to the second subscript is attained.

  For example, if an array has been declared as B(6,3,2), the array section specified as B(2:4,1:2,2) is a rank-two array with shape (3,2) and size 6. It consists of the following six elements:

  \[
  \begin{array}{cc}
  \text{B(2,1,2)} & \text{B(2,2,2)} \\
  \text{B(3,1,2)} & \text{B(3,2,2)} \\
  \text{B(4,1,2)} & \text{B(4,2,2)} \\
  \end{array}
  \]

  If the first subscript is greater than the second subscript, the range is empty.

- **If the stride is negative**, the subscript range starts with the value of the first subscript and is decremented by the absolute value of the stride, until the smallest value greater than or equal to the second subscript is attained.

  For example, if an array has been declared as A(15), the array section specified as A(10:3:-2) is a rank-one array with shape (4) and size 4. It consists of the following four elements:

  \[
  \begin{array}{c}
  \text{A(10)} \\
  \text{A(8)} \\
  \text{A(6)} \\
  \text{A(4)} \\
  \end{array}
  \]
If the second subscript is greater than the first subscript, the range is empty.

If a range specified by the stride is empty, the array section has a size of zero.

A subscript in a subscript triplet need not be within the declared bounds for that dimension if all values used to select the array elements are within the declared bounds. For example, if an array has been declared as A(15), the array section specified as A(4:16:10) is valid. The section is a rank-one array with shape (2) and size 2. It consists of elements A(4) and A(14).

If the subscript triplet does not specify bounds or stride, but only a colon (:) the entire declared range for the dimension is used.

If you leave out all subscripts, the section defaults to the entire extent in that dimension. For example:

```fortran
REAL A(10)
A(1:5:2) = 3.0 ! Sets elements A(1), A(3), A(5) to 3.0
A(:5:2) = 3.0 ! Same as the previous statement
             ! because the lower bound defaults to 1
A(2::3) = 3.0 ! Sets elements A(2), A(5), A(8) to 3.0
             ! The upper bound defaults to 10
A(7:9) = 3.0 ! Sets elements A(7), A(8), A(9) to 3.0
             ! The stride defaults to 1
A(:) = 3.0  ! Same as A = 3.0; sets all elements of
             ! A to 3.0
```

**See Also**

- Array Sections
- Array Sections
- Vector Subscripts

A **vector subscript** is a one-dimensional (rank one) array of integer values (within the declared bounds for the dimension) that selects a section of a whole (parent) array. The elements in the section do not have to be in order and the section can contain duplicate values.

For example, A is a rank-two array of shape (4,6). B and C are rank-one arrays of shape (2) and (3), respectively, with the following values:

```fortran
B = (/1,4/) ! Syntax (/.../) denotes an array constructor
C = (/2,1,1/) ! This constructor produces a many-one array section
```
Array section \(A(3,B)\) consists of elements \(A(3,1)\) and \(A(3,4)\). Array section \(A(C,1)\) consists of elements \(A(2,1), A(1,1),\) and \(A(1,1)\). Array section \(A(B,C)\) consists of the following elements:

\[
\begin{array}{ccc}
A(1,2) & A(1,1) & A(1,1) \\
A(4,2) & A(4,1) & A(4,1)
\end{array}
\]

An array section with a vector subscript that has two or more elements with the same value is called a \textit{many-one array section}. For example:

```fortran
REAL A(3, 3), B(4)
INTEGER K(4)

! Vector K has repeated values
K = (/3, 1, 1, 2/)
! Sets all elements of A to 5.0
A = 5.0
B = A(3, K)
```

The array section \(A(3,K)\) consists of the elements:

\[
\begin{array}{cccc}
A(3, 3) & A(3, 1) & A(3, 1) & A(3, 2)
\end{array}
\]

A many-one section must not appear on the left of the equal sign in an assignment statement, or as an input item in a READ statement.

The following assignments to \(C\) also show examples of vector subscripts:

```fortran
INTEGER A(2), B(2), C(2)

... 
B = (/1,2/) 
C(B) = A(B) 
C = A(/1,2/))
```

An array section with a vector subscript must not be any of the following:

- An internal file
- An actual argument associated with a dummy array that is defined or redefined (if the \text{INTENT} attribute is specified, it must be \text{INTENT(IN)})
- The target in a pointer assignment statement

If the sequence specified by the vector subscript is empty, the array section has a size of zero.

Array Constructors

An array constructor can be used to create and assign values to rank-one arrays (and array constants). An array constructor takes the following form:

\[
(ac-value-list)
\]

\(ac-value-list\) is a list of one or more expressions or implied-DO loops. Each \(ac-value\) must have the same type and kind parameters, and be separated by commas.

An implied-DO loop in an array constructor takes the following form:

\[
(ac-value-list, do-variable = expr1, expr2 [,expr3])
\]

\(do-variable\) is the name of a scalar integer variable. Its scope is that of the implied-DO loop.

\(expr\) is a scalar integer expression. The \(expr1\) and \(expr2\) specify a range of values for the loop; \(expr3\) specifies the stride. The \(expr3\) must be a nonzero value; if it is omitted, it is assumed to be 1.

Description

The array constructed has the same type as the \(ac-value-list\) expressions.

If the sequence of values specified by the array constructor is empty (an empty array expression or the implied-DO loop produces no values), the rank-one array has a size of zero.

An \(ac-value\) is interpreted as follows:

<table>
<thead>
<tr>
<th>Form of (ac-value)</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A scalar expression</td>
<td>Its value is an element of the new array.</td>
</tr>
<tr>
<td>An array expression</td>
<td>The values of the elements in the expression (in array element order) are the corresponding sequence of elements in the new array.</td>
</tr>
</tbody>
</table>
Form of ac-value | Result
---|---
An implied-DO loop | It is expanded to form a list of array elements under control of the DO variable (like a DO construct).

The following shows the three forms of an ac-value:

- $C_1 = (4, 8, 7, 6)$  
  ! A scalar expression
- $C_2 = (B(I, 1:5), B(I:J, 7:9))$  
  ! An array expression
- $C_3 = (I, I=1, 4)$  
  ! An implied-DO loop

You can also mix these forms, for example:

- $C_4 = (4, A(1:5), (I, I=1, 4), 7)$

If every expression in an array constructor is a constant expression, the array constructor is a constant expression.

If the expressions are of type character, Fortran 95/90 requires each expression to have the same character length.

However, Intel Fortran allows the character expressions to be of different character lengths. The length of the resultant character array is the maximum of the lengths of the individual character expressions. For example:

```fortran
print *, len ( ('a', 'ab', 'abc', 'd') )
print *, '++' // ('a', 'ab', 'abc', 'd') // '--'
```

This causes the following to be displayed:

```
3
++a ----ab ----abc-----d --
```

If an implied-DO loop is contained within another implied-DO loop (nested), they cannot have the same DO variable (do-variable).

To define arrays of more than one dimension, use the `RESHAPE` intrinsic function.

The following are alternative forms for array constructors:
Square brackets (instead of parentheses and slashes) to enclose array constructors; for example, the following two array constructors are equivalent:

```fortran
INTEGER C(4)
C = (/4,8,7,6/)
C = [4,8,7,6]
```

A colon-separated triplet (instead of an implied-DO loop) to specify a range of values and a stride; for example, the following two array constructors are equivalent:

```fortran
INTEGER D(3)
D = (/1:5:2/) ! Triplet form
D = (/ (I, I=1, 5, 2) //) ! implied-DO loop form
```

**Examples**

The following example shows an array constructor using an implied-DO loop:

```fortran
INTEGER ARRAY_C(10)
ARRAY_C = (/ (I, I=30, 48, 2) //)
```

The values of ARRAY_C are the even numbers 30 through 48.

Implied-DO expressions and values can be mixed in the value list of an array constructor. For example:

```fortran
INTEGER A(10)
A = (/ 1, 0, (I, I = -1, -6, -1), -7, -8 //)
```

This example sets the elements of A to the values, in order, 1, 0, -1, -2, -3, -4, -5, -6, -7, -8.

The following example shows an array constructor of derived type that uses a structure constructor:

```fortran
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=30) NAME
END TYPE EMPLOYEE

TYPE(EMPLOYEE) CC_4T(4)
CC_4T = (/EMPLOYEE(2732,"JONES"), EMPLOYEE(0217,"LEE"), &

          EMPLOYEE(1889,"RYAN"), EMPLOYEE(4339,"EMERSON") //)
```
The following example shows how the RESHAPE intrinsic function can be used to create a multidimensional array:

\[ E = (\begin{array}{c} 2.3, 4.7, 6.6 \end{array}) \]

\[ D = \text{RESHAPE}(\text{SOURCE} = (\begin{array}{c} 3.5, (\begin{array}{c} 2.0, 1.0 \end{array}), E \end{array}), \text{SHAPE} = (\begin{array}{c} 2, 3 \end{array})) \]

\[ D \] is a rank-two array with shape (2,3) containing the following elements:

\[
\begin{array}{ccc}
3.5 & 1.0 & 4.7 \\
2.0 & 2.3 & 6.6 \\
\end{array}
\]

The following shows another example:

```
INTEGER B(2,3), C(8)
! Assign values to a (2,3) array.
B = \text{RESHAPE}(\begin{array}{c} 1, 2, 3, 4, 5, 6 \end{array}), (\begin{array}{c} 2, 3 \end{array}))
! Convert B to a vector before assigning values to vector C.
C = (\begin{array}{c} 0, \text{RESHAPE}(B, (\begin{array}{c} 6 \end{array})), 7 \end{array})
```

Expressions and Assignment Statements

This section contains information on expressions and assignment statements.

Expressions

An expression represents either a data reference or a computation, and is formed from operators, operands, and parentheses. The result of an expression is either a scalar value or an array of scalar values.

If the value of an expression is of intrinsic type, it has a kind type parameter. (If the value is of intrinsic type CHARACTER, it also has a length parameter.) If the value of an expression is of derived type, it has no kind type parameter.

An operand is a scalar or array. An operator can be either intrinsic or defined. An intrinsic operator is known to the compiler and is always available to any program unit. A defined operator is described explicitly by a user in a function subprogram and is available to each program unit that uses the subprogram.

The simplest form of an expression (a primary) can be any of the following:

- A constant; for example, 4.2
- A subobject of a constant; for example, 'LMNOP' (2:4)
- A variable; for example, VAR_1
- A structure constructor; for example, EMPLOYEE(3472, "JOHN DOE")
- An array constructor; for example, (/12.0,16.0/)
- A function reference; for example, COS(X)
- Another expression in parentheses; for example, (I+5)

Any variable or function reference used as an operand in an expression must be defined at the time the reference is executed. If the operand is a pointer, it must be associated with a target object that is defined. An integer operand must be defined with an integer value rather than a statement label value. All of the characters in a character data object reference must be defined.

When a reference to an array or an array section is made, all of the selected elements must be defined. When a structure is referenced, all of the components must be defined.
In an expression that has intrinsic operators with an array as an operand, the operation is performed on each element of the array. In expressions with more than one array operand, the arrays must be conformable (they must have the same shape). The operation is applied to corresponding elements of the arrays, and the result is an array of the same shape (the same rank and extents) as the operands.

In an expression that has intrinsic operators with a pointer as an operand, the operation is performed on the value of the target associated with the pointer.

For defined operators, operations on arrays and pointers are determined by the procedure defining the operation.

A scalar is conformable with any array. If one operand of an expression is an array and another operand is a scalar, it is as if the value of the scalar were replicated to form an array of the same shape as the array operand. The result is an array of the same shape as the array operand.

The following sections describe numeric, character, relational, and logical expressions; defined operations; a summary of operator precedence; and initialization and specification expressions.

**Numeric Expressions**

Numeric expressions express numeric computations, and are formed with numeric operands and numeric operators. The evaluation of a numeric operation yields a single numeric value. The term numeric includes logical data, because logical data is treated as integer data when used in a numeric context. The default for .TRUE. is -1; .FALSE. is 0. Note that the default can change if compiler option fpscomp logicals is used.

Numeric operators specify computations to be performed on the values of numeric operands. The result is a scalar numeric value or an array whose elements are scalar numeric values. The following are numeric operators:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>**</td>
<td>Exponentiation</td>
</tr>
<tr>
<td>*</td>
<td>Multiplication</td>
</tr>
<tr>
<td>/</td>
<td>Division</td>
</tr>
<tr>
<td>+</td>
<td>Addition or unary plus (identity)</td>
</tr>
<tr>
<td>-</td>
<td>Subtraction or unary minus (negation)</td>
</tr>
</tbody>
</table>
Unary operators operate on a single operand. Binary operators operate on a pair of operands. The plus and minus operators can be unary or binary. When they are unary operators, the plus or minus operators precede a single operand and denote a positive (identity) or negative (negation) value, respectively. The exponentiation, multiplication, and division operators are binary operators.

Valid numeric operations must have results that are defined by the arithmetic used by the processor. For example, raising a negative-valued base to a real power is invalid.

Numeric expressions are evaluated in an order determined by a precedence associated with each operator, as follows (see also Summary of Operator Precedence):

<table>
<thead>
<tr>
<th>Operator</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>**</td>
<td>Highest</td>
</tr>
<tr>
<td>* and /</td>
<td></td>
</tr>
<tr>
<td>Unary + and -</td>
<td></td>
</tr>
<tr>
<td>Binary + and -</td>
<td>Lowest</td>
</tr>
</tbody>
</table>

Operators with equal precedence are evaluated in left-to-right order. However, exponentiation is evaluated from right to left. For example, A**B**C is evaluated as A**(B**C). B**C is evaluated first, then A is raised to the resulting power.

Normally, two operators cannot appear together. However, Intel® Fortran allows two consecutive operators if the second operator is a plus or minus.

**Examples**

In the following example, the exponentiation operator is evaluated first because it takes precedence over the multiplication operator:

A**B*C is evaluated as (A**B) *C

Ordinarily, the exponentiation operator would be evaluated first in the following example. However, because Intel Fortran allows the combination of the exponentiation and minus operators, the exponentiation operator is not evaluated until the minus operator is evaluated:

A**-B*C is evaluated as A** (~ (B*C) )

Note that the multiplication operator is evaluated first, since it takes precedence over the minus operator.
When consecutive operators are used with constants, the unary plus or minus before the constant is treated the same as any other operator. This can produce unexpected results. In the following example, the multiplication operator is evaluated first, since it takes precedence over the minus operator:

\[ \frac{x}{-15.0 \times y} \text{ is evaluated as } \frac{x}{-(15.0 \times y)} \]

**Using Parentheses in Numeric Expressions**

You can use parentheses to force a particular order of evaluation. When part of an expression is enclosed in parentheses, that part is evaluated first. The resulting value is used in the evaluation of the remainder of the expression.

In the following examples, the numbers below the operators indicate a possible order of evaluation. Alternative evaluation orders are possible in the first three examples because they contain operators of equal precedence that are not enclosed in parentheses. In these cases, the compiler is free to evaluate operators of equal precedence in any order, as long as the result is the same as the result gained by the algebraic left-to-right order of evaluation.

\[
4 + 3 \times 2 - 6/2 = 7
\]
\[
2 \quad 1 \quad 4 \quad 3
\]
\[
(4 + 3) \times 2 - 6/2 = 11
\]
\[
1 \quad 2 \quad 4 \quad 3
\]
\[
(4 + 3 \times 2 - 6)/2 = 2
\]
\[
2 \quad 1 \quad 3 \quad 4
\]
\[
((4 + 3) \times 2 - 6)/2 = 4
\]
\[
1 \quad 2 \quad 3 \quad 4
\]

Expressions within parentheses are evaluated according to the normal order of precedence. In expressions containing nested parentheses, the innermost parentheses are evaluated first.

Nonessential parentheses do not affect expression evaluation, as shown in the following example:

\[ 4 + (3 \times 2) - (6/2) \]
However, using parentheses to specify the evaluation order is often important in high-accuracy numerical computations. In such computations, evaluation orders that are algebraically equivalent may not be computationally equivalent when processed by a computer (because of the way intermediate results are rounded off).

Parentheses can be used in argument lists to force a given argument to be treated as an expression, rather than as the address of a memory item.

**Data Type of Numeric Expressions**

If every operand in a numeric expression is of the same data type, the result is also of that type.

If operands of different data types are combined in an expression, the evaluation of that expression and the data type of the resulting value depend on the ranking associated with each data type. The following table shows the ranking assigned to each data type:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Ranking</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL(1) and BYTE</td>
<td>Lowest</td>
</tr>
<tr>
<td>LOGICAL(2)</td>
<td>.</td>
</tr>
<tr>
<td>LOGICAL(4)</td>
<td>.</td>
</tr>
<tr>
<td>LOGICAL(8)</td>
<td>.</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>.</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>.</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>.</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>.</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>.</td>
</tr>
<tr>
<td>REAL(8)(^1)</td>
<td>.</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>.</td>
</tr>
<tr>
<td>COMPLEX(4)</td>
<td>.</td>
</tr>
<tr>
<td>COMPLEX(8)(^2)</td>
<td>.</td>
</tr>
<tr>
<td>COMPLEX(16)</td>
<td>Highest</td>
</tr>
</tbody>
</table>
The data type of the value produced by an operation on two numeric operands of different data types is the data type of the highest-ranking operand in the operation. For example, the value resulting from an operation on an integer and a real operand is of real type. However, an operation involving a COMPLEX(4) or COMPLEX(8) data type and a DOUBLE PRECISION data type produces a COMPLEX(8) result.

The data type of an expression is the data type of the result of the last operation in that expression, and is determined according to the following conventions:

- **Integer operations:** Integer operations are performed only on integer operands. (Logical entities used in a numeric context are treated as integers.) In integer arithmetic, any fraction resulting from division is truncated, not rounded. For example, the result of \( \frac{9}{10} \) is 0, not 1.

- **Real operations:** Real operations are performed only on real operands or combinations of real, integer, and logical operands. Any integer operands present are converted to real data type by giving each a fractional part equal to zero. The expression is then evaluated using real arithmetic. However, in the statement \( Y = (I /J) \times X \), an integer division operation is performed on I and J, and a real multiplication is performed on that result and X.

If one operand is a higher-precision real (REAL(8) or REAL(16)) type, the other operand is converted to that higher-precision real type before the expression is evaluated.

When a single-precision real operand is converted to a double-precision real operand, low-order binary digits are set to zero. This conversion does not increase accuracy; conversion of a decimal number does not produce a succession of decimal zeros. For example, a REAL variable having the value 0.3333333 is converted to approximately \( 0.3333333314651184 \times 10^1 \). It is not converted to either \( 0.3333333000000000 \times 10^1 \) or \( 0.3333333333333333 \times 10^1 \).

- **Complex operations:** In operations that contain any complex operands, integer operands are converted to real type, as previously described. The resulting single-precision or double-precision operand is designated as the real part of a complex number and the imaginary part is assigned a value of zero. The expression is then evaluated using complex arithmetic and the resulting value is of complex type. Operations involving a COMPLEX(4) or COMPLEX(8) operand and a DOUBLE PRECISION operand are performed as COMPLEX(8) operations; the DOUBLE PRECISION operand is not rounded.
These rules also generally apply to numeric operations in which one of the operands is a constant. However, if a real or complex constant is used in a higher-precision expression, additional precision will be retained for the constant. The effect is as if a DOUBLE PRECISION (REAL(8)) or REAL(16) representation of the constant were given. For example, the expression $1.0D0 + 0.3333333$ is treated as if it is $1.0D0 + \text{db}1e(0.3333333)$.

**Character Expressions**

A character expression consists of a character operator (//) that concatenates two operands of type character. The evaluation of a character expression produces a single value of that type.

The result of a character expression is a character string whose value is the value of the left character operand concatenated to the value of the right operand. The length of a character expression is the sum of the lengths of the values of the operands. For example, the value of the character expression `'AB'//'CDE'` is `'ABCDE'`, which has a length of five.

Parentheses do not affect the evaluation of a character expression; for example, the following character expressions are equivalent:

- `( 'ABC' //'DE' ) //'F'`
- `'ABC' //'DE' //'F'`
- `'ABC' //'DE' //'F'`

Each of these expressions has the value `' ABCDEF'`.

If a character operand in a character expression contains blanks, the blanks are included in the value of the character expression. For example, `'ABC  //'DE//'F '` has a value of `'ABC D E F '`.

**Relational Expressions**

A *relational expression* consists of two or more expressions whose values are compared to determine whether the relationship stated by the relational operator is satisfied. The following are relational operators:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Relationship</th>
</tr>
</thead>
<tbody>
<tr>
<td>.LT. or &lt;</td>
<td>Less than</td>
</tr>
<tr>
<td>.LE. or &lt;=</td>
<td>Less than or equal to</td>
</tr>
<tr>
<td>.EQ. or =</td>
<td>Equal to</td>
</tr>
<tr>
<td>.NE. or /=</td>
<td>Not equal to</td>
</tr>
</tbody>
</table>

1823
RelationshipOperator
Greater than.GT. or >
Greater than or equal to.GE. or >=
The result of the relational expression is .TRUE. if the relation specified by the operator is satisfied; the result is .FALSE. if the relation specified by the operator is not satisfied.

Relational operators are of equal precedence. Numeric operators and the character operator // have a higher precedence than relational operators.

In a numeric relational expression, the operands are numeric expressions. Consider the following example:

APPLE+PEACH > PEAR+ORANGE

This expression states that the sum of APPLE and PEACH is greater than the sum of PEAR and ORANGE. If this relationship is valid, the value of the expression is .TRUE.; if not, the value is .FALSE.

Operands of type complex can only be compared using the equal operator (= = or .EQ.) or the not equal operator (/= or .NE.). Complex entities are equal if their corresponding real and imaginary parts are both equal.

In a character relational expression, the operands are character expressions. In character relational expressions, less than (< or .LT.) means the character value precedes in the ASCII collating sequence, and greater than (> or .GT.) means the character value follows in the ASCII collating sequence. For example:

'AB'/'ZZZ' .LT. 'CCCCC'

This expression states that 'ABZZZ' is less than 'CCCCC'. In this case, the relation specified by the operator is satisfied, so the result is .TRUE.

Character operands are compared one character at a time, in order, starting with the first character of each operand. If the two character operands are not the same length, the shorter one is padded on the right with blanks until the lengths are equal; for example:

'ABC' .EQ. 'ABC'

'AB' .LT. 'C'

The first relational expression has the value .TRUE. even though the lengths of the expressions are not equal, and the second has the value .TRUE. even though 'AB' is longer than 'C'.

A relational expression can compare two numeric expressions of different data types. In this case, the value of the expression with the lower-ranking data type is converted to the higher-ranking data type before the comparison is made.

- Expressions
- Data Type of Numeric Expressions

**Logical Expressions**

A logical expression consists of one or more logical operators and logical, numeric, or relational operands. The following are logical operators:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Example</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>.AND.</td>
<td>A .AND. B</td>
<td>Logical conjunction: the expression is true if both A and B are true.</td>
</tr>
<tr>
<td>.OR.</td>
<td>A .OR. B</td>
<td>Logical disjunction (inclusive OR): the expression is true if either A, B, or both, are true.</td>
</tr>
<tr>
<td>.NEQV.</td>
<td>A .NEQV. B</td>
<td>Logical inequivalence (exclusive OR): the expression is true if either A or B is true, but false if both are true.</td>
</tr>
<tr>
<td>.XOR.</td>
<td>A .XOR. B</td>
<td>Same as .NEQV.</td>
</tr>
<tr>
<td>.EQV.</td>
<td>A .EQV. B</td>
<td>Logical equivalence: the expression is true if both A and B are true, or both are false.</td>
</tr>
<tr>
<td>.NOT.¹</td>
<td>.NOT. A</td>
<td>Logical negation: the expression is true if A is false and false if A is true.</td>
</tr>
</tbody>
</table>

¹ .NOT. is a unary operator.

Periods cannot appear consecutively except when the second operator is .NOT. For example, the following logical expression is valid:

\[ A+B/(A-1) \ .AND. \ .NOT. \ D+B/(D-1) \]
Data Types Resulting from Logical Operations

Logical operations on logical operands produce single logical values (.TRUE. or .FALSE.) of logical type.

Logical operations on integers produce single values of integer type. The operation is carried out bit-by-bit on corresponding bits of the internal (binary) representation of the integer operands.

Logical operations on a combination of integer and logical values also produce single values of integer type. The operation first converts logical values to integers, then operates as it does with integers.

Logical operations cannot be performed on other data types.

Evaluation of Logical Expressions

Logical expressions are evaluated according to the precedence of their operators. Consider the following expression:

\[ A \times B + C \times ABC = X \times Y + DM/ZZ \land \lnot K \times B > TT \]

This expression is evaluated in the following sequence:

\[ (((A \times B) + (C \times ABC)) = ((X \times Y) + (DM/ZZ))) \land \lnot ((K \times B) > TT)) \]

As with numeric expressions, you can use parentheses to alter the sequence of evaluation.

When operators have equal precedence, the compiler can evaluate them in any order, as long as the result is the same as the result gained by the algebraic left-to-right order of evaluation (except for exponentiation, which is evaluated from right to left).

You should not write logical expressions whose results might depend on the evaluation order of subexpressions. The compiler is free to evaluate subexpressions in any order. In the following example, either \( (A(I)+1.0) \) or \( B(I) \times 2.0 \) could be evaluated first:

\[ (A(I)+1.0) \land (B(I) \times 2.0) \]

Some subexpressions might not be evaluated if the compiler can determine the result by testing other subexpressions in the logical expression. Consider the following expression:

\[ A \land (F(X,Y) \land 2.0) \land B \]

If the compiler evaluates \( A \) first, and \( A \) is false, the compiler might determine that the expression is false and might not call the subprogram \( F(X,Y) \).

- Expressions
• **Summary of Operator Precedence**

**Defined Operations**

When operators are defined for functions, the functions can then be referenced as defined operations.

The operators are defined by using a generic interface block specifying OPERATOR, followed by the defined operator (in parentheses).

A defined operation is not an intrinsic operation. However, you can use a defined operation to extend the meaning of an intrinsic operation.

For defined unary operations, the function must contain one argument. For defined binary operations, the function must contain two arguments.

Interpretation of the operation is provided by the function that defines the operation.

A Fortran 95/90 defined operator can contain up to 31 letters, and is enclosed in periods (.). Its name cannot be the same name as any of the following:

- The intrinsic operators (.NOT., .AND., .OR., .XOR., .EQV., .NEQV., .EQ., .NE., .GT., .GE., .LT., and .LE.)
- The logical literal constants (.TRUE. or .FALSE.)

An intrinsic operator can be followed by a defined unary operator.

The result of a defined operation can have any type. The type of the result (and its value) must be specified by the defining function.

**Examples**

The following examples show expressions containing defined operators:

```
.COMPLEMENT. A
X .PLUS. Y .PLUS. Z
M * .MINUS. N
```

## Initialization and Specification Expressions

A constant expression contains intrinsic operations and parts that are all constants. An **initialization expression** is a constant expression that is evaluated when a program is compiled. A **specification expression** is a scalar, integer expression that is restricted to declarations of array bounds and character lengths.

Initialization and specification expressions can appear in specification statements, with some restrictions.

### Initialization Expressions

An initialization expression must evaluate at compile time to a constant. It is used to specify an initial value for an entity.
In an initialization expression, each operation is intrinsic and each operand is one of the following:

- A constant or subobject of a constant
- An array constructor where each element and the bounds and strides of each implied-DO, are expressions whose primaries are initialization expressions
- A structure constructor whose components are initialization expressions
- An elemental intrinsic function reference of type integer or character, whose arguments are initialization expressions of type integer or character
- A reference to one of the following inquiry functions:

  | BIT_SIZE | MAXEXPONENT |
  | DIGITS   | PRECISION   |
  | EPSILON  | RADIX       |
  | HUGE     | RANGE       |
  | ILEN     | SHAPE       |
  | KIND     | SIZE        |
  | LBOUND   | TINY        |
  | LEN      | UBOUND      |
  | MAXEXPONENT       |

Each function argument must be one of the following:

- An initialization expression
- A variable whose kind type parameter and bounds are not assumed or defined by an ALLOCATE statement, pointer assignment, or an expression that is not an initialization expression
- A reference to one of the following transformational functions (each argument must be an initialization expression):

  | REPEAT     | SELECTED_REAL_KIND |
  | RESHAPE    | TRANSFER           |
  | SELECTED_CHAR_KIND | TRIM               |
SELECTED_INT_KIND

- A reference to the transformational function NULL
- An implied-DO variable within an array constructor where the bounds and strides of the corresponding implied-DO are initialization expressions
- Another initialization expression enclosed in parentheses

Each subscript, section subscript, and substring starting and ending point must be an initialization expression.

In an initialization expression, the exponential operator (***) must have a power of type integer.

If an initialization expression invokes an inquiry function for a type parameter or an array bound of an object, the type parameter or array bound must be specified in a prior specification statement (or to the left of the inquiry function in the same statement).

**Examples**

**Table 567: Valid Initialization (Constant) Expressions**

-1 + 3

SIZE(B) ! B is a named constant

7_2

INT(J, 4) ! J is a named constant

SELECTED_INT_KIND (2)

**Table 568: Invalid Initialization (Constant) Expressions**

SUM(A) Not an allowed function.

A/4.1 - K**1.2 Exponential does not have integer power (A and K are named constants).

HUGE(4.0) Argument is not an integer.

**See Also**

- Initialization and Specification Expressions
- Array constructors
• **Structure constructors**
• **Intrinsic procedures**

**Specification Expressions**

A specification expression is a restricted expression that is of type integer and has a scalar value. This type of expression appears only in the declaration of array bounds and character lengths.

In a restricted expression, each operation is intrinsic and each operand is one of the following:

- A constant or subobject of a constant
- A variable that is one of the following:
  - A dummy argument that does not have the OPTIONAL or INTENT (OUT) attribute (or the subobject of such a variable)
  - In a common block (or the subobject of such a variable)
  - Made accessible by use or host association (or the subobject of such a variable)
- A structure constructor whose components are restricted expressions
- An implied-DO variable within an array constructor, where the bounds and strides of the corresponding implied-DO are restricted expressions
- A reference to one of the following inquiry functions:

<table>
<thead>
<tr>
<th>Inquiry Function</th>
<th>Argument Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIT_SIZE</td>
<td>MINEXPONENT</td>
</tr>
<tr>
<td>DIGITS</td>
<td>PRECISION</td>
</tr>
<tr>
<td>EPSILON</td>
<td>RADIX</td>
</tr>
<tr>
<td>HUGE</td>
<td>RANGE</td>
</tr>
<tr>
<td>ILEN</td>
<td>SHAPE</td>
</tr>
<tr>
<td>KIND</td>
<td>SIZE</td>
</tr>
<tr>
<td>LBOUND</td>
<td>SIZEOF</td>
</tr>
<tr>
<td>LEN</td>
<td>TINY</td>
</tr>
<tr>
<td>MAXEXPONENT</td>
<td>UBOUND</td>
</tr>
</tbody>
</table>

Each function argument must be one of the following:

- A restricted expression
A variable whose properties inquired about are not dependent on the upper bound of the last dimension of an assumed-size array, are not defined by an expression that is not a restricted expression, or are not definable by an ALLOCATE or pointer assignment statement.

- A reference to any other intrinsic function where each argument is a restricted expression.
- A reference to a specification function where each argument is a restricted expression
- An array constructor where each element and the bounds and strides of each implied-DO, are expressions whose primaries are restricted expressions
- Another restricted expression enclosed in parentheses

Each subscript, section subscript, and substring starting and ending point must be a restricted expression.

Specification functions can be used in specification expressions to indicate the attributes of data objects. A specification function is a pure function. It cannot have a dummy procedure argument or be any of the following:

- An intrinsic function
- An internal function
- A statement function
- Defined as RECURSIVE

A variable in a specification expression must have its type and type parameters (if any) specified in one of the following ways:

- By a previous declaration in the same scoping unit
- By the implicit typing rules currently in effect for the scoping unit
- By host or use association

If a variable in a specification expression is typed by the implicit typing rules, its appearance in any subsequent type declaration statement must confirm the implied type and type parameters.

If a specification expression invokes an inquiry function for a type parameter or an array bound of an object, the type parameter or array bound must be specified in a prior specification statement (or to the left of the inquiry function in the same statement).

In a specification expression, the number of arguments for a function reference is limited to 255.
Examples
The following shows valid specification expressions:

\[
\text{MAX}(I) + J \quad \text{! I and J are scalar integer variables}
\]

\[
\text{UBOUND(ARRAY}_{B},20) \quad \text{! ARRAY}_{B} \text{ is an assumed-shape dummy array}
\]

Assignment Statements

An assignment statement causes variables to be defined or redefined. This section describes the following kinds of assignment statements: intrinsic, defined, pointer, masked array (WHERE), and element array (FORALL).

The ASSIGN statement assigns a label to an integer variable. It is discussed elsewhere.

Intrinsic Assignments

Intrinsic assignment is used to assign a value to a nonpointer variable. In the case of pointers, intrinsic assignment is used to assign a value to the target associated with the pointer variable. The value assigned to the variable (or target) is determined by evaluation of the expression to the right of the equal sign.

An intrinsic assignment statement takes the following form:

\[
\text{variable} = \text{expression}
\]

\text{variable} \quad \text{Is the name of a scalar or array of intrinsic or derived type (with no defined assignment). The array cannot be an assumed-size array, and neither the scalar nor the array can be declared with the PARAMETER or INTENT(IN) attribute.}

\text{expression} \quad \text{Is of intrinsic type or the same derived type as variable. Its shape must conform with variable. If necessary, it is converted to the same type and kind as variable.}
Description

Before a value is assigned to the variable, the expression part of the assignment statement and any expressions within the variable are evaluated. No definition of expressions in the variable can affect or be affected by the evaluation of the expression part of the assignment statement.

**NOTE.** When the run-time system assigns a value to a scalar integer or character variable and the variable is shorter than the value being assigned, the assigned value may be truncated and significant bits (or characters) lost. This truncation can occur without warning, and can cause the run-time system to pass incorrect information back to the program.

If the variable is a pointer, it must be associated with a definable target. The shape of the target and expression must conform and their type and kind parameters must match.

The following sections discuss numeric, logical, character, derived-type, and array intrinsic assignment.

**Numeric Assignment Statements**

For numeric assignment statements, the variable and expression must be numeric type.

The expression must yield a value that conforms to the range requirements of the variable. For example, a real expression that produces a value greater than 32767 is invalid if the entity on the left of the equal sign is an INTEGER(2) variable.

Significance can be lost if an INTEGER(4) value, which can exactly represent values of approximately the range -2*10**9 to +2*10**9, is converted to REAL(4) (including the real part of a complex constant), which is accurate to only about seven digits.

If the variable has the same data type as that of the expression on the right, the statement assigns the value directly. If the data types are different, the value of the expression is converted to the data type of the variable before it is assigned.

The following table summarizes the data conversion rules for numeric assignment statements.

**Table 570: Conversion Rules for Numeric Assignment Statements**

- AIMAG

Logical Assignment Statements

For logical assignment statements, the variable must be of logical type and the expression can be of logical or numeric type.

If necessary, the expression is converted to the same type and kind as the variable.

Examples

The following examples demonstrate valid logical assignment statements:

```
PAGEND = .FALSE.
PRNTOK = LINE .LE. 132 .AND. .NOT. PAGEND
ABIG = A.GT.B .AND. A.GT.C .AND. A.GT.D
LOGICAL_VAR = 123 ! Moves binary value of 123 to LOGICAL_VAR
```

Character Assignment Statements

For character assignment statements, the variable and expression must be of character type and have the same kind parameter.

The variable and expression can have different lengths. If the length of the expression is greater than the length of the variable, the character expression is truncated on the right. If the length of the expression is less than the length of the variable, the character expression is filled on the right with blank characters.
If you assign a value to a character substring, you do not affect character positions in any part of the character scalar variable not included in the substring. If a character position outside of the substring has a value previously assigned, it remains unchanged. If the character position is undefined, it remains undefined.

**Examples**

**Table 573: Valid Character Assignment Statements. (All variables are of type character.)**

```plaintext
FILE = 'PROG2'

REVOL(1) = 'MAR'/'CIA'

LOCA(3:8) = 'PLANT5'

TEXT(I,J+1)(2:N-1) = NAME/ /X
```

**Table 574: Invalid Character Assignment Statements**

```plaintext
'ABC' = CHAR

CHARS = 25

STRING=5HBEGIN
```

**Derived-Type Assignment Statements**

In derived-type assignment statements, the variable and expression must be of the same derived type. There must be no accessible interface block with defined assignment for objects of this derived type.

The derived-type assignment is performed as if each component of the expression is assigned to the corresponding component of the variable. Pointer assignment is performed for pointer components, and intrinsic assignment is performed for nonpointer components.
Examples
The following example shows derived-type assignment:

```fortran
TYPE DATE
   LOGICAL(1) DAY, MONTH
   INTEGER(2) YEAR
END TYPE DATE

TYPE(DATE) TODAY, THIS_WEEK(7)
TYPE APPOINTMENT
...
   TYPE(DATE) APP_DATE
END TYPE

TYPE(APPOINTMENT) MEETING
DO I = 1,7
   CALL GET_DATE(TODAY)
   THIS_WEEK(I) = TODAY
END DO
MEETING%APP_DATE = TODAY
```

See Also
- Intrinsic Assignments
- Derived types
- Pointer assignments

Array Assignment Statements
Array assignment is permitted when the array expression on the right has the same shape as the array variable on the left, or the expression on the right is a scalar.

If the expression is a scalar, and the variable is an array, the scalar value is assigned to every element of the array.

If the expression is an array, the variable must also be an array. The array element values of the expression are assigned (element by element) to corresponding elements of the array variable.
A many-one array section is a vector-valued subscript that has two or more elements with
the same value. In intrinsic assignment, the variable cannot be a many-one array section
because the result of the assignment is undefined.

Examples
In the following example, X and Y are arrays of the same shape:

\[ X = Y \]

The corresponding elements of Y are assigned to those of X element by element; the first element
of Y is assigned to the first element of X, and so forth. The processor can perform the
element-by-element assignment in any order.

The following example shows a scalar assigned to an array:

\[ B(C+1:N, C) = 0 \]

This sets the elements \( B(C+1,C), B(C+2,C),...B(N,C) \) to zero.

The following example causes the values of the elements of array A to be reversed:

\[ \text{REAL A(20)} \]

\[ \text{...} \]

\[ A(1:20) = A(20:1:-1) \]

- Arrays
- Array constructors
- WHERE
- FORALL

Defined Assignments

Defined assignment specifies an assignment operation. It is defined by a subroutine subprogram
containing a generic interface block with the specifier ASSIGNMENT(=). The subroutine is
specified by a SUBROUTINE or ENTRY statement that has two nonoptional dummy arguments.

Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE
statement.

The dummy arguments represent the variable and expression, in that order. The rank (and
shape, if either or both are arrays), type, and kind parameters of the variable and expression
in the assignment statement must match those of the corresponding dummy arguments.
The dummy arguments must not both be numeric, or of type logical or character with the same kind parameter.

If the variable in an elemental assignment is an array, the defined assignment is performed element-by-element, in any order, on corresponding elements of the variable and expression. If the expression is scalar, it is treated as if it were an array of the same shape as the variable with every element of the array equal to the scalar value of the expression.

**See Also**

- Assignment Statements
- Subroutines
- Derived data types
- Defining Generic Assignment
- Numeric Expressions
- Character Expressions

**Pointer Assignments**

In ordinary assignment involving pointers, the pointer is an alias for its target. In pointer assignment, the pointer is associated with a target. If the target is undefined or disassociated, the pointer acquires the same status as the target. The pointer assignment statement has the following form:

```
pointer-object => target
```

- **pointer-object**
  - Is a variable name or structure component declared with the POINTER attribute.

- **target**
  - Is a variable or expression. Its type and kind parameters, and rank must be the same as `pointer-object`. It cannot be an array section with a vector subscript.

**Description**

If the target is a variable, it must have the POINTER or TARGET attribute, or be a subobject whose parent object has the TARGET attribute.

If the target is an expression, the result must be a pointer.

If the target is not a pointer (it has the TARGET attribute), the pointer object is associated with the target.

If the target is a pointer (it has the POINTER attribute), its status determines the status of the pointer object, as follows:
• If the pointer is associated, the pointer object is associated with the same object as the target
• If the pointer is disassociated, the pointer object becomes disassociated
• If the pointer is undefined, the pointer object becomes undefined

A pointer must not be referenced or defined unless it is associated with a target that can be referenced or defined.

When pointer assignment occurs, any previous association between the pointer object and a target is terminated.

Pointers can also be assigned for a pointer structure component by execution of a derived-type intrinsic assignment statement or a defined assignment statement.

Pointers can also become associated by using the ALLOCATE statement to allocate the pointer.

Pointers can become disassociated by deallocation, nullification of the pointer (using the DEALLOCATE or NULLIFY statements), or by reference to the NULL intrinsic function.

**Examples**

The following are examples of pointer assignments:

```fortran
HOUR => MINUTES(1:60)  ! target is an array
M_YEAR => MY_CAR%YEAR  ! target is a structure component
NEW_ROW%RIGHT => CURRENT_ROW  ! pointer object is a structure component
PTR => M  ! target is a variable
POINTER_C => NULL ()  ! reference to NULL intrinsic
```

The following example shows a target as a pointer:

```fortran
INTEGER, POINTER :: P, N
INTEGER, TARGET :: M
INTEGER S
M = 14
N => M  ! N is associated with M
P => N  ! P is associated with M through N
S = P + 5
```

The value assigned to S is 19 (14 + 5).
You can use the intrinsic function `ASSOCIATED` to find out if a pointer is associated with a target or if two pointers are associated with the same target. For example:

```fortran
REAL C (:), D(:,), E(5)
POINTER C, D
TARGET E
LOGICAL STATUS
! Pointer assignment.
C => E
! Pointer assignment.
D => E
! Returns TRUE; C is associated.
STATUS = ASSOCIATED (C)
! Returns TRUE; C is associated with E.
STATUS = ASSOCIATED (C, E)
! Returns TRUE; C and D are associated with the
! same target.
STATUS = ASSOCIATED (C, D)
```

FORALL Statement and Construct Overview

The FORALL statement and construct is a generalization of the Fortran 95/90 masked array assignment. It allows more general array shapes to be assigned, especially in construct form. For more information, see FORALL.

See Also
- Assignment Statements
- WHERE
A specification statement is a nonexecutable statement that declares the attributes of data objects. In Fortran 95/90, many of the attributes that can be defined in specification statements can also be optionally specified in type declaration statements.

The following are specification statements:

- **Type declaration statement**
  Explicitly specifies the properties (for example: data type, rank, and extent) of data objects.

- **ALLOCATABLE attribute and statement**
  Specifies a list of array names that are allocatable (have a deferred-shape).

- **ASYNCHRONOUS attribute and statement**
  Specifies that a variable can be used for asynchronous input and output.

- **AUTOMATIC and STATIC attributes and statements**
  Control the storage allocation of variables in subprograms.

- **BIND attribute and statement**
  Specifies that an object is interoperable with C and has external linkage.

- **COMMON statement**
  Defines one or more contiguous areas, or blocks, of physical storage (called common blocks).

- **DATA statement**
  Assigns initial values to variables before program execution.

- **DIMENSION attribute and statement**
  Specifies that an object is an array, and defines the shape of the array.

- **EQUIVALENCE statement**
  Specifies that a storage area is shared by two or more objects in a program unit.

- **EXTERNAL attribute and statement**
  Allows external (user-supplied) procedures to be used as arguments to other subprograms.

- **IMPLICIT statement**
  Overrides the implicit data type of names.

- **INTENT attribute and statement**
  Specifies the intended use of a dummy argument.
• **INTRINSIC attribute and statement**
  Allows intrinsic procedures to be used as arguments to subprograms.

• **NAMELIST statement**
  Associates a name with a list of variables. This group name can be referenced in some input/output operations.

• **OPTIONAL attribute and statement**
  Allows a procedure reference to omit arguments.

• **PARAMETER attribute and statement**
  Defines a named constant.

• **POINTER attribute and statement**
  Specifies that an object is a pointer.

• **PRIVATE and PUBLIC and attributes and statements**
  Declare the accessibility of entities in a module.

• **PROTECTED attribute and statement**
  Specifies limitations on the use of module entities.

• **SAVE attribute and statement**
  Causes the definition and status of objects to be retained after the subprogram in which they are declared completes execution.

• **TARGET attribute and statement**
  Specifies a pointer target.

• **VALUE attribute and statement**
  Specifies a type of argument association for a dummy argument.

• **VOLATILE attribute and statement**
  Prevents optimizations from being performed on specified objects.

**Type Declaration Statements**

A type declaration statement explicitly specifies the properties of data objects or functions. For more information, see *Type Declarations*.

**See Also**

• **Specification Statements**
Declaration Statements for Noncharacter Types

The following table shows the data types that can appear in noncharacter type declaration statements.

<table>
<thead>
<tr>
<th>Noncharacter Data Types</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>BYTE</strong>&lt;sup&gt;1&lt;/sup&gt;</td>
</tr>
<tr>
<td><strong>LOGICAL</strong>&lt;sup&gt;2&lt;/sup&gt;</td>
</tr>
<tr>
<td>LOGICAL([KIND=]1) (or LOGICAL*1)</td>
</tr>
<tr>
<td>LOGICAL([KIND=]2) (or LOGICAL*2)</td>
</tr>
<tr>
<td>LOGICAL([KIND=]4) (or LOGICAL*4)</td>
</tr>
<tr>
<td>LOGICAL([KIND=]8) (or LOGICAL*8)</td>
</tr>
<tr>
<td><strong>INTEGER</strong>&lt;sup&gt;3&lt;/sup&gt;</td>
</tr>
<tr>
<td>INTEGER([KIND=]1) (or INTEGER*1)</td>
</tr>
<tr>
<td>INTEGER([KIND=]2) (or INTEGER*2)</td>
</tr>
<tr>
<td>INTEGER([KIND=]4) (or INTEGER*4)</td>
</tr>
</tbody>
</table>
Noncharacter Data Types

INTEGER([KIND=]8) (or INTEGER*8)

REAL\(^4\)

REAL([KIND=]4) (or REAL*4)

DOUBLE PRECISION (REAL([KIND=]8) or REAL*8)

REAL([KIND=]16) (or REAL*16)

COMPLEX\(^5\)

COMPLEX([KIND=]4) (or COMPLEX*8)

DOUBLE COMPLEX (COMPLEX([KIND=]8) or COMPLEX*16)

COMPLEX([KIND=]16) (or COMPLEX*32)

\(^1\) Same as INTEGER(1).

\(^2\) This is treated as default logical.

\(^3\) This is treated as default integer.

\(^4\) This is treated as default real.

\(^5\) This is treated as default complex.

In noncharacter type declaration statements, you can optionally specify the name of the data object or function as \(v*n\), where \(n\) is the length (in bytes) of \(v\). The length specified overrides the length implied by the data type.

The value for \(n\) must be a valid length for the type of \(v\). The type specifiers BYTE, DOUBLE PRECISION, and DOUBLE COMPLEX have one valid length, so the \(n\) specifier is invalid for them.

For an array specification, the \(n\) must be placed immediately following the array name; for example, in an INTEGER declaration statement, IVEC*2(10) is an INTEGER(2) array of 10 elements.

Note that certain compiler options can affect the defaults for numeric and logical data types.
Examples
In a noncharacter type declaration statement, a subsequent kind parameter overrides any initial kind parameter. For example, consider the following statements:

```fortran
INTEGER(KIND=2) I, J, K, M12*4, Q, IVEC*4(10)
REAL(KIND=8) WX1, WXZ, WX3*4, WX5, WX6*4
REAL(KIND=8) PI/3.14159E0/, E/2.72E0/, QARRAY(10)/5*0.0,5*1.0/
```

In the first statement, `M12*4` and `IVEC*4` override the `KIND=2` specification. In the second statement, `WX3*4` and `WX6*4` override the `KIND=8` specification. In the third statement, `QARRAY` is initialized with implicit conversion of the REAL(4) constants to a REAL(8) data type.

Declaration Statements for Character Types
A CHARACTER type specifier can be immediately followed by the length of the character object or function. It takes one of the following forms:

**Keyword Forms**
CHARACTER *((LEN=len))
CHARACTER *((LEN=len [, [KIND=n]]))
CHARACTER *((KIND=n [, LEN=len]])

**Nonkeyword Form**
CHARACTER*len[,

`len` is one of the following:
- In keyword forms
  - The `len` is a specification expression or an asterisk (*). If no length is specified, the default length is 1.
  - If the length evaluates to a negative value, the length of the character entity is zero.
- In nonkeyword form
The len is a specification expression or an asterisk enclosed in parentheses, or a scalar integer literal constant (with no kind parameter). The comma is permitted only if no double colon (::) appears in the type declaration statement.

This form can also (optionally) be specified following the name of the data object or function (v*len). In this case, the length specified overrides any length following the CHARACTER type specifier.

The largest valid value for len in both forms is 2**31-1 on IA-32 architecture; 2**63-1 on Intel® 64 architecture and IA-64 architecture. Negative values are treated as zero.

n Is a scalar integer initialization expression specifying a valid kind parameter. Currently the only kind available is 1.

Description

An automatic object can appear in a character declaration. The object cannot be a dummy argument, and its length must be declared with a specification expression that is not a constant expression.

The length specified for a character-valued statement function or statement function dummy argument of type character must be an integer constant expression.

When an asterisk length specification *(*) is used for a function name or dummy argument, it assumes the length of the corresponding function reference or actual argument. Similarly, when an asterisk length specification is used for a named constant, the name assumes the length of the actual constant it represents. For example, STRING assumes a 9-byte length in the following statements:

```
CHARACTER*(*) STRING
PARAMETER (STRING = 'VALUE IS:')
```

A function name must not be declared with a * length, if the function is an internal or module function, or if it is array-valued, pointer-valued, recursive, or pure.

The form CHARACTER*(*) is an obsolescent feature in Fortran 95.

Examples

In the following example, the character string last_name is given a length of 20:

```
CHARACTER (LEN=20) last_name
```
In the following example, stri is given a length of 12, while the other two variables retain a length of 8.

```
CHARACTER *8 strg, strh, stri*12
```

In the following example, as a dummy argument strh is given the length of an assigned string when it is assigned, while the other two variables retain a length of 8:

```
CHARACTER *8 strg, strh(*), stri
```

The following examples show ways to specify strings of known length:

```
CHARACTER*32 string

CHARACTER string*32
```

The following examples show ways to specify strings of unknown length:

```
CHARACTER string(*)

CHARACTER*(*) string
```

The following example declares an array NAMES containing 100 32-character elements, an array SOCSEC containing 100 9-character elements, and a variable NAMETY that is 10 characters long and has an initial value of 'ABCDEFGHIJ'.

```
CHARACTER*32 NAMES(100),SOCSEC(100)*9,NAMETY*10 /'ABCDEFGHIJ'/
```

The following example includes a CHARACTER statement declaring two 8-character variables, LAST and FIRST.

```
INTEGER, PARAMETER :: LENGTH=4

CHARACTER*(4+LENGTH) LAST, FIRST
```

The following example shows a CHARACTER statement declaring an array LETTER containing 26 one-character elements. It also declares a dummy argument BUBBLE that has a passed length defined by the calling program.

```
CHARACTER LETTER(26), BUBBLE*(*)
```

In the following example, NAME2 is an automatic object:

```
SUBROUTINE AUTO_NAME(NAME1)

    CHARACTER(LEN = *) NAME1

    CHARACTER(LEN = LEN(NAME1)) NAME2
```

Declaration Statements for Derived Types

The derived-type (TYPE) declaration statement specifies the properties of objects and functions of derived (user-defined) type.

The derived type must be defined before you can specify objects of that type in a TYPE type declaration statement.

An object of derived type must not have the PUBLIC attribute if its type is PRIVATE.

A structure constructor specifies values for derived-type objects.

Examples

The following are examples of derived-type declaration statements:

```
TYPE(EMPLOYEE) CONTRACT
...
TYPE(SETS), DIMENSION(:,,:), ALLOCATABLE :: SUBSET_1
```

The following example shows a public type with private components:

```
TYPE LIST_ITEMS
  PRIVATE
...
  TYPE(LIST_ITEMS), POINTER :: NEXT, PREVIOUS
END TYPE LIST_ITEMS
```

Declaration Statements for Arrays

An array declaration (or array declarator) declares the shape of an array. It takes the following form:

\[(a\text{-}spec)\]

\[a\text{-}spec\]

Is one of the following array specifications:

- Explicit-shape
- Assumed-shape
- Assumed-size
- Deferred-shape

The array specification can be appended to the name of the array when the array is declared.

Examples

The following examples show array declarations:

```fortran
SUBROUTINE SUB(N, C, D, Z)

REAL, DIMENSION(N, 15) :: IARRY ! An explicit-shape array
REAL C(:), D(0:) ! An assumed-shape array
REAL, POINTER :: B(:,:) ! A deferred-shape array pointer
REAL, ALLOCATABLE, DIMENSION(:) :: K ! A deferred-shape allocatable array
REAL :: Z(N,*) ! An assumed-size array
```

See Also

- Type Declaration Statements
- Explicit-Shape Specifications
- Assumed-Shape Specifications
- Assumed-Size Specifications
- Deferred-Shape Specifications
- Type Declarations

Explicit-Shape Specifications

An explicit-shape array is declared with explicit values for the bounds in each dimension of the array. An explicit-shape specification takes the following form:

\([dl:] du[, [dl:] du] \ldots\)
**dl**

Is a specification expression indicating the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type.

If the lower bound is not specified, it is assumed to be 1.

**du**

Is a specification expression indicating the upper bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type.

The bounds can be specified as constant or nonconstant expressions, as follows:

- If the bounds are constant expressions, the subscript range of the array in a dimension is the set of integer values between and including the lower and upper bounds. If the lower bound is greater than the upper bound, the range is empty, the extent in that dimension is zero, and the array has a size of zero.

- If the bounds are nonconstant expressions, the array must be declared in a procedure. The bounds can have different values each time the procedure is executed, since they are determined when the procedure is entered.

The bounds are not affected by any redefinition or undefinition of the variables in the specification expression that occurs while the procedure is executing.

The following explicit-shape arrays can specify nonconstant bounds:

- An **automatic array** (the array is a local variable)
- An **adjustable array** (the array is a dummy argument to a subprogram)

The following are examples of explicit-shape specifications:

```
INTEGER I(3:8, -2:5)  ! Rank-two array; range of dimension one is
one is                      ! 3 to 8, range of dimension two is -2
to 5
...

SUBROUTINE SUB(A, B, C)

INTEGER :: B, C

REAL, DIMENSION(B:C) :: A  ! Rank-one array; range is B to C
```
Consider the following:

```
INTEGER M(10, 10, 10)
INTEGER K(-3:6, 4:13, 0:9)
```

M and K are both explicit-shape arrays with a rank of 3, a size of 1000, and the same shape (10,10,10). Array M uses the default lower bound of 1 for each of its dimensions. So, when it is declared only the upper bound needs to be specified. Each of the dimensions of array K has a lower bound other than the default, and the lower bounds as well as the upper bounds are declared.

**Automatic Arrays**

An **automatic array** is an explicit-shape array that is a local variable. Automatic arrays are only allowed in function and subroutine subprograms, and are declared in the specification part of the subprogram. At least one bound of an automatic array must be a nonconstant specification expression. The bounds are determined when the subprogram is called.

The following example shows automatic arrays:

```fortran
SUBROUTINE SUB1 (A, B)
   INTEGER A, B, LOWER
   COMMON /BOUND/ LOWER
   ...
   INTEGER AUTO_ARRAY1(B)
   ...
   INTEGER AUTO_ARRAY2(LOWER:B)
   ...
   INTEGER AUTO_ARRAY3(20, B*A/2)
END SUBROUTINE
```

**Consider the following:**

```fortran
SUBROUTINE EXAMPLE (N, R1, R2)
   DIMENSION A (N, 5), B(10*N)
   ...
   N = IFIX(R1) + IFIX(R2)
```
When the subroutine is called, the arrays A and B are dimensioned on entry into the subroutine with the value of the passed variable N. Later changes to the value of N have no effect on the dimensions of array A or B.

**Adjustable Arrays**

An *adjustable array* is an explicit-shape array that is a dummy argument to a subprogram. At least one bound of an adjustable array must be a nonconstant specification expression. The bounds are determined when the subprogram is called.

The array specification can contain integer variables that are either dummy arguments or variables in a common block.

When the subprogram is entered, each dummy argument specified in the bounds must be associated with an actual argument. If the specification includes a variable in a common block, the variable must have a defined value. The array specification is evaluated using the values of the actual arguments, as well as any constants or common block variables that appear in the specification.

The size of the adjustable array must be less than or equal to the size of the array that is its corresponding actual argument.

To avoid possible errors in subscript evaluation, make sure that the bounds expressions used to declare multidimensional adjustable arrays match the bounds as declared by the caller.

In the following example, the function computes the sum of the elements of a rank-two array. Notice how the dummy arguments M and N control the iteration:

```fortran
FUNCTION THE_SUM(A, M, N)
    DIMENSION A(M, N)
    SUMX = 0.0
    DO J = 1, N
        DO I = 1, M
            SUMX = SUMX + A(I, J)
        END DO
    END DO
    THE_SUM = SUMX
END FUNCTION
```
The following are examples of calls on THE_SUM:

\[
\text{DIMENSION } A1(10,35), A2(3,56) \\
\text{SUM1 = THE\_SUM(A1,10,35)} \\
\text{SUM2 = THE\_SUM(A2,3,56)}
\]

The following example shows how the array bounds determined when the procedure is entered do not change during execution:

\[
\text{DIMENSION ARRAY(9,5)} \\
L = 9 \\
M = 5 \\
\text{CALL SUB(ARRAY,L,M)} \\
\text{END}
\]

\[
\text{SUBROUTINE SUB(X,I,J)} \\
\qquad \text{DIMENSION X(-I/2:I/2,J)} \\
\qquad X(I/2,J) = 999 \\
\qquad J = 1 \\
\qquad I = 2 \\
\text{END}
\]

The assignments to I and J do not affect the declaration of adjustable array X as X(-4:4,5) on entry to subroutine SUB.

**See Also**
- Declaration Statements for Arrays
- Specification expressions

**Assumed-Shape Specifications**

An *assumed-shape array* is a dummy argument array that assumes the shape of its associated actual argument array. An assumed-shape specification takes the following form:

\[
([d_1]:[, [d_2]:] ...) \\
\]

`d_1` is a specification expression indicating the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. If the lower bound is not specified, it is assumed to be 1.

The rank of the array is the number of colons (:) specified.
The value of the upper bound is the extent of the corresponding dimension of the associated actual argument array + lower-bound - 1.

Examples

The following is an example of an assumed-shape specification:

```fortran
INTERFACE
  SUBROUTINE SUB(M)
    INTEGER M(:, 1:, 5:)
  END SUBROUTINE
END INTERFACE

INTEGER L(20, 5:25, 10)
CALL SUB(L)

SUBROUTINE SUB(M)
  INTEGER M(:, 1:, 5:)
END SUBROUTINE
```

Array M has the same extents as array L, but array M has bounds (1:20, 1:21, 5:14).

Note that an explicit interface is required when calling a routine that expects an assumed-shape or pointer array.

Consider the following:

```fortran
SUBROUTINE ASSUMED(A)
  REAL A(:, :, :)
END SUBROUTINE
```

Array A has rank 3, indicated by the three colons (:) separated by commas (,). However, the extent of each dimension is unspecified. When the subroutine is called, A takes its shape from the array passed to it. For example, consider the following:

```fortran
REAL X (4, 7, 9)
... 
CALL ASSUMED(X)
```

This gives A the dimensions (4, 7, 9). The actual array and the assumed-shape array must have the same rank.
Consider the following:

```fortran
SUBROUTINE ASSUMED(A)
    REAL A(3:, 0:, -2:)
...
```

If the subroutine is called with the same actual array `X(4, 7, 9)`, as in the previous example, the lower and upper bounds of `A` would be:

`A(3:6, 0:6, -2:6)`

**Assumed-Size Specifications**

An assumed-size array is a dummy argument array that assumes the size (only) of its associated actual argument array; the rank and extents can differ for the actual and dummy arrays. An assumed-size specification takes the following form:

```
([expli-shape-spec], [expli-shape-spec], ... [dl: ] *)
```

- `expli-shape-spec` is an explicit-shape specification.
- `dl` is the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type.
- The upper bound of the last dimension.

The rank of the array is the number of explicit-shape specifications plus 1.

The size of the array is assumed from the actual argument associated with the assumed-size dummy array as follows:

- If the actual argument is an array of type other than default character, the size of the dummy array is the size of the actual array.
- If the actual argument is an array element of type other than default character, the size of the dummy array is `a + 1 - s`, where `s` is the subscript order value and `a` is the size of the actual array.
- If the actual argument is a default character array, array element, or array element substring, and it begins at character storage unit `b` of an array with `n` character storage units, the size of the dummy array is as follows:
  \[
  \text{MAX}(\text{INT}((n + 1 - b)/y), 0)
  \]
  where `y` is the length of an element of the dummy array.

An assumed-size array can only be used as a whole array reference in the following cases:

- When it is an actual argument in a procedure reference that does not require the shape
In the intrinsic function \texttt{LBOUND}

Because the actual size of an assumed-size array is unknown, an assumed-size array cannot be used as any of the following in an I/O statement:

- An array name in the I/O list
- A unit identifier for an internal file
- A run-time format specifier

\textbf{Examples}

The following is an example of an assumed-size specification:

\begin{verbatim}
SUBROUTINE SUB(A, N)
  REAL A, N
  DIMENSION A(1:N, *)
...
\end{verbatim}

The following example shows that you can specify lower bounds for any of the dimensions of an assumed-size array, including the last:

\begin{verbatim}
SUBROUTINE ASSUME(A)
  REAL A(-4:-2, 4:6, 3:*)
\end{verbatim}

\textbf{See Also}

- Declaration Statements for Arrays
- Array Elements

\textbf{Deferred-Shape Specifications}

A \textit{deferred-shape} array is an array pointer or an allocatable array.

The array specification contains a colon (:) for each dimension of the array. No bounds are specified. The bounds (and shape) of allocatable arrays and array pointers are determined when space is allocated for the array during program execution.

An \textit{array pointer} is an array declared with the \texttt{POINTER} attribute. Its bounds and shape are determined when it is associated with a target by pointer assignment, or when the pointer is allocated by execution of an \texttt{ALLOCATE} statement.

In pointer assignment, the lower bound of each dimension of the array pointer is the result of the \texttt{LBOUND} intrinsic function applied to the corresponding dimension of the target. The upper bound of each dimension is the result of the \texttt{UBOUND} intrinsic function applied to the corresponding dimension of the target.
A pointer dummy argument can be associated only with a pointer actual argument. An actual argument that is a pointer can be associated with a nonpointer dummy argument.

A function result can be declared to have the pointer attribute.

An allocatable array is declared with the ALLOCATABLE attribute. Its bounds and shape are determined when the array is allocated by execution of an ALLOCATE statement.

Examples

The following are examples of deferred-shape specifications:

```fortran
REAL, ALLOCATABLE :: A(:, :) ! Allocatable array
REAL, POINTER :: C(:,), D (:,:, :) ! Array pointers
```

If a deferred-shape array is declared in a DIMENSION or TARGET statement, it must be given the ALLOCATABLE or POINTER attribute in another statement. For example:

```fortran
DIMENSION P(:, :, :)
POINTER P
TARGET B(:,:)
ALLOCATABLE B
```

If the deferred-shape array is an array of pointers, its size, shape, and bounds are set in an ALLOCATE statement or in the pointer assignment statement when the pointer is associated with an allocated target. A pointer and its target must have the same rank.

For example:

```fortran
REAL, POINTER :: A(:, :), B(:,), C(:, :)
INTEGER, ALLOCATABLE :: I(:)
REAL, ALLOCATABLE, TARGET :: D(:, :), E(:)
```

```fortran
... ALLOCATE (A(2, 3), I(5), D(SIZE(I), 12), E(98) )
C => D ! Pointer assignment statement
B => E(25:56) ! Pointer assignment to a section of a target
```

ALLOCATABLE Attribute and Statement Overview

The ALLOCATABLE attribute specifies that an array is an allocatable array with a deferred shape. The shape of an allocatable array is determined when an ALLOCATE statement is executed, dynamically allocating space for the array. For more information, see ALLOCATABLE.

ASYNCHRONOUS Attribute and Statement Overview

The ASYNCHRONOUS attribute specifies that a variable can be used for asynchronous input and output. For more information, see ASYNCHRONOUS.

AUTOMATIC and STATIC Attributes and Statements Overview

The AUTOMATIC and STATIC attributes control the storage allocation of variables in subprograms. For more information, see AUTOMATIC and STATIC.

BIND Attribute and Statement Overview

The BIND statement specifies that an object is interoperable with C and has external linkage. For more information, see BIND.

COMMON Statement Overview

A COMMON statement defines one or more contiguous areas, or blocks, of physical storage (called common blocks) that can be accessed by any of the scoping units in an executable program. COMMON statements also define the order in which variables and arrays are stored in each common block, which can prevent misaligned data items. For more information, see COMMON.
DATA Statement Overview

The DATA statement assigns initial values to variables before program execution. For more information, see DATA.

DIMENSION Attribute and Statement Overview

The DIMENSION attribute specifies that an object is an array, and defines the shape of the array. For more information, see DIMENSION.

EQUIVALENCE Statement Overview

The EQUIVALENCE statement specifies that a storage area is shared by two or more objects in a program unit. This causes total or partial storage association of the objects that share the storage area. For more information, see EQUIVALENCE.

See Also

• Specification Statements
• Making Arrays Equivalent
• Making Substrings Equivalent
• EQUIVALENCE and COMMON Interaction

Making Arrays Equivalent

When you make an element of one array equivalent to an element of another array, the EQUIVALENCE statement also sets equivalences between the other elements of the two arrays. Thus, if the first elements of two equal-sized arrays are made equivalent, both arrays share the same storage. If the third element of a 7-element array is made equivalent to the first element of another array, the last five elements of the first array overlap the first five elements of the second array.

Two or more elements of the same array should not be associated with each other in one or more EQUIVALENCE statements. For example, you cannot use an EQUIVALENCE statement to associate the first element of one array with the first element of another array, and then attempt to associate the fourth element of the first array with the seventh element of the other array.
Consider the following example:

```
DIMENSION TABLE (2,2), TRIPLE (2,2,2)
EQUIVALENCE(TABLE(2,2), TRIPLE(1,2,2))
```

These statements cause the entire array TABLE to share part of the storage allocated to TRIPLE. The following table shows how these statements align the arrays:

<table>
<thead>
<tr>
<th>Array TRIPLE</th>
<th>Array TABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRIPLE(1,1,1)</td>
<td>1</td>
</tr>
<tr>
<td>TRIPLE(2,1,1)</td>
<td>2</td>
</tr>
<tr>
<td>TRIPLE(1,2,1)</td>
<td>3</td>
</tr>
<tr>
<td>TRIPLE(2,2,1)</td>
<td>4</td>
</tr>
<tr>
<td>TRIPLE(1,1,2)</td>
<td>5</td>
</tr>
<tr>
<td>TRIPLE(2,1,2)</td>
<td>6</td>
</tr>
<tr>
<td>TRIPLE(1,2,2)</td>
<td>7</td>
</tr>
<tr>
<td>TRIPLE(2,2,2)</td>
<td>8</td>
</tr>
</tbody>
</table>

Each of the following statements also aligns the two arrays as shown in the above table:

```
EQUIVALENCE(TABLE, TRIPLE(2,2,1))
EQUIVALENCE(TRIPLE(1,1,2), TABLE(2,1))
```

You can also make arrays equivalent with nonunity lower bounds. For example, an array defined as A(2:3,4) is a sequence of eight values. A reference to A(2,2) refers to the third element in the sequence. To make array A(2:3,4) share storage with array B(2:4,4), you can use the following statement:

```
EQUIVALENCE(A(3,4), B(2,4))
```

The entire array A shares part of the storage allocated to array B. The following table shows how these statements align the arrays. The arrays can also be aligned by the following statements:

```
EQUIVALENCE(A, B(4,1))
EQUIVALENCE(B(3,2), A(2,2))
```
Table 577: Equivalence of Arrays with Nonunity Lower Bounds

Only in the EQUIVALENCE statement can you identify an array element with a single subscript (the linear element number), even though the array was defined as multidimensional. For example, the following statements align the two arrays as shown in the above table:

```fortran
DIMENSION B(2:4,1:4), A(2:3,1:4)
EQUIVALENCE(B(6), A(4))
```

Making Substrings Equivalent

When you make one character substring equivalent to another character substring, the EQUIVALENCE statement also sets associations between the other corresponding characters in the character entities; for example:

```fortran
CHARACTER NAME*16, ID*9
EQUIVALENCE(NAME(10:13), ID(2:5))
```
These statements cause character variables NAME and ID to share space (see the following figure). The arrays can also be aligned by the following statement:

\[ \text{EQUIVALENCE}(\text{NAME}(9:9), \text{ID}(1:1)) \]

**Figure 28: Equivalence of Substrings**

ZK-0618-GE
If the character substring references are array elements, the EQUIVALENCE statement sets associations between the other corresponding characters in the complete arrays.
Character elements of arrays can overlap at any character position. For example, the following statements cause character arrays FIELDS and STAR to share storage (see the following figure).

```fortran
CHARACTER FIELDS(100)*4, STAR(5)*5

EQUIVALENCE(FIELDS(1)(2:4), STAR(2)(3:5))
```
Figure 29: Equivalence of Character Arrays
The EQUIVALENCE statement cannot assign the same storage location to two or more substrings that start at different character positions in the same character variable or character array. The EQUIVALENCE statement also cannot assign memory locations in a way that is inconsistent with the normal linear storage of character variables and arrays.

**EQUIVALENCE and COMMON Interaction**

A common block can extend beyond its original boundaries if variables or arrays are associated with entities stored in the common block. However, a common block can only extend beyond its last element; the extended portion cannot precede the first element in the block.
Examples

The following two figures demonstrate valid and invalid extensions of the common block, respectively.

**Figure 30: A Valid Extension of a Common Block**

<table>
<thead>
<tr>
<th>Valid</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIMENSION A(4), B(6)</td>
</tr>
<tr>

<th>A(2)</th>
<th>A(3)</th>
<th>A(4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>B(1)</td>
<td>B(2)</td>
<td>B(3)</td>
<td>B(4)</td>
</tr>
</tbody>
</table>

Extended Portion  
Existing Common  
Extended Portion

ZK-1945-GE

The second example is invalid because the extended portion, B(1), precedes the first element of the common block.
The following example shows a valid EQUIVALENCE statement and an invalid EQUIVALENCE statement in the context of a common block.

```fortran
COMMON A, B, C
DIMENSION D(3)
EQUIVALENCE(B, D(1)) ! Valid, because common block is extended from the end.

COMMON A, B, C
DIMENSION D(3)
EQUIVALENCE(B, D(3)) ! Invalid, because D(1) would extend common block to precede A's location.
```

**EXTERNAL Attribute and Statement Overview**

The EXTERNAL attribute allows an external or dummy procedure to be used as an actual argument. For more information, see [EXTERNAL](#).

**IMPLICIT Statement Overview**

The IMPLICIT statement overrides the default implicit typing rules for names. For more information, see [IMPLICIT](#).

**INTENT Attribute and Statement Overview**

The INTENT attribute specifies the intended use of one or more dummy arguments. For more information, see [INTENT](#).

**INTRINSIC Attribute and Statement Overview**

The INTRINSIC attribute allows the specific name of an intrinsic procedure to be used as an actual argument. Certain specific function names cannot be used; these are indicated in table [Intrinsic Functions Not Allowed as Actual Arguments](#).

For more information, see [INTRINSIC](#).
NAMELIST Statement Overview

The NAMELIST statement associates a name with a list of variables. This group name can be referenced in some input/output operations. For more information, see NAMELIST.

OPTIONAL Attribute and Statement Overview

The OPTIONAL attribute permits dummy arguments to be omitted in a procedure reference. For more information, see OPTIONAL.

PARAMETER Attribute and Statement Overview

The PARAMETER attribute defines a named constant. For more information, see PARAMETER.

POINTER Attribute and Statement Overview

The POINTER attribute specifies that an object is a pointer (a dynamic variable). For more information, see POINTER.

PROTECTED Attribute and Statement Overview

The PROTECTED attribute specifies limitations on the use of module entities. For more information, see PROTECTED.

PUBLIC and PRIVATE Attributes and Statements Overview

The PRIVATE and PUBLIC attributes specify the accessibility of entities in a module. (These attributes are also called accessibility attributes.) For more information, see PUBLIC and PRIVATE.

SAVE Attribute and Statement Overview

The SAVE attribute causes the values and definition of objects to be retained after execution of a RETURN or END statement in a subprogram. For more information, see SAVE.
TARGET Attribute and Statement Overview

The TARGET attribute specifies that an object can become the target of a pointer. For more information, see TARGET.

IMPORT Statement Overview

The IMPORT statement makes host entities accessible in the interface body of an interface block. For more information, see IMPORT.

VOLATILE Attribute and Statement Overview

The VOLATILE attribute specifies that the value of an object is entirely unpredictable, based on information local to the current program unit. For more information, see VOLATILE.
Dynamic Allocation

Data objects can be static or dynamic. If a data object is static, a fixed amount of memory storage is created for it at compile time and is not freed until the program exits. If a data object is dynamic, memory storage for the object can be created (allocated), altered, or freed (deallocated) as a program executes.

In Fortran 95/90, pointers, allocatable arrays, and automatic arrays are dynamic data objects.

No storage space is created for a pointer until it is allocated with an ALLOCATE statement or until it is assigned to a allocated target. A pointer can be dynamically disassociated from a target by using a NULLIFY statement.

An ALLOCATE statement can also be used to create storage for an allocatable array. A DEALLOCATE statement is used to free the storage space reserved in a previous ALLOCATE statement.

Automatic arrays differ from allocatable arrays in that they are automatically allocated and deallocated whenever you enter or leave a procedure, respectively.

NOTE. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. Dynamic allocations that are too large or otherwise attempt to use the protected memory of other applications result in General Protection Fault errors. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Control Panel or redefine the swap file size.

Some programming techniques can help minimize memory requirements, such as using one large array instead of two or more individual arrays. Allocated arrays that are no longer needed should be deallocated.

ALLOCATE Statement Overview

The ALLOCATE statement dynamically creates storage for allocatable arrays and pointer targets. The storage space allocated is uninitialized. For more information, see ALLOCATE.

See Also
- Dynamic Allocation
- Allocation of Allocatable Arrays
- Allocation of Pointer Targets
- Allocation of Allocatable Arrays
- Allocation of Pointer Targets
**Allocation of Allocatable Arrays**

The bounds (and shape) of an allocatable array are determined when it is allocated. Subsequent redefinition or undefinition of any entities in the bound expressions does not affect the array specification.

If the lower bound is greater than the upper bound, that dimension has an extent of zero, and the array has a size of zero. If the lower bound is omitted, it is assumed to be 1.

When an array is allocated, it is definable. If you try to allocate a currently allocated allocatable array, an error occurs.

The intrinsic function ALLOCATED can be used to determine whether an allocatable array is currently allocated; for example:

```fortran
REAL, ALLOCATABLE :: E(:,:)
...
IF (.NOT. ALLOCATED(E)) ALLOCATE(E(2:4,?))
```

**Allocation Status**

During program execution, the allocation status of an allocatable array is one of the following:

- **Not currently allocated**
  The array was never allocated or the last operation on it was a deallocation. Such an array must not be referenced or defined.

- **Currently allocated**
  The array was allocated by an ALLOCATE statement. Such an array can be referenced, defined, or deallocated.

If an allocatable array has the SAVE attribute, it has an initial status of "not currently allocated". If the array is then allocated, its status changes to "currently allocated". It keeps that status until the array is deallocated.

If an allocatable array does not have the SAVE attribute, it has the status of "not currently allocated" at the beginning of each invocation of the procedure. If the array's status changes to "currently allocated", it is deallocated if the procedure is terminated by execution of a RETURN or END statement.
Example: Allocating Virtual Memory

The following example shows a program that performs virtual memory allocation. This program uses Fortran 95/90 standard-conforming statements instead of calling an operating system memory allocation routine.

! Program accepts an integer and displays square root values

INTEGER(4) :: N

READ (5,*) N  ! Reads an integer value

CALL MAT(N)

END

! Subroutine MAT uses the typed integer value to display the square root values of numbers from 1 to N (the number read)

SUBROUTINE MAT(N)

REAL(4), ALLOCATABLE :: SQR(:,)  ! Declares SQR as a one-dimensional allocatable array

ALLOCATE (SQR(N))  ! Allocates array SQR

DO J=1,N

  SQR(J) = SQRT(FLOAT(J))  ! FLOATJ converts integer to REAL

ENDDO

WRITE (6,*) SQR  ! Displays calculated values

DEALLOCATE (SQR)  ! Deallocates array SQR

END SUBROUTINE MAT

Allocation of Pointer Targets

When a pointer is allocated, the pointer is associated with a target and can be used to reference or define the target. (The target can be an array or a scalar, depending on how the pointer was declared.)
Other pointers can become associated with the pointer target (or part of the pointer target) by pointer assignment.

In contrast to allocatable arrays, a pointer can be allocated a new target even if it is currently associated with a target. The previous association is broken and the pointer is then associated with the new target.

If the previous target was created by allocation, it becomes inaccessible unless it can still be referred to by other pointers that are currently associated with it.

The intrinsic function ASSOCIATED can be used to determine whether a pointer is currently associated with a target. (The association status of the pointer must be defined.) For example:

```fortran
REAL, TARGET :: TAR(0:50)
REAL, POINTER :: PTR(:)
PTR => TAR
...
IF (ASSOCIATED(PTR,TAR))...
```

See Also
- ALLOCATE Statement Overview
- POINTER statement and attribute
- Pointer assignments
- ASSOCIATED intrinsic function

DEALLOCATE Statement Overview

The DEALLOCATE statement frees the storage allocated for allocatable arrays and pointer targets (and causes the pointers to become disassociated). For more information, see DEALLOCATE.

See Also
- Dynamic Allocation
- Deallocation of Allocatable Arrays
- Deallocation of Pointer Targets
- Deallocation of Allocatable Arrays
- Deallocation of Pointer Targets

Deallocation of Allocatable Arrays

If the DEALLOCATE statement specifies an array that is not currently allocated, an error occurs.
If an allocatable array with the TARGET attribute is deallocated, the association status of any pointer associated with it becomes undefined.

If a RETURN or END statement terminates a procedure, an allocatable array has one of the following allocation statuses:

- It keeps its previous allocation and association status if the following is true:
  - It has the SAVE attribute.
  - It is in the scoping unit of a module that is accessed by another scoping unit which is currently executing.
  - It is accessible by host association.

- It remains allocated if it is accessed by use association.

- Otherwise, its allocation status is deallocated.

The intrinsic function `ALLOCATED` can be used to determine whether an allocatable array is currently allocated; for example:

```fortran
SUBROUTINE TEST
  REAL, ALLOCATABLE, SAVE :: F(:, :)
  REAL, ALLOCATABLE :: E(:, :, :)
  ...
  IF (.NOT. ALLOCATED(E)) ALLOCATE(E(2:4, 7, 14))
END SUBROUTINE TEST
```

Note that when subroutine TEST is exited, the allocation status of F is maintained because F has the SAVE attribute. Since E does not have the SAVE attribute, it is deallocated. On the next invocation of TEST, E will have the status of "not currently allocated".

**See Also**
- DEALLOCATE Statement Overview
- Host association
- TARGET statement and attribute
- RETURN statement
- END statement
- SAVE statement
Deallocation of Pointer Targets

A pointer must not be deallocated unless it has a defined association status. If the DEALLOCATE statement specifies a pointer that has undefined association status, or a pointer whose target was not created by allocation, an error occurs.

A pointer must not be deallocated if it is associated with an allocatable array, or it is associated with a portion of an object (such as an array element or an array section).

If a pointer is deallocated, the association status of any other pointer associated with the target (or portion of the target) becomes undefined.

Execution of a RETURN or END statement in a subprogram causes the pointer association status of any pointer declared (or accessed) in the procedure to become undefined, unless any of the following applies to the pointer:

- It has the SAVE attribute.
- It is in the scoping unit of a module that is accessed by another scoping unit which is currently executing.
- It is accessible by host association.
- It is in blank common.
- It is in a named common block that appears in another scoping unit that is currently executing.
- It is the return value of a function declared with the POINTER attribute.

If the association status of a pointer becomes undefined, it cannot subsequently be referenced or defined.

Examples

The following example shows deallocation of a pointer:

```fortran
INTEGER ERR
REAL, POINTER :: PTR_A(:)
...
ALLOCATE (PTR_A(10), STAT=ERR)
...
DEALLOCATE(PTR_A)
```

- DEALLOCATE Statement Overview
NULLIFY Statement Overview

The NULLIFY statement disassociates a pointer from its target. For more information, see NULLIFY.
Execution Control

A program normally executes statements in the order in which they are written. Executable control constructs and statements modify this normal execution by transferring control to another statement in the program, or by selecting blocks (groups) of constructs and statements for execution or repetition.

In Fortran 95/90, control constructs (CASE, DO, and IF) can be named. The name must be a unique identifier in the scoping unit, and must appear on the initial line and terminal line of the construct. On the initial line, the name is separated from the statement keyword by a colon (colon).

A block can contain any executable Fortran statement except an END statement. You can transfer control out of a block, but you cannot transfer control into another block.

DO loops cannot partially overlap blocks. The DO statement and its terminal statement must appear together in a statement block.

Branch Statements

Branching affects the normal execution sequence by transferring control to a labeled statement in the same scoping unit. The transfer statement is called the branch statement, while the statement to which the transfer is made is called the branch target statement.

Any executable statement can be a branch target statement, except for the following:

- CASE statement
- ELSE statement
- ELSE IF statement

Certain restrictions apply to the following statements:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Restriction</th>
</tr>
</thead>
<tbody>
<tr>
<td>DO terminal statement</td>
<td>The branch must be taken from within its nonblock DO construct.</td>
</tr>
<tr>
<td>END DO</td>
<td>The branch must be taken from within its block DO construct.</td>
</tr>
<tr>
<td>END IF</td>
<td>The branch should be taken from within its IF construct.</td>
</tr>
<tr>
<td>END SELECT</td>
<td>The branch must be taken from within its CASE construct.</td>
</tr>
</tbody>
</table>
### Statement

<table>
<thead>
<tr>
<th>Statement</th>

- DO constructs

### Unconditional GO TO Statement Overview

The unconditional GO TO statement transfers control to the same branch target statement every time it executes. For more information, see GOTO - Unconditional.

### Computed GO TO Statement Overview

The computed GO TO statement transfers control to one of a set of labeled branch target statements based on the value of an expression. For more information, see GOTO - COMPUTED.

### The ASSIGN and Assigned GO TO Statements Overview

The ASSIGN statement assigns a label to an integer variable. Subsequently, this variable can be used as a branch target statement by an assigned GO TO statement or as a format specifier in a formatted input/output statement.

The ASSIGN and assigned GO TO statements are deleted features in Fortran 95; they were obsolescent features in Fortran 90. Intel® Fortran fully supports features deleted in Fortran 95.
Arithmetic IF Statement Overview

The arithmetic IF statement conditionally transfers control to one of three statements, based on the value of an arithmetic expression. For more information, see IF - Arithmetic.

CALL Statement Overview

The CALL statement transfers control to a subroutine subprogram. For more information, see CALL.

CASE Constructs Overview

The CASE construct conditionally executes one block of constructs or statements depending on the value of a scalar expression in a SELECT CASE statement. For more information, see CASE.

CONTINUE Statement Overview

The CONTINUE statement is primarily used to terminate a labeled DO construct when the construct would otherwise end improperly with either a GO TO, arithmetic IF, or other prohibited control statement. For more information, see CONTINUE.

DO Constructs Overview

The DO construct controls the repeated execution of a block of statements or constructs. For more information, see DO.

- CYCLE Statement Overview
- EXIT Statement Overview
- Forms for DO Constructs
- Execution of DO Constructs
- DO WHILE Statement
- CYCLE Statement
• EXIT Statement

**Forms for DO Constructs**

A DO construct can be in block or nonblock form. For more information, see DO.

**Execution of DO Constructs**

The range of a DO construct includes all the statements and constructs that follow the DO statement, up to and including the terminal statement. If the DO construct contains another construct, the inner (nested) construct must be entirely contained within the DO construct.

Execution of a DO construct differs depending on how the loop is controlled, as follows:

• For simple DO constructs, there is no loop control. Statements in the DO range are repeated until the DO statement is terminated explicitly by a statement within the range.

• For iterative DO statements, loop control is specified as `do-var = expr1, expr2 [,expr3]`. An iteration count specifies the number of times the DO range is executed. (For more information, see Iteration Loop Control.)

• For DO WHILE statements, loop control is specified as a DO range. The DO range is repeated as long as a specified condition remains true. Once the condition is evaluated as false, the DO construct terminates. (For more information, see the DO WHILE statement.)

**See Also**

• DO Constructs Overview
• Iteration Loop Control
• Nested DO Constructs
• Extended Range
• Nested DO Constructs
• Extended Range

**Iteration Loop Control**

DO iteration loop control takes the following form:

```
do-var = expr1, expr2 [, expr3]
```

- `do-var` is the name of a scalar variable of type integer or real. It cannot be the name of an array element or structure component.
- `expr` is a scalar numeric expression of type integer, logical, or real. If it is not the same type as `do-var`, it is converted to that type.
Description

A DO variable or expression of type real is a deleted feature in Fortran 95; it was obsolescent in Fortran 90. Intel® Fortran fully supports features deleted in Fortran 95.

The following steps are performed in iteration loop control:

1. The expressions expr1, expr2, and expr3 are evaluated to respectively determine the initial, terminal, and increment parameters.
   - The increment parameter (expr3) is optional and must not be zero. If an increment parameter is not specified, it is assumed to be of type default integer with a value of 1.
2. The DO variable (do-var) becomes defined with the value of the initial parameter (expr1).
3. The iteration count is determined as follows:
   \[ \text{MAX}(\text{INT}((\text{expr2} - \text{expr1} + \text{expr3})/\text{expr3}), 0) \]
   - The iteration count is zero if either of the following is true:
     - expr1 > expr2 and expr3 > 0
     - expr1 < expr2 and expr3 < 0
4. The iteration count is tested. If the iteration count is zero, the loop terminates and the DO construct becomes inactive. (Compiler option f66 can affect this.) If the iteration count is nonzero, the range of the loop is executed.
5. The iteration count is decremented by one, and the DO variable is incremented by the value of the increment parameter, if any.

After termination, the DO variable retains its last value (the one it had when the iteration count was tested and found to be zero).

The DO variable must not be redefined or become undefined during execution of the DO range.

If you change variables in the initial, terminal, or increment expressions during execution of the DO construct, it does not affect the iteration count. The iteration count is fixed each time the DO construct is entered.

Examples

The following example specifies 25 iterations:

```fortran
DO 100 K=1,50,2
K=49 during the final iteration, K=51 after the loop.
```
The following example specifies 27 iterations:

DO 350 J=50,-2,-2

J=-2 during the final iteration, J=-4 after the loop.

The following example specifies 9 iterations:

DO NUMBER=5,40,4

NUMBER=37 during the final iteration, NUMBER=41 after the loop. The terminating statement of this DO loop must be END DO.

**See Also**

- Execution of DO Constructs
- Obsolescent and Deleted Language Features
- f66

**Nested DO Constructs**

A DO construct can contain one or more complete DO constructs (loops). The range of an inner nested DO construct must lie completely within the range of the next outer DO construct. Nested nonblock DO constructs can share a labeled terminal statement.
The following figure shows correctly and incorrectly nested DO constructs:
Figure 32: Nested DO Constructs
In a nested DO construct, you can transfer control from an inner construct to an outer construct. However, you cannot transfer control from an outer construct to an inner construct.

If two or more nested DO constructs share the same terminal statement, you can transfer control to that statement only from within the range of the innermost construct. Any other transfer to that statement constitutes a transfer from an outer construct to an inner construct, because the shared statement is part of the range of the innermost construct.

**Extended Range**

A DO construct has an extended range if both of the following are true:

- The DO construct contains a control statement that transfers control out of the construct.
- Another control statement returns control back into the construct after execution of one or more statements.

The range of the construct is extended to include all executable statements between the destination statement of the first transfer and the statement that returns control to the construct.

The following rules apply to a DO construct with extended range:

- A transfer into the range of a DO statement is permitted only if the transfer is made from the extended range of that DO statement.
- The extended range of a DO statement must not change the control variable of the DO statement.
The following figure shows valid and invalid extended range control transfers:
Figure 33: Control Transfers and Extended Range
**DO WHILE Statement Overview**

The **DO WHILE** statement executes the range of a **DO** construct while a specified condition remains true. For more information, see **DO WHILE**.

**CYCLE Statement Overview**

The **CYCLE** statement interrupts the current execution cycle of the innermost (or named) **DO** construct. For more information, see **CYCLE**.

**EXIT Statement Overview**

The **EXIT** statement terminates execution of a **DO** construct. For more information, see **EXIT**.

**END Statement Overview**

The **END** statement marks the end of a program unit. For more information, see **END**.

**IF Construct and Statement Overview**

The **IF construct** conditionally executes one block of statements or constructs.

The **IF statement** conditionally executes one statement.

The decision to transfer control or to execute the statement or block is based on the evaluation of a logical expression within the **IF** statement or construct.

**IF Construct Overview**

The **IF construct** conditionally executes one block of constructs or statements depending on the evaluation of a logical expression. For more information, see **IF construct**.

**IF Statement Overview**

The **IF statement** conditionally executes one statement based on the value of a logical expression. For more information, see **IF - Logical**.

**PAUSE Statement Overview**

The **PAUSE** statement temporarily suspends program execution until the user or system resumes execution. For more information, see **PAUSE**.
The PAUSE statement is a deleted feature in Fortran 95; it was an obsolescent feature in Fortran 90. Intel Fortran fully supports features deleted in Fortran 95.

**See Also**

- **Execution Control**
  For alternate methods of pausing while reading from and writing to a device, see **READ** and **WRITE**.

**RETURN Statement Overview**

The **RETURN** statement transfers control from a subprogram to the calling program unit. For more information, see **RETURN**.

**STOP Statement Overview**

The **STOP** statement terminates program execution before the end of the program unit. For more information, see **STOP**.
A Fortran 95/90 program consists of one or more program units. There are four types of program units:

- **Main program**
  The program unit that denotes the beginning of execution. It may or may not have a PROGRAM statement as its first statement.

- **External procedures**
  Program units that are either user-written functions or subroutines.

- **Modules**
  Program units that contain declarations, type definitions, procedures, or interfaces that can be shared by other program units.

- **Block data program units**
  Program units that provide initial values for variables in named common blocks.

A program unit does not have to contain executable statements; for example, it can be a module containing interface blocks for subroutines.

A procedure can be invoked during program execution to perform a specific task. There are several kinds of procedures, as follows:

<table>
<thead>
<tr>
<th>Kind of Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>External Procedure</td>
<td>A procedure that is not part of any other program unit.</td>
</tr>
<tr>
<td>Module Procedure</td>
<td>A procedure defined within a module</td>
</tr>
<tr>
<td>Internal Procedure²</td>
<td>A procedure (other than a statement function) contained within a main program, function, or subroutine</td>
</tr>
<tr>
<td>Intrinsic Procedure</td>
<td>A procedure defined by the Fortran language</td>
</tr>
<tr>
<td>Dummy Procedure</td>
<td>A dummy argument specified as a procedure or appearing in a procedure reference</td>
</tr>
<tr>
<td>Statement function</td>
<td>A computing procedure defined by a single statement</td>
</tr>
</tbody>
</table>

---

1897
<table>
<thead>
<tr>
<th>Kind of Procedure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. The program unit that contains an internal procedure is called its <em>host</em>.</td>
<td></td>
</tr>
</tbody>
</table>

*A function* is invoked in an expression using the name of the function or a defined operator. It returns a single value (function result) that is used to evaluate the expression.

*A subroutine* is invoked in a CALL statement or by a defined assignment statement. It does not directly return a value, but values can be passed back to the calling program unit through arguments (or variables) known to the calling program.

Recursion (direct or indirect) is permitted for functions and subroutines.

A procedure interface refers to the properties of a procedure that interact with or are of concern to the calling program. A procedure interface can be explicitly defined in interface blocks. All program units, except block data program units, can contain interface blocks.

**Main Program**

A main program is a program unit whose first statement is not a SUBROUTINE, FUNCTION, MODULE, or BLOCK DATA statement. Program execution always begins with the first executable statement in the main program, so there must be exactly one main program unit in every executable program. For more information, see `PROGRAM`.

**Modules and Module Procedures Overview**

A module program unit contains specifications and definitions that can be made accessible to other program units. There are two types of modules, intrinsic and nonintrinsic. Intrinsic modules are included in the Fortran library; nonintrinsic modules are user-defined.

For the module to be accessible, the other program units must reference its name in a USE statement, and the module entities must be public. For more information, see `MODULE`.

A module procedure is a procedure declared and defined in a module, between its CONTAINS and END statements. For more information, see `MODULE PROCEDURE`.

- USE Statement
Module References

A program unit references a module in a USE statement. This module reference lets the program unit access the public definitions, specifications, and procedures in the module.

Entities in a module are public by default, unless the USE statement specifies otherwise or the PRIVATE attribute is specified for the module entities.

A module reference causes use association between the using program unit and the entities in the module.

- Modules and Module Procedures Overview
- USE statement
- PRIVATE attribute
- PUBLIC attribute
- Use association

USE Statement Overview

The USE statement gives a program unit accessibility to public entities in a module. For more information, see USE.

Examples

Entities in modules can be accessed either through their given name, or through aliases declared in the USE statement of the main program unit. For example:

USE MODULE_LIB, XTABS => CROSSTABS

This statement accesses the routine called CROSSTABS in MODULE_LIB by the name XTABS. This way, if two modules have routines called CROSSTABS, one program can use them both simultaneously by assigning a local name in its USE statement.

When a program or subprogram renames a module entity, the local name (XTABS, in the preceding example) is accessible throughout the scope of the program unit that names it.

The ONLY option also allows public variables to be renamed. Consider the following:

USE MODULE_A, ONLY: VARIABLE_A => VAR_A

In this case, the host program accesses only VAR_A from module A, and refers to it by the name VARIABLE_A.
Consider the following example:

```fortran
MODULE FOO
  integer foos_integer
  PRIVATE
  integer foos_my_integer
END MODULE FOO
```

PRIVATE, in this case, makes the PRIVATE attribute the default for the entire module FOO. To make foos_integer accessible to other program units, add the line:

```fortran
PUBLIC :: foos_integer
```

Alternatively, to make only foos_my_integer inaccessible outside the module, rewrite the module as follows:

```fortran
MODULE FOO
  integer foos_integer
  integer, private:: foos_my_integer
END MODULE FOO
```

**Intrinsic Modules**

Intrinsic modules, like other module program units, contain specifications and definitions that can be made accessible to other program units. The intrinsic modules are part of the Fortran library. They are Fortran 2003 features.

An intrinsic module is specified in a USE statement, as follows:

```fortran
USE, INTRINSIC :: mod-name[, rename-list] ...
USE, INTRINSIC :: mod-name, ONLY :[, only-list]
```

- `mod-name` is the name of the intrinsic module.
- `rename-list` See the description in USE.
- `only-list` See the description in USE.

Procedures and types defined in an intrinsic module are not themselves intrinsic.

An intrinsic module can have the same name as other global entities, such as program units, common blocks, or external procedures. A scoping unit must not be able to access both an intrinsic module and a non-intrinsic module with the same name.

The following intrinsic modules are included in the Fortran library:
• ISO_C_BINDING
• ISO_FORTRAN_ENV
• IEEE Intrinsic Modules

ISO_C_BINDING Module
The ISO_C_BINDING intrinsic module provides access to data entities that are useful in mixed-language programming. It takes the following form:

USE, INTRINSIC :: ISO_C_BINDING

This intrinsic module provides access to the following data entities:

• Named Constants
• Derived Types
  Derived type C_PTR is interoperable with any C object pointer type. Derived type C_FUNPTR is interoperable with any C function pointer type.
• Intrinsic Module Procedures

Named Constants
The ISO_C_BINDING named constants represent kind type parameters of data representations compatible with C types.

Intrinsic-Type Constants
The following table shows interoperable Fortran types and C Types.

<table>
<thead>
<tr>
<th>Fortran Type</th>
<th>Named Constant for the KIND</th>
<th>C Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>C_INT</td>
<td>int</td>

</tr>
<tr>
<td>C_INT_LEAST8_T</td>
<td>int_least8_t</td>
<td></td>
</tr>
<tr>
<td>C_INT_LEAST16_T</td>
<td>int_least16_t</td>
<td></td>
</tr>
<tr>
<td>C_INT_LEAST32_T</td>
<td>int_least32_t</td>
<td></td>
</tr>
<tr>
<td>C_INT_LEAST64_T</td>
<td>int_least64_t</td>
<td></td>
</tr>
<tr>
<td>C_INT_FAST8_T</td>
<td>int_fast8_t</td>
<td></td>
</tr>
<tr>
<td>C_INT_FAST16_T</td>
<td>int_fast16_t</td>
<td></td>
</tr>
<tr>
<td>C_INT_FAST32_T</td>
<td>int_fast32_t</td>
<td></td>
</tr>
<tr>
<td>C_INT_FAST64_T</td>
<td>int_fast64_t</td>
<td></td>
</tr>
<tr>
<td>C_INTMAX_T</td>
<td>intmax_t</td>
<td></td>
</tr>
<tr>
<td>C_INTPTR_T</td>
<td>intptr_t</td>
<td></td>
</tr>
<tr>
<td>REAL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C_FLOAT</td>
<td>float</td>
<td></td>
</tr>
<tr>
<td>C_DOUBLE</td>
<td>double</td>
<td></td>
</tr>
<tr>
<td>C_LONG_DOUBLE</td>
<td>long double</td>
<td></td>
</tr>
<tr>
<td>COMPLEX</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C_FLOAT_COMPLEX</td>
<td>float _Complex</td>
<td></td>
</tr>
<tr>
<td>C_DOUBLE_COMPLEX</td>
<td>double _Complex</td>
<td></td>
</tr>
<tr>
<td>C_LONG_DOUBLE_COMPLEX</td>
<td>long double _Complex</td>
<td></td>
</tr>
</tbody>
</table>
For character type, the length type parameter must be omitted or it must be specified by an initialization expression whose value is one.

For example, an integer type with the kind type parameter C_LONG is interoperable with the C integer type "long" or any C type derived from "long".

The value of C_INT will be a valid value for an integer kind type parameter on the processor. The values for the other integer named constants (C_INT*) will be a valid value for an integer kind type parameter on the processor, if any, or one of the following:

- -1 if the C processor defines the corresponding C type and there is no interoperating Fortran processor kind
- -2 if the C processor does not define the corresponding C type

The values of C_FLOAT, C_DOUBLE, and C_LONGDOUBLE will be a valid value for a real kind type parameter on the processor, if any, or one of the following:

- -1 if the C processor's type does not have a precision equal to the precision of any of the Fortran processor's real kinds
- -2 if the C processor's type does not have a range equal to the range of any of the Fortran processor's real kinds
- -3 if the C processor's type has neither the precision or range equal to the precision or range of any of the Fortran processor's real kinds
- -4 if there is no interoperating Fortran processor or kind for other reasons

The values of C_FLOAT_COMPLEX, C_DOUBLE_COMPLEX, and C_LONG_DOUBLE_COMPLEX will be the same as those of C_FLOAT, C_DOUBLE, and C_LONG_DOUBLE, respectively.

The value of C_BOOL will be a valid value for a logical kind parameter on the processor, if any, or -1.

The value of C_CHAR is the character kind.
Character Constants

The following table shows interoperable named constants and C characters:

<table>
<thead>
<tr>
<th>Fortran Named Constant</th>
<th>Definition</th>
<th>C Character</th>
</tr>
</thead>
<tbody>
<tr>
<td>C_NULL_CHAR</td>
<td>null character</td>
<td>'\0'</td>
</tr>
<tr>
<td>C_ALERT</td>
<td>alert</td>
<td>'a'</td>
</tr>
<tr>

</tr>
<tr>
<td>C_CARRIAGE_RETURN</td>
<td>carriage return</td>
<td>'r'</td>
</tr>
<tr>
<td>C_HORIZONTAL_TAB</td>
<td>horizontal tab</td>
<td>'t'</td>
</tr>
<tr>
<td>C_VERTICAL_TAB</td>
<td>vertical tab</td>
<td>'v'</td>
</tr>
</tbody>
</table>

Derived-Type Constants

The constant C_NULL_PTR is of type C_PTR; it has the value of a C null data pointer. The constant C_NULL_FUNPTR is of type C_FUNPTR; it has the value of a C null function pointer.

Intrinsic Module Procedures

The following procedures are provided with the ISO_C_BINDING intrinsic module:

- C_ASSOCIATED
- C_F_POINTER
- C_F_PROCPOINTER
- C_FUNLOC
- C_LOC

None of the procedures are pure.

ISO_FORTRAN_ENV Module

The ISO_FORTRAN_ENV intrinsic module provides information about the Fortran run-time environment. It takes the following form:
USE, INTRINSIC :: ISO_FORTRAN_ENV

This intrinsic module provides the named constants you can use to get information on the Fortran environment. They are all scalars of type default integer.

<table>
<thead>
<tr>
<th>Named Constant</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER_STORAGE_SIZE</td>
<td>Is the size of the character storage unit expressed in bits.</td>
</tr>

<td>Is the value assigned to the variable specified in an IOSTAT= specifier if an end-of-record condition occurs during execution of an input/output statement and no error condition occurs.</td>
</tr>
<tr>
<td>NUMERIC_STORAGE_SIZE</td>
<td>Is the size of the numeric storage unit expressed in bits.</td>
</tr>
<tr>
<td>OUTPUT_UNIT</td>
<td>Identifies the preconnected external unit as the one specified by an asterisk in a WRITE statement. To use this constant, compiler option assume noold_unit_star must be enabled.</td>
</tr>
</tbody>
</table>
IEEE Intrinsic Modules and Procedures

Intel Fortran includes IEEE intrinsic modules that support IEEE arithmetic and exception handling. The modules contain derived data types that include named constants for controlling the level of support, and intrinsic module procedures. The modules and procedures are Fortran 2003 features.

To include an IEEE module in your program, specify the intrinsic module name in a USE statement; for example:

```
USE, INTRINSIC :: IEEE_ARITHMETIC
```

You must include the INTRINSIC attribute or the processor will look for a non-intrinsic module. Once you include a module, all related intrinsic procedures are defined.

There are three IEEE intrinsic modules described in this section:

- IEEE_ARITHMETIC
- IEEE_EXCEPTIONS
- IEEE_FEATURES

Determining Availability of IEEE Features

Before using a particular IEEE feature, you can determine whether your processor supports it by using the IEEE inquiry functions (listed in Table 1).

For example:

- To determine whether IEEE arithmetic is available for a particular kind of real, use intrinsic module function IEEE_SUPPORT_DATATYPE
- To determine whether you can change a rounding mode, use intrinsic module function IEEE_SUPPORT_ROUNDING.
- To determine whether a divide operation will be supported with the accuracy specified by the IEEE standard, use intrinsic module function IEEE_SUPPORT_DIVIDE.
- To determine whether you can control halting after an exception has occurred, use intrinsic module function IEEE_SUPPORT_HALTING.
- To determine which exceptions are supported in a scoping unit, use intrinsic module function IEEE_SUPPORT_FLAG.
- To determine whether all IEEE features are supported, use intrinsic module function IEEE_SUPPORT_STANDARD.
### Restrictions for IEEE Intrinsic Procedures

The following intrinsic procedures can only be invoked if IEEE_SUPPORT_DATATYPE is true for their arguments:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Required Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_CLASS</td>
<td>IEEE_SUPPORT_DENORMAL</td>
</tr>
<tr>
<td>IEEE_COPY_SIGN</td>
<td>IEEE_SUPPORT_DIVIDE</td>
</tr>
<tr>
<td>IEEE_IS_FINITE</td>
<td>IEEE_SUPPORT_INR</td>
</tr>
<tr>
<td>IEEE_NEGATIVE</td>
<td>IEEE_SUPPORT_IO</td>
</tr>
<tr>
<td>IEEE_IS_NORMAL</td>
<td>IEEE_SUPPORT_NAN</td>
</tr>
<tr>
<td>IEEE_LOGB</td>
<td>IEEE_SUPPORT_ROUNDING</td>
</tr>
<tr>
<td>IEEE_NEXT_AFTER</td>
<td>IEEE_SUPPORT_SQRT</td>
</tr>
<tr>
<td>IEEE_REM</td>
<td>IEEE_SUPPORT_UNORDERED</td>
</tr>
<tr>
<td>IEEE_RINT</td>
<td>IEEE_SUPPORT_VALUE</td>
</tr>
<tr>
<td>IEEE_SCALB</td>
<td>IEEE_VALUE</td>
</tr>
<tr>
<td>IEEE_SET_ROUNDING_MODE(^1)</td>
<td>IEEE_SUPPORT_ROUNDING</td>
</tr>
</tbody>
</table>

\(^1\): IEEE_SUPPORT_ROUNDING(ROUND_VALUE, X) must also be true.
For example, the IEEE_IS_NORMAL(X) function can only be invoked if
IEEE_SUPPORT_DATATYPE(X) has the value true. Consider the following:

USE, INTRINSIC :: IEEE_ARITHMETIC
...
IF IEEE_SUPPORT_DATATYPE(X) THEN
  IF IEEE_IS_NORMAL(X) THEN
    PRINT *, ' X is a 'normal' '
  ELSE
    PRINT *, ' X is not 'normal' '
  ELSE
    PRINT *, ' X is not a supported IEEE type '
ENDIF
...

Certain other IEEE intrinsic module procedures have similar restrictions:

- IEEE_IS_NAN(X) can only be invoked if IEEE_SUPPORT_NAN(X) has the value true.
- IEEE_SET_HALTING_MODE(FLAG, HALTING) can only be invoked if
  IEEE_SUPPORT_HALTING(FLAG) has the value true.
- IEEE_GET_UNDERFLOW_MODE(�ALDUAL) can only be invoked if
  IEEE_SUPPORT_UNDERFLOW_CONTROL(X) is true for some X.

For intrinsic module function IEEE_CLASS(X), some of the possible return values also have
restrictions. These restrictions are also true for argument CLASS in intrinsic module function
IEEE_VALUE(X, CLASS):

- IEEE_POSITIVE_INF and IEEE_NEGATIVE_INF can only be returned if IEEE_SUPPORT_INF(X)
  has the value true.
- IEEE_POSITIVE_DENORMAL and IEEE_NEGATIVE_DENORMAL can only be returned if
  IEEE_SUPPORT_DENORMAL(X) has the value true.
- IEEE_SIGNALING_NAN and IEEE_QUIET_NAN can only be returned if IEEE_SUPPORT_NAN(X)
  has the value true.

**IEEE_ARITHMETIC Intrinsic Module**

The IEEE_ARITHMETIC module contains derived data types that include named constants for
controlling the level of support, and intrinsic module procedures. This module and its procedures
are Fortran 2003 features.
The derived types in the intrinsic modules have components that are private. The IEEE_ARITHMETIC intrinsic module supports IEEE arithmetic and features. It defines the following derived types:

- **IEEE_CLASS_TYPE**: Identifies a class of floating-point values. Its values are the following named constants:

<table>
<thead>
<tr>
<th>IEEE_SIGNALING_NAN</th>
<th>IEEE_NEGATIVE_NORMAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_QUIET_NAN</td>
<td>IEEE_POSITIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_POSITIVE_INF</td>
<td>IEEE_NEGATIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_NEGATIVE_INF</td>
<td>IEEE_POSITIVE_ZERO</td>
</tr>
<tr>
<td>IEEE_POSITIVE_NORMAL</td>
<td>IEEE_NEGATIVE_ZERO</td>
</tr>
<tr>
<td>IEEE_OTHER_VALUE</td>
<td></td>
</tr>
</tbody>
</table>

- **IEEE_ROUND_TYPE**: Identifies a rounding mode. Its values are the following named constants:

<table>
<thead>
<tr>
<th>IEEE_NEAREST</th>
<th>IEEE_TO_ZERO</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_UP</td>
<td>IEEE_OTHER¹</td>
</tr>
<tr>
<td>IEEE_DOWN</td>
<td></td>
</tr>
</tbody>
</table>

1: Specifies the rounding mode does not conform to the IEEE standard.

The IEEE_ARITHMETIC intrinsic module also defines the following operators:

- Elemental operator `==` for two values of one of the above types to return true if the values are the same; otherwise, false.
- Elemental operator `!=` for two values of one of the above types to return true if the values differ; otherwise, false.

The IEEE_ARITHMETIC module includes support for IEEE_EXCEPTIONS module, and public entities in IEEE_EXCEPTIONS module are also public in the IEEE_ARITHMETIC module.

**IEEE_EXCEPTIONS Intrinsic Module**

The IEEE_EXCEPTIONS module contains derived data types that include named constants for controlling the level of support, and intrinsic module procedures. This module and its procedures are Fortran 2003 features.
The derived types in the intrinsic modules have components that are private. The IEEE_EXCEPTIONS intrinsic module supports the setting, clearing, saving, restoring, or testing of exception flags. It defines the following derived types:

- **IEEE_FLAG_TYPE**: Identifies an exception flag for errors that occur during an IEEE arithmetic operation or assignment. Its values are the following named constants:

<table>
<thead>
<tr>
<th>IEEE_INVALID</th>
<th>IEEE_DIVIDE_BY_ZERO</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_OVERFLOW</td>
<td>IEEE_INEXACT</td>
</tr>
<tr>
<td>IEEE_UNDERFLOW</td>
<td></td>
</tr>
</tbody>
</table>

Each of the above exceptions has a flag whose value is either quiet or signaling. The initial value is quiet and it signals when the associated exception occurs. To determine the value of a flag, use intrinsic module subroutine IEEE_GET_FLAG. To change the status for a flag, use intrinsic module subroutine IEEE_SET_FLAG or IEEE_SET_STATUS.

If a flag is signaling on entry to a procedure, the processor sets it to quiet on entry and restores it to signaling on return.

If a flag is quiet on entry to a procedure with access to modules IEEE_ARITHMETIC or IEEE_EXCEPTIONS, and is signaling on return, the processor will not restore it to quiet.

The IEEE_FLAG_TYPE module also defines the following named array constants:

- IEEE_USUAL = (/IEEE_OVERFLOW, IEEE_DIVIDE_BY_ZERO, IEEE_INVALID/)
- IEEE_ALL = (/IEEE_USUAL, IEEE_UNDERFLOW, IEEE_INEXACT/)

- **IEEE_STATUS_TYPE**: Saves the current floating-point status.

The IEEE_ARITHMETIC module includes support for IEEE_EXCEPTIONS module, and public entities in IEEE_EXCEPTIONS module are also public in the IEEE_ARITHMETIC module.

**IEEE_FEATURES Intrinsic Module**

The IEEE_FEATURES module contains derived data types that include named constants for controlling the level of support, and intrinsic module procedures. This module and its procedures are Fortran 2003 features.

The derived types in the intrinsic modules have components that are private. The IEEE_FEATURES intrinsic module supports specification of essential IEEE features. It defines the following derived types:

- **IEEE_FEATURES_TYPE**: Specifies IEEE features. Its values are the following named constants:

<table>
<thead>
<tr>
<th>IEEE_DATATYPE</th>
<th>IEEE_INF</th>
</tr>
</thead>
</table>

• **IEEE\_STATUS\_TYPE**: Saves the current floating-point status.

**IEEE Intrinsic Modules Quick Reference Tables**

This topic contains quick reference tables for categories of IEEE intrinsic modules.

1 : An elemental subroutine

**Block Data Program Units Overview**

A block data program unit provides initial values for nonpointer variables in named common blocks. For more information, see [BLOCK DATA](#).

**Examples**

An example of a block data program unit follows:

```fortran
BLOCK DATA WORK
    COMMON /WRKCOM/ A, B, C (10,10)
    DATA A /1.0/, B /2.0/, C /100*0.0/
END BLOCK DATA WORK
```

**Functions, Subroutines, and Statement Functions**

Functions, subroutines, and statement functions are user-written subprograms that perform computing procedures. The computing procedure can be either a series of arithmetic operations or a series of Fortran statements. A single subprogram can perform a computing procedure in several places in a program, to avoid duplicating a series of operations or statements in each place.

The following table shows the statements that define these subprograms, and how control is transferred to the subprogram:

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Defining Statements</th>
<th>Control Transfer Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
<td>FUNCTION or ENTRY</td>
<td>Function reference&lt;sup&gt;1&lt;/sup&gt;</td>
</tr>
<tr>
<td>Subroutine</td>
<td>SUBROUTINE or ENTRY</td>
<td>CALL statement&lt;sup&gt;2&lt;/sup&gt;</td>
</tr>
<tr>
<td>Statement function</td>
<td>Statement function definition</td>
<td>Function reference</td>
</tr>
</tbody>
</table>
A function can also be invoked by a defined operation (see Defining Generic Operators).

A subroutine can also be invoked by a defined assignment (see Defining Generic Assignment).

A function reference is used in an expression to invoke a function; it consists of the function name and its actual arguments. The function reference returns a value to the calling expression that is used to evaluate the expression.

General Rules for Function and Subroutine Subprograms

A subprogram can be an external, module, or internal subprogram. The END statement for an internal or module subprogram must be END SUBROUTINE [name] for a subroutine, or END FUNCTION [name] for a function. In an external subprogram, the SUBROUTINE and FUNCTION keywords are optional.

If a subprogram name appears after the END statement, it must be the same as the name specified in the SUBROUTINE or FUNCTION statement.

Function and subroutine subprograms can change the values of their arguments, and the calling program can use the changed values.

A SUBROUTINE or FUNCTION statement can be optionally preceded by an OPTIONS statement.

Dummy arguments (except for dummy pointers or dummy procedures) can be specified with an intent and can be made optional.
Recursive Procedures
A recursive procedure is a function or subroutine that references itself, either directly or indirectly. For more information, see RECURSIVE.

Pure Procedures
A pure procedure is a user-defined procedure that has no side effects. Pure procedures are a feature of Fortran 95. For more information, see PURE.

Elemental Procedures
An elemental procedure is a user-defined procedure that is a restricted form of pure procedure. For more information, see PURE and ELEMENTAL.

Functions Overview
A function subprogram is invoked in an expression and returns a single value (a function result) that is used to evaluate the expression. For more information, see FUNCTION.

See Also
• Functions, Subroutines, and Statement Functions
• RESULT Keyword Overview
• Function References
• RESULT Keyword
• Function References

RESULT Keyword Overview
If you use the RESULT keyword in a FUNCTION statement, you can specify a local variable name for the function result. For more information, see RESULT.

Function References
Functions are invoked by a function reference in an expression or by a defined operation.

A function reference takes the following form:

\[ \text{fun} \left( \left[ \text{a-arg} \ [, \text{a-arg}] \ldots \right] \right) \]

- \text{fun} \quad \text{Is the name of the function subprogram.}
- \text{a-arg} \quad \text{Is an actual argument optionally preceded by [keyword=], where keyword is the name of a dummy argument in the explicit interface for the function. The keyword is assigned a value when the procedure is invoked. Each actual argument must be a variable, an expression, or the name of a procedure. (It must not be the name of an internal procedure, statement function, or the generic name of a procedure.)}
Description

When a function is referenced, each actual argument is associated with the corresponding dummy argument by its position in the argument list or by the name of its keyword. The arguments must agree in type and kind parameters.

Execution of the function produces a result that is assigned to the function name or to the result name, depending on whether the RESULT keyword was specified.

The program unit uses the result value to complete the evaluation of the expression containing the function reference.

If positional arguments and argument keywords are specified, the argument keywords must appear last in the actual argument list.

If a dummy argument is optional, the actual argument can be omitted.

If a dummy argument is specified with the INTENT attribute, its use may be limited. A dummy argument whose intent is not specified is subject to the limitations of its associated actual argument.

An actual argument associated with a dummy procedure must be the specific name of a procedure, or be another dummy procedure. Certain specific intrinsic function names must not be used as actual arguments (see Functions Not Allowed as Actual Arguments).

Examples

Consider the following example:

```
X = 2.0
NEW_COS = COS(X) ! A function reference
```

Intrinsic function COS calculates the cosine of 2.0. The value -0.4161468 is returned (in place of COS(X)) and assigned to NEW_COS.

**Subroutines Overview**

A subroutine subprogram is invoked in a CALL statement or by a defined assignment statement, and does not return a particular value. For more information, see SUBROUTINE.

**Statement Functions Overview**

A statement function is a procedure defined by a single statement in the same program unit in which the procedure is referenced. For more information, see Statement Function.

**External Procedures**

External procedures are user-written functions or subroutines. They are located outside of the main program and can’t be part of any other program unit.

External procedures can be invoked by the main program or any procedure of an executable program.

In Fortran 95/90, external procedures can include internal subprograms (defining internal procedures). Internal subprograms are placed after a CONTAINS statement.

An external procedure can reference itself (directly or indirectly).

The interface of an external procedure is implicit unless an interface block is supplied for the procedure.

- Procedure Interfaces

*Building Applications* for details on passing arguments

**Internal Procedures**

Internal procedures are functions or subroutines that follow a CONTAINS statement in a program unit. The program unit in which the internal procedure appears is called its **host**.

Internal procedures can appear in the main program, in an external subprogram, or in a module subprogram.

An internal procedure takes the following form:
CONTAINS

internal-subprogram

[internal-subprogram] ...

internal-subprogram Is a function or subroutine subprogram that defines the procedure. An internal subprogram must not contain any other internal subprograms.

Description

Internal procedures are the same as external procedures, except for the following:

- Only the host program unit can use an internal procedure.
- An internal procedure has access to host entities by host association; that is, names declared in the host program unit are useable within the internal procedure.
- In Fortran 95/90, the name of an internal procedure must not be passed as an argument to another procedure. However, Intel® Fortran allows an internal procedure name to be passed as an actual argument to another procedure.
- An internal procedure must not contain an ENTRY statement.

An internal procedure can reference itself (directly or indirectly); it can be referenced in the execution part of its host and in the execution part of any internal procedure contained in the same host (including itself).

The interface of an internal procedure is always explicit.

Examples

The following example shows an internal procedure:

PROGRAM COLOR_GUIDE

...

CONTAINS

  FUNCTION HUE(BLUE)  ! An internal procedure

  ...

  END FUNCTION HUE

END PROGRAM
The following example program contains an internal subroutine `find`, which performs calculations that the main program then prints. The variables `a`, `b`, and `c` declared in the host program are also known to the internal subroutine.

```fortran
program INTERNAL
  ! shows use of internal subroutine and CONTAINS statement
  real a,b,c
  call find
  print *, c
contains
  subroutine find
    read *, a,b
    c = sqrt(a**2 + b**2)
  end subroutine find
end
```

- CONTAINS

**Argument Association**

Procedure arguments provide a way for different program units to access the same data. When a procedure is referenced in an executable program, the program unit invoking the procedure can use one or more *actual* arguments to pass values to the procedure's *dummy* arguments. The dummy arguments are associated with their corresponding actual arguments when control passes to the subprogram.

In general, when control is returned to the calling program unit, the last value assigned to a dummy argument is assigned to the corresponding actual argument.

An actual argument can be a variable, expression, or procedure name. The type and kind parameters, and rank of the actual argument must match those of its associated dummy argument.
A dummy argument is either a dummy data object, a dummy procedure, or an alternate return specifier (*). Except for alternate return specifiers, dummy arguments can be optional.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments.

A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

A scalar dummy argument can be associated with only a scalar actual argument.

If a dummy argument is an array, it must be no larger than the array that is the actual argument. You can use adjustable arrays to process arrays of different sizes in a single subprogram.

An actual argument associated with a dummy argument that is allocatable or a pointer must have the same type parameters as the dummy argument.

A dummy argument referenced as a subprogram must be associated with an actual argument that has been declared EXTERNAL or INTRINSIC in the calling routine.

If a scalar dummy argument is of type character, its length must not be greater than the length of its associated actual argument.

If the character dummy argument’s length is specified as *(*) (assumed length), it uses the length of the associated actual argument.

Once an actual argument has been associated with a dummy argument, no action can be taken that affects the value or availability of the actual argument, except indirectly through the dummy argument. For example, if the following statement is specified:

```fortran
CALL SUB_A (B(2:6), B(4:10))
```

B(4:6) must not be defined, redefined, or become undefined through either dummy argument, since it is associated with both arguments. However, B(2:3) is definable through the first argument, and B(7:10) is definable through the second argument.
Similarly, if any part of the actual argument is defined through a dummy argument, the actual argument can only be referenced through that dummy argument during execution of the procedure. For example, if the following statements are specified:

```fortran
MODULE MOD_A
  REAL :: A, B, C, D
END MODULE MOD_A

PROGRAM TEST
  USE MOD_A
  CALL SUB_1 (B)
...
END PROGRAM TEST

SUBROUTINE SUB_1 (F)
  USE MOD_A
...
  WRITE (*,*) F
END SUBROUTINE SUB_1
```

Variable B must not be directly referenced during the execution of SUB_1 because it is being defined through a dummy argument F. However, B can be indirectly referenced through F (and directly referenced when SUB_1 completes execution).

The following sections provide more details on arguments:

- **Optional arguments**
- **The different kinds of arguments:**
  - Array arguments
  - Pointer arguments
  - Assumed-length character arguments
  - Character constant and Hollerith arguments
  - Alternate return arguments
  - Dummy procedure arguments
- **References to generic procedures**
- **References to non-Fortran procedures** (%REF, %VAL, and %LOC)
Optional Arguments

Dummy arguments can be made optional if they are declared with the OPTIONAL attribute. In this case, an actual argument does not have to be supplied for it in a procedure reference.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments. A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

Positional arguments (if any) must appear first in an actual argument list, followed by keyword arguments (if any). If an optional argument is the last positional argument, it can simply be omitted if desired.

However, if the optional argument is to be omitted but it is not the last positional argument, keyword arguments must be used for any subsequent arguments in the list.

Optional arguments must have explicit procedure interfaces so that appropriate argument associations can be made.

The PRESENT intrinsic function can be used to determine if an actual argument is associated with an optional dummy argument in a particular reference.

The following example shows optional arguments:

```
PROGRAM RESULT
  TEST_RESULT = LGFUNC(A, B=D)
  ...
  CONTAINS
    FUNCTION LGFUNC(G, H, B)
      OPTIONAL H, B
      ...
    END FUNCTION
END
END
```

In the function reference, A is a positional argument associated with required dummy argument G. The second actual argument D is associated with optional dummy argument B by its keyword name (B). No actual argument is associated with optional argument H.
The following shows another example:

```fortran
! Arguments can be passed out of order, but must be
! associated with the correct dummy argument.
CALL EXT1 (Z=C, X=A, Y=B)
...
END
SUBROUTINE EXT1(X,Y,Z)
  REAL X, Y
  REAL, OPTIONAL :: Z
  ...
END SUBROUTINE
```

In this case, argument A is associated with dummy argument X by explicit assignment. Once EXT1 executes and returns, A is no longer associated with X, B is no longer associated with Y, and C is no longer associated with Z.

- OPTIONAL attribute
- PRESENT intrinsic function
- Argument association
- CALL
- Function References

**Array Arguments**

Arrays are sequences of elements. Each element of an actual array is associated with the element of the dummy array that has the same position in array element order.

If the dummy argument is an explicit-shape or assumed-size array, the size of the dummy argument array must not exceed the size of the actual argument array.

The type and kind parameters of an explicit-shape or assumed-size dummy argument must match the type and kind parameters of the actual argument, but their ranks need not match.

If the dummy argument is an assumed-shape array, the size of the dummy argument array is equal to the size of the actual argument array. The associated actual argument must not be an assumed-size array or a scalar (including a designator for an array element or an array element substring).
If the actual argument is an array section with a vector subscript, the associated dummy argument must not be defined.

The declaration of an array used as a dummy argument can specify the lower bound of the array.

If a dummy argument is allocatable, the actual argument must be allocatable and the type parameters and ranks must agree. An example of an allocatable function with allocatable arrays appears in `FUNCTION`.

Dummy argument arrays declared as assumed-shape, deferred-shape, or pointer arrays require an explicit interface visible to the caller.

**See Also**
- Argument Association
- Arrays
- Array association
- Argument association
- Array Elements
- Explicit-Shape Specifications
- Assumed-Shape Specifications
- Assumed-Size Specifications

**Pointer Arguments**

An argument is a pointer if it is declared with the `POINTER` attribute.

When a procedure is invoked, the dummy argument pointer receives the pointer association status of the actual argument. If the actual argument is currently associated, the dummy argument becomes associated with the same target.

The pointer association status of the dummy argument can change during the execution of the procedure, and any such changes are reflected in the actual argument.

If both the dummy and actual arguments are pointers, an explicit interface is required.

A dummy argument that is a pointer can be associated only with an actual argument that is a pointer. However, an actual argument that is a pointer can be associated with a nonpointer dummy argument. In this case, the actual argument is associated with a target and the dummy argument, through argument association, also becomes associated with that target.

If the dummy argument does not have the `TARGET` or `POINTER` attribute, any pointers associated with the actual argument do not become associated with the corresponding dummy argument when the procedure is invoked.
If the dummy argument has the TARGET attribute, and is either a scalar or assumed-shape array, and the corresponding actual argument has the TARGET attribute but is not an array section with a vector subscript, the following occurs:

- Any pointer associated with the actual argument becomes associated with the corresponding dummy argument when the procedure is invoked.
- Any pointers associated with the dummy argument remain associated with the actual argument when execution of the procedure completes.

If the dummy argument has the TARGET attribute, and is an explicit-shape or assumed-size array, and the corresponding actual argument has the TARGET attribute but is not an array section with a vector subscript, association of actual and corresponding dummy arguments when the procedure is invoked or when execution is completed is processor dependent.

If the dummy argument has the TARGET attribute and the corresponding actual argument does not have that attribute or is an array section with a vector subscript, any pointer associated with the dummy argument becomes undefined when execution of the procedure completes.

- Pointer assignments
- TARGET statement and attribute
- Argument association

Assumed-Length Character Arguments

An assumed-length character argument is a dummy argument that assumes the length attribute of its corresponding actual argument. An asterisk (*) specifies the length of the dummy character argument.

A character array dummy argument can also have an assumed length. The length of each element in the dummy argument is the length of the elements in the actual argument. The assumed length and the array declarator together determine the size of the assumed-length character array.
The following example shows an assumed-length character argument:

```fortran
INTEGER FUNCTION ICMAX(CVAR)
    CHARACTER*(*) CVAR
    ICMAX = 1
    DO I=2,LEN(CVAR)
        IF (CVAR(I:I) .GT. CVAR(ICMAX:ICMAX)) ICMAX=I
    END DO
    RETURN
END
```

The function ICMAX finds the position of the character with the highest ASCII code value. It uses the length of the assumed-length character argument to control the iteration. Intrinsic function LEN determines the length of the argument.

The length of the dummy argument is determined each time control transfers to the function. The length of the actual argument can be the length of a character variable, array element, substring, or expression. Each of the following function references specifies a different length for the dummy argument:

```fortran
CHARACTER VAR*10, CARRAY(3,5)*20
...
I1 = ICMAX(VAR)
I2 = ICMAX(CARRAY(2,2))
I3 = ICMAX(VAR(3:8))
I4 = ICMAX(CARRAY(1,3)(5:15))
I5 = ICMAX(VAR(3:4)//CARRAY(3,5))
```

See Also
- Argument Association
- LEN intrinsic function
- Argument association

Character Constant and Hollerith Arguments

If an actual argument is a character constant (for example, 'ABCD'), the corresponding dummy argument must be of type character. If an actual argument is a Hollerith constant (for example, 4HABCD), the corresponding dummy argument must have a numeric data type.
The following example shows character and Hollerith constants being used as actual arguments:

```fortran
SUBROUTINE S(CHARSUB, HOLLSUB, A, B)

EXTERNAL CHARSUB, HOLLSUB

...

CALL CHARSUB(A, 'STRING')

CALL HOLLSUB(B, 6HSTRING)
```

The subroutines CHARSUB and HOLLSUB are themselves dummy arguments of the subroutine S. Therefore, the actual argument 'STRING' in the call to CHARSUB must correspond to a character dummy argument, and the actual argument 6HSTRING in the call to HOLLSUB must correspond to a numeric dummy argument.

**See Also**
- Argument Association
- Argument association

**Alternate Return Arguments**

Alternate return (dummy) arguments can appear in a subroutine argument list. They cause execution to transfer to a labeled statement rather than to the statement immediately following the statement that called the routine. The alternate return is indicated by an asterisk (*). (An alternate return is an obsolescent feature in Fortran 90 and Fortran 95.)

There can be any number of alternate returns in a subroutine argument list, and they can be in any position in the list.

An actual argument associated with an alternate return dummy argument is called an alternate return specifier; it is indicated by an asterisk (*) or ampersand (&) followed by the label of an executable branch target statement in the same scoping unit as the CALL statement.

Alternate returns cannot be declared optional.

In Fortran 90, you can also use the RETURN statement to specify alternate returns.

The following example shows alternate return actual and dummy arguments:

```fortran
CALL MINN(X, Y, *300, *250, Z)

....

SUBROUTINE MINN(A, B, *, *, C)
```

- Argument Association
- Argument association
SUBROUTINE
CALL
RETURN
Obsolescent and Deleted Language Features

Dummy Procedure Arguments

If an actual argument is a procedure, its corresponding dummy argument is a dummy procedure. Dummy procedures can appear in function or subroutine subprograms.

The actual argument must be the specific name of an external, module, intrinsic, or another dummy procedure. If the specific name is also a generic name, only the specific name is associated with the dummy argument. Not all specific intrinsic procedures can appear as actual arguments. (For more information, see table Intrinsic Functions Not Allowed as Actual Arguments.)

The actual argument and corresponding dummy procedure must both be subroutines or both be functions.

If the interface of the dummy procedure is explicit, the type and kind parameters, and rank of the associated actual procedure must be the same as that of the dummy procedure.

If the interface of the dummy procedure is implicit and the procedure is referenced as a subroutine, the actual argument must be a subroutine or a dummy procedure.

If the interface of the dummy procedure is implicit and the procedure is referenced as a function or is explicitly typed, the actual argument must be a function or a dummy procedure.

Dummy procedures can be declared optional, but they must not be declared with an intent.

The following is an example of a procedure used as an argument:

```fortran
REAL FUNCTION LGFUNC(BAR)

INTERFACE
  REAL FUNCTION BAR(Y)
    REAL, INTENT(IN) :: Y
  END
END INTERFACE

... LGFUNC = BAR(2.0) ...

END FUNCTION LGFUNC
```

• Argument association

References to Generic Procedures
Generic procedures are procedures with different specific names that can be accessed under one generic (common) name. In FORTRAN 77, generic procedures were limited to intrinsic procedures. In the current Fortran standard, you can use generic interface blocks to specify generic properties for intrinsic and user-defined procedures.

If you refer to a procedure by using its generic name, the selection of the specific routine is based on the number of arguments and the type and kind parameters, and rank of each argument.

All procedures given the same generic name must be subroutines, or all must be functions. Any two must differ enough so that any invocation of the procedure is unambiguous.

The following sections describe references to generic intrinsic functions and show an example of using intrinsic function names.

References to Generic Intrinsic Functions
The generic intrinsic function name COS lists six specific intrinsic functions that calculate cosines: COS, DCOS, QCOS, CCOS, CDCOS, and CQCOS. These functions return different values: REAL(4), REAL(8), REAL(16), COMPLEX(4), COMPLEX(8), and COMPLEX(16) respectively.

If you invoke the cosine function by using the generic name COS, the compiler selects the appropriate routine based on the arguments that you specify. For example, if the argument is REAL(4), COS is selected; if it is REAL(8), DCOS is selected; and if it is COMPLEX(4), CCOS is selected.

You can also explicitly refer to a particular routine. For example, you can invoke the double-precision cosine function by specifying DCOS.

Procedure selection occurs independently for each generic reference, so you can use a generic reference repeatedly in the same program unit to access different intrinsic procedures.

You cannot use generic function names to select intrinsic procedures if you use them as follows:
• The name of a statement function
• A dummy argument name, a common block name, or a variable or array name

When an intrinsic function is passed as an actual argument to a procedure, its specific name must be used, and when called, its arguments must be scalar. Not all specific intrinsic functions can appear as actual arguments. (For more information, see Intrinsic Functions Not Allowed as Actual Arguments.)
A reference to a generic intrinsic procedure name in a program unit does not prevent use of the name for other purposes elsewhere in the program.

Normally, an intrinsic procedure name refers to the Fortran library procedure with that name. However, the name can refer to a user-defined procedure when the name appears in an EXTERNAL statement.

**NOTE.** If you call an intrinsic procedure by using the wrong number of arguments or an incorrect argument type, the compiler assumes you are referring to an external procedure. For example, intrinsic procedure SIN requires one argument; if you specify two arguments, such as SIN(10,4), the compiler assumes SIN is external and not intrinsic.

The data type of an intrinsic procedure does not change if you use an IMPLICIT statement to change the implied data type rules.

Intrinsic and user-defined procedures cannot have the same name if they appear in the same program unit.

**Examples**

The following example shows the local and global properties of an intrinsic function name. It uses the name SIN in different procedures as follows:

- The name of a statement function
- The generic name of an intrinsic function
- The specific name of an intrinsic function
- The name of a user-defined function
Using and Redefining an Intrinsic Function Name

! Compare ways of computing sine

PROGRAM SINES
  DOUBLE PRECISION X, PI
  PARAMETER (PI=3.141592653589793238D0)
  COMMON V(3)

! Define SIN as a statement function
  SIN(X) = COS(PI/2-X)
  print *
  print *, " Way of computing SIN(X)"
  print *
  print *, " X Statement Intrinsic Intrinsic User's "
  print *, " function DSIN SIN as arg SIN "
  print *
  DO X = -PI, PI, PI/2
    CALL COMPUT(X)
    WRITE (6,100) X, SIN(X), V
  END DO
100 FORMAT (5F12.7)
END

SUBROUTINE COMPUT(Y)
  DOUBLE PRECISION Y
  ! Use intrinsic function SIN - double-precision DSIN will be passed as an actual argument
  INTRINSIC SIN
  COMMON V(3)
END
! Makes the generic name SIN reference the double-precision sine DSIN
V(1) = SIN(Y)

! Use intrinsic function SIN as an actual argument - will pass DSIN
CALL SUB(REAL(Y),SIN)
END

SUBROUTINE SUB(A,S)

! Declare SIN as name of a user function
EXTERNAL SIN

! Declare SIN as type DOUBLE PRECISION
DOUBLE PRECISION SIN
COMMON V(3)

! Evaluate intrinsic function SIN passed as the dummy argument
V(2) = S(A)

! Evaluate user-defined SIN function
V(3) = SIN(A)
END

! Define the user SIN function
DOUBLE PRECISION FUNCTION SIN(X)

    INTEGER FACTOR
    SIN = X - X**3/FACTOR(3) + X**5/FACTOR(5) &
    & - X**7/FACTOR(7)
END

! Compute the factorial of N
INTEGER FUNCTION FACTOR(N)

    FACTOR = 1
    DO I=N,1,-1

    1933
FACTOR = FACTOR * I

END DO

END

1 The statement function named SIN is defined in terms of the generic function name COS. Because the argument of COS is double precision, the double-precision cosine function is evaluated. The statement function SIN is itself single precision.

2 The statement function SIN is called.

3 The name SIN is declared intrinsic so that the single-precision intrinsic sine function can be passed as an actual argument at 5.

4 The generic function name SIN is used to refer to the double-precision sine function.

5 The single-precision intrinsic sine function is used as an actual argument.

6 The name SIN is declared a user-defined function name.

7 The type of SIN is declared double precision.

8 The single-precision sine function passed at 5 is evaluated.

9 The user-defined SIN function is evaluated.

10 The user-defined SIN function is defined as a simple Taylor series using a user-defined function FACTOR to compute the factorial function.

References to Elemental Intrinsic Procedures

An elemental intrinsic procedure has scalar dummy arguments that can be called with scalar or array actual arguments. If actual arguments are array-valued, they must have the same shape. There are many elemental intrinsic functions, but only one elemental intrinsic subroutine (MVBITS).
If the actual arguments are scalar, the result is scalar. If the actual arguments are array-valued, the scalar-valued procedure is applied element-by-element to the actual argument, resulting in an array that has the same shape as the actual argument.

The values of the elements of the resulting array are the same as if the scalar-valued procedure had been applied separately to the corresponding elements of each argument.

For example, if A and B are arrays of shape (5,6), MAX(A, 0.0, B) is an array expression of shape (5,6) whose elements have the value MAX(A (i, j), 0.0, B (i, j)), where i = 1, 2,..., 5, and j = 1, 2,..., 6.

A reference to an elemental intrinsic procedure is an elemental reference if one or more actual arguments are arrays and all array arguments have the same shape.

**Examples**

Consider the following:

```fortran
REAL, DIMENSION (2) :: a, b
a(1) = 4; a(2) = 9
b = SQRT(a)  ! sets b(1) = SQRT(a(1)), and b(2) = SQRT(a(2))
```

**See Also**

- References to Generic Procedures
- Arrays
- Intrinsic Procedures

**References to Non-Fortran Procedures**

When a procedure is called, Fortran (by default) passes the address of the actual argument, and its length if it is of type character. To call non-Fortran procedures, you may need to pass the actual arguments in a form different from that used by Fortran.

The built-in functions %REF and %VAL let you change the form of an actual argument. You must specify these functions in the actual argument list of a CALL statement or function reference. You cannot use them in any other context.

%LOC computes the internal address of a storage item.

**Procedure Interfaces**

Every procedure has an interface, which consists of the name and characteristics of a procedure, the name and characteristics of each dummy argument, and the generic identifier (if any) by which the procedure can be referenced. The characteristics of a procedure are fixed, but the remainder of the interface can change in different scoping units.
If these properties are all known within the scope of the calling program, the procedure interface is explicit; otherwise it is implicit (deduced from its reference and declaration). The following table shows which procedures have implicit or explicit interfaces:

<table>
<thead>
<tr>
<th>Kind of Procedure</th>
<th>Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>External procedure</td>
<td>Implicit ¹</td>
</tr>
<tr>
<td>Module procedure</td>
<td>Explicit</td>
</tr>
<tr>
<td>Internal procedure</td>
<td>Explicit</td>
</tr>
<tr>
<td>Intrinsic procedure</td>
<td>Explicit</td>
</tr>
<tr>
<td>Dummy procedure</td>
<td>Implicit ¹</td>
</tr>
<tr>
<td>Statement function</td>
<td>Implicit</td>
</tr>
</tbody>
</table>

¹ Unless an interface block is supplied for the procedure.

The interface of a recursive subroutine or function is explicit within the subprogram that defines it.

An explicit interface can appear in a procedure's definition, in an interface block, or both. (Internal procedures must not appear in an interface block.)

The following sections describe when explicit interfaces are required, how to define explicit interfaces, and how to define generic names, operators, and assignment.
Examples
An example of an interface block follows:

INTERFACE
  SUBROUTINE Ext1 (x, y, z)
  REAL, DIMENSION (100,100) :: x, y, z
  END SUBROUTINE Ext1
  SUBROUTINE Ext2 (x, z)
  REAL x
  COMPLEX (KIND = 4) z (2000)
  END SUBROUTINE Ext2
  FUNCTION Ext3 (p, q)
  LOGICAL Ext3
  INTEGER p (1000)
  LOGICAL q (1000)
  END FUNCTION Ext3
END INTERFACE

Determining When Procedures Require Explicit Interfaces

A procedure must have an explicit interface in the following cases:

- If the procedure has any of the following:
  - A dummy argument that has the ALLOCATABLE, ASYNCHRONOUS, OPTIONAL, POINTER, TARGET, VALUE, or VOLATILE attribute
  - A dummy argument that is an assumed-shape array
  - A result that is an array, or a pointer, or is allocatable (functions only)
  - A result whose length is neither assumed nor a constant (character functions only)

- If a reference to the procedure appears as follows:
  - With an argument keyword
  - As a reference by its generic name
  - As a defined assignment (subroutines only)
• In an expression as a defined operator (functions only)
• In a context that requires it to be pure

• If the procedure is elemental

• Defining Generic Operators
• Defining Generic Assignment

Defining Explicit Interfaces

Interface blocks define explicit interfaces for external or dummy procedures. They can also be used to define a generic name for procedures, a new operator for functions, and a new form of assignment for subroutines.

See Also
• Procedure Interfaces
• INTERFACE

Defining Generic Names for Procedures

An interface block can be used to specify a generic name to reference all of the procedures within the interface block.

The initial line for such an interface block takes the following form:

INTERFACE generic-name

generic-name Is the generic name. It can be the same as any of the procedure names in the interface block, or the same as any accessible generic name (including a generic intrinsic name).
This kind of interface block can be used to extend or redefine a generic intrinsic procedure.

The procedures that are given the generic name must be the same kind of subprogram: all must be functions, or all must be subroutines.

Any procedure reference involving a generic procedure name must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

The following is an example of a procedure interface block defining a generic name:

```fortran
INTERFACE GROUP_SUBS
    SUBROUTINE INTEGER_SUB (A, B)
        INTEGER, INTENT(INOUT) :: A, B
    END SUBROUTINE INTEGER_SUB
    SUBROUTINE REAL_SUB (A, B)
        REAL, INTENT(INOUT) :: A, B
    END SUBROUTINE REAL_SUB
    SUBROUTINE COMPLEX_SUB (A, B)
        COMPLEX, INTENT(INOUT) :: A, B
    END SUBROUTINE COMPLEX_SUB
END INTERFACE
```

The three subroutines can be referenced by their individual specific names or by the group name GROUP_SUBS.

The following example shows a reference to INTEGER_SUB:

```fortran
INTEGER V1, V2
CALL GROUP_SUBS (V1, V2)
```
Consider the following:

```fortran
INTERFACE LINE_EQUATION
  SUBROUTINE REAL_LINE_EQ(X1,Y1,X2,Y2,M,B)
    REAL, INTENT(IN) :: X1,Y1,X2,Y2
    REAL, INTENT(OUT) :: M,B
  END SUBROUTINE REAL_LINE_EQ
  SUBROUTINE INT_LINE_EQ(X1,Y1,X2,Y2,M,B)
    INTEGER, INTENT(IN) :: X1,Y1,X2,Y2
    INTEGER, INTENT(OUT) :: M,B
  END SUBROUTINE INT_LINE_EQ
END INTERFACE
```

In this example, LINE_EQUATION is the generic name which can be used for either REAL_LINE_EQ or INT_LINE_EQ. Fortran selects the appropriate subroutine according to the nature of the arguments passed to LINE_EQUATION. Even when a generic name exists, you can always invoke a procedure by its specific name. In the previous example, you can call REAL_LINE_EQ by its specific name (REAL_LINE_EQ), or its generic name LINE_EQUATION.

Defining Generic Operators

An interface block can be used to define a generic operator. The only procedures allowed in the interface block are functions that can be referenced as defined operations.

The initial line for such an interface block takes the following form:

```fortran
INTERFACE OPERATOR (op)
  op
    Is one of the following:
    • A defined unary operator (one argument)
    • A defined binary operator (two arguments)
    • An extended intrinsic operator (number of arguments must be consistent with the intrinsic uses of that operator)
```

> 1940
The functions within the interface block must have one or two nonoptional arguments with intent IN, and the function result must not be of type character with assumed length. A defined operation is treated as a reference to the function.

The following shows the form (and an example) of a defined unary and defined binary operation:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defined Unary</td>
<td>.defined-operator. operand&lt;sup&gt;1&lt;/sup&gt;</td>
<td>.MINUS. C</td>
</tr>
<tr>
<td>Defined Binary</td>
<td>operand&lt;sup&gt;2&lt;/sup&gt;.defined-operator. operand&lt;sup&gt;3&lt;/sup&gt;</td>
<td>B .MINUS. C</td>
</tr>
</tbody>
</table>

<sup>1</sup> The operand corresponds to the function's dummy argument.

<sup>2</sup> The left operand corresponds to the first dummy argument of the function.

<sup>3</sup> The right operand corresponds to the second argument.

For intrinsic operator symbols, the generic properties include the intrinsic operations they represent. Both forms of each relational operator have the same interpretation, so extending one form (such as >=) defines both forms (>= and .GE.).

The following is an example of a procedure interface block defining a new operator:

```fortran
INTERFACE OPERATOR(.BAR.)
  FUNCTION BAR(A_1)
    INTEGER, INTENT(IN) :: A_1
    INTEGER :: BAR
  END FUNCTION BAR
END INTERFACE
```

The following example shows a way to reference function BAR by using the new operator:

```fortran
INTEGER B
I = 4 + (.BAR. B)
```
The following is an example of a procedure interface block with a defined operator extending an existing operator:

```
INTERFACE OPERATOR(+)
  FUNCTION LGFUNC (A, B)
    LOGICAL, INTENT(IN) :: A(:), B(SIZE(A))
    LOGICAL :: LGFUNC(SIZE(A))
  END FUNCTION LGFUNC
END INTERFACE
```

The following example shows two equivalent ways to reference function LGFUNC:

```
LOGICAL, DIMENSION(1:10) :: C, D, E
N = 10
E = LGFUNC(C(1:N), D(1:N))
E = C(1:N) + D(1:N)
```

**Defining Generic Assignment**

An interface block can be used to define generic assignment. The only procedures allowed in the interface block are subroutines that can be referenced as defined assignments.

The initial line for such an interface block takes the following form:

```
INTERFACE ASSIGNMENT (=)
```

The subroutines within the interface block must have two nonoptional arguments, the first with intent OUT or INOUT, and the second with intent IN.

A defined assignment is treated as a reference to a subroutine. The left side of the assignment corresponds to the first dummy argument of the subroutine; the right side of the assignment corresponds to the second argument.

The ASSIGNMENT keyword extends or redefines an assignment operation if both sides of the equal sign are of the same derived type.
Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE statement.

Any procedure reference involving generic assignment must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

The following is an example of a procedure interface block defining assignment:

```fortran
INTERFACE ASSIGNMENT (=)
  SUBROUTINE BIT_TO_NUMERIC (NUM, BIT)
    INTEGER, INTENT(OUT) :: NUM
    LOGICAL, INTENT(IN) :: BIT(:)
  END SUBROUTINE BIT_TO_NUMERIC
  SUBROUTINE CHAR_TO_STRING (STR, CHAR)
    USE STRING_MODULE ! Contains definition of type STRING
    TYPE(STRING), INTENT(OUT) :: STR ! A variable-length string
    CHARACTER(*) , INTENT(IN) :: CHAR
  END SUBROUTINE CHAR_TO_STRING
END INTERFACE
```

The following example shows two equivalent ways to reference subroutine BIT_TO_NUMERIC:

```fortran
CALL BIT_TO_NUMERIC(X, (NUM(I:J)))
X = NUM(I:J)
```

The following example shows two equivalent ways to reference subroutine CHAR_TO_STRING:

```fortran
CALL CHAR_TO_STRING(CH, '432C')
CH = '432C'
```

CONTAINS Statement Overview

This statement introduces internal or module procedures. For more information, see CONTAINS.

ENTRY Statement Overview

The ENTRY statement provides multiple entry points within a subprogram. It is not executable and must precede any CONTAINS statement (if any) within the subprogram. For more information, see ENTRY.

See Also

• Program Units and Procedures
• ENTRY Statements in Function Subprograms
• ENTRY Statements in Subroutine Subprograms
• ENTRY Statements in Function Subprograms
• ENTRY Statements in Subroutine Subprograms

ENTRY Statements in Function Subprograms

If the ENTRY statement is contained in a function subprogram, it defines an additional function. The name of the function is the name specified in the ENTRY statement, and its result variable is the entry name or the name specified by RESULT (if any).

If the entry result variable has the same characteristics as the FUNCTION statement's result variable, their result variables identify the same variable, even if they have different names. Otherwise, the result variables are storage associated and must all be nonpointer scalars of intrinsic type, in one of the following groups:

<table>
<thead>
<tr>
<th>Group</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group 1</td>
<td>Type default integer, default real, double precision real, default complex, double complex, or default logical</td>
</tr>
<tr>
<td>Group 2</td>
<td>Type REAL(16) and COMPLEX(16)</td>
</tr>
<tr>
<td>Group 3</td>
<td>Type default character (with identical lengths)</td>
</tr>
</tbody>
</table>

All entry names within a function subprogram are associated with the name of the function subprogram. Therefore, defining any entry name or the name of the function subprogram defines all the associated names with the same data type. All associated names with different data types become undefined.
If RESULT is specified in the ENTRY statement and RECURSIVE is specified in the FUNCTION statement, the interface of the function defined by the ENTRY statement is explicit within the function subprogram.

**Examples**

The following example shows a function subprogram that computes the hyperbolic functions SINH, COSH, and TANH:

```fortran
REAL FUNCTION TANH(X)
  TSINH(Y) = EXP(Y) - EXP(-Y)
  TCOSH(Y) = EXP(Y) + EXP(-Y)
  TANH = TSINH(X)/TCOSH(X)
  RETURN
ENTRY SINH(X)
  SINH = TSINH(X)/2.0
  RETURN
ENTRY COSH(X)
  COSH = TCOSH(X)/2.0
  RETURN
END
```

**See Also**
- ENTRY Statement Overview
- RESULT keyword

**ENTRY Statements in Subroutine Subprograms**

If the ENTRY statement is contained in a subroutine subprogram, it defines an additional subroutine. The name of the subroutine is the name specified in the ENTRY statement.

If RECURSIVE is specified on the SUBROUTINE statement, the interface of the subroutine defined by the ENTRY statement is explicit within the subroutine subprogram.
Examples
The following example shows a main program calling a subroutine containing an ENTRY statement:

```fortran
PROGRAM TEST
...
    CALL SUBA(A, B, C) ! A, B, and C are actual arguments
    ... ! passed to entry point SUBA
END
SUBROUTINE SUB(X, Y, Z)
...
    ENTRY SUBA(Q, R, S) ! Q, R, and S are dummy arguments
    ... ! Execution starts with this statement
END SUBROUTINE
```

The following example shows an ENTRY statement specifying alternate returns:

```fortran
CALL SUBC(M, N, *100, *200, P)
...
SUBROUTINE SUB(K, *, *)
...
    ENTRY SUBC(J, K, *, *, X)
    ... 
    RETURN 1
    RETURN 2
END
```

Note that the CALL statement for entry point SUBC includes actual alternate return arguments. The RETURN 1 statement transfers control to statement label 100 and the RETURN 2 statement transfers control to statement label 200 in the calling program.

IMPORT Statement Overview
The IMPORT statement makes host entities accessible in the interface body of an interface block. For more information, see IMPORT.
Intrinsic Procedures

Intrinsic procedures are functions and subroutines that are included in the Fortran library. There are four classes of these intrinsic procedures, as follows:

- **Elemental procedures**
  
  These procedures have scalar dummy arguments that can be called with scalar or array actual arguments. There are many elemental intrinsic functions and one elemental intrinsic subroutine (MVBITS).
  
  If the arguments are all scalar, the result is scalar. If an actual argument is array-valued, the intrinsic procedure is applied to each element of the actual argument, resulting in an array that has the same shape as the actual argument.
  
  If there is more than one array-valued argument, they must all have the same shape.
  
  Many algorithms involving arrays can now be written conveniently as a series of computations with whole arrays. For example, consider the following:
  
  ```fortran
  a = b + c
  ... ! a, b, c, and s are all arrays of similar shape
  s = sum(a)
  ```
  
  The above statements can replace entire DO loops.
  
  Consider the following:
  
  ```fortran
  real, dimension (5,5) x,y
  . . . !Assign values to x.
  y = sin(x) !Pass the entire array as an argument.
  ```
  
  In this example, since the SIN(X) function is an elemental procedure, it operates element-by-element on the array x when you pass it the name of the whole array.

- **Inquiry functions**
  
  These functions have results that depend on the properties of their principal argument, not the value of the argument (the argument value can be undefined).

- **Transformational functions**
  
  These functions have one or more array-valued dummy or actual arguments, an array result, or both. The intrinsic function is not applied elementally to an array-valued actual argument; instead it changes (transforms) the argument array into another array.

- **Nonelemental procedures**
These procedures must be called with only scalar arguments; they return scalar results. All subroutines (except MVBITS) are nonelemental.

Intrinsic procedures are invoked the same way as other procedures, and follow the same rules of argument association.

The intrinsic procedures have generic (or common) names, and many of the intrinsic functions have specific names. (Some intrinsic functions are both generic and specific.)

In general, generic functions accept arguments of more than one data type; the data type of the result is the same as that of the arguments in the function reference. For elemental functions with more than one argument, all arguments must be of the same type (except for the function MERGE).

When an intrinsic function is passed as an actual argument to a procedure, its specific name must be used, and when called, its arguments must be scalar. Some specific intrinsic functions are not allowed as actual arguments in all circumstances. The following table lists specific functions that cannot be passed as actual arguments.

### Table 595: Specific Intrinsic Functions Not Allowed as Actual Arguments

| AIMAX0 | FLOATI | IZEXT | LOC |
| AIMIN0 | FLOATJ | JFIX | MAX0 |
| AJMAX0 | FLOATK | JIDINT | MAX1 |
| AJMIN0 | FP_CLASS | JIFIX | MIN0 |
| AKMAX0 | HFIX | JINT | MIN1 |
| AKMIN0 | IADDR | JIQINT | MULT_HIGH |
| AMAX0 | IARGC | JMAX0 | MULT_HIGH_SIGNED |
| AMAX1 | ICHAR | JMAX1 | NARGS |
| AMIN0 | IDINT | JMIN0 | QCMPLX |
| AMIN1 | IFIX | JMIN1 | QEXT |
| CHAR | IIDINT | JNUM | QEXTD |
| CMPLX | IIIFIX | JZEXT | QMAX1 |
| DBLE | IINT | KIDINT | QMIN1 |
| DBLEQ | IIQINT | KIFIX | QNUM |
Note that none of the intrinsic subroutines can be passed as actual arguments.

This chapter also contains information on the following topics:

- Argument keywords in intrinsic procedures
- Overview of bit functions
- Categories and Lists of intrinsic procedures

The A to Z Reference contains the descriptions of all intrinsics listed in alphabetical order. Each reference entry indicates whether the procedure is inquiry, elemental, transformational, or nonelemental, and whether it is a function or a subroutine.

### Argument Keywords in Intrinsic Procedures

For all intrinsic procedures, the arguments shown are the names you must use as keywords when using the keyword form for actual arguments. For example, a reference to function CMPLX(X, Y, KIND) can be written as follows:

Using positional arguments: \[ \text{CMPLX}(F, G, L) \]
Using argument keywords: \(^1\) CMPLX(KIND=L, Y=G, X=F)

\(^1\) Note that argument keywords can be written in any order.

Some argument keywords are optional (denoted by square brackets). The following describes some of the most commonly used optional arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACK</td>
<td>Specifies that a string scan is to be in reverse order (right to left).</td>
</tr>
<tr>
<td>DIM</td>
<td>Specifies a selected dimension of an array argument.</td>
</tr>
<tr>
<td>KIND</td>
<td>Specifies the kind type parameter of the function result.</td>
</tr>
<tr>
<td>MASK</td>
<td>Specifies that a mask can be applied to the elements of the argument array to exclude the elements that are not to be involved in an operation.</td>
</tr>
</tbody>
</table>

**Examples**

The syntax for the `DATE_AND_TIME` intrinsic subroutine shows four optional positional arguments: DATE, TIME, ZONE, and VALUES. The following shows some valid ways to specify these arguments:

```fortran
! Keyword example
CALL DATE_AND_TIME (ZONE=Z)

! Positional example
CALL DATE_AND_TIME (DATE, TIME, ZONE)
```

Overview of Bit Functions

Integer data types are represented internally in binary two's complement notation. Bit positions in the binary representation are numbered from right (least significant bit) to left (most significant bit); the rightmost bit position is numbered 0.

The intrinsic functions IAND, IOR, IEOR, and NOT operate on all of the bits of their argument (or arguments). Bit 0 of the result comes from applying the specified logical operation to bit 0 of the argument. Bit 1 of the result comes from applying the specified logical operation to bit 1 of the argument, and so on for all of the bits of the result.

The functions ISHFT and ISHFTC shift binary patterns.

The functions IBSET, IBCLR, BTEST, and IBITS and the subroutine MVBITS operate on bit fields. A bit field is a contiguous group of bits within a binary pattern. Bit fields are specified by a starting bit position and a length. A bit field must be entirely contained in its source operand.

For example, the integer 47 is represented by the following:

Binary pattern: 0...0101111
Bit position: n...6543210
Where n is the number of bit positions in the numeric storage unit.

You can refer to the bit field contained in bits 3 through 6 by specifying a starting position of 3 and a length of 4.

Negative integers are represented in two's complement notation. For example, the integer -47 is represented by the following:

Binary pattern: 1...1010001
Bit position: n...6543210
Where n is the number of bit positions in the numeric storage unit.

The value of bit position n is as follows:

1 for a negative number
0 for a non-negative number

All the high-order bits in the pattern from the last significant bit of the value up to bit n are the same as bit n.
IBITS and MVBITS operate on general bit fields. Both the starting position of a bit field and its length are arguments to these intrinsics. IBSET, IBCLR, and BTEST operate on 1-bit fields. They do not require a length argument.

For IBSET, IBCLR, and BTEST, the bit position range is as follows:

- 0 to 63 for INTEGER(8) and LOGICAL(8)
- 0 to 31 for INTEGER(4) and LOGICAL(4)
- 0 to 15 for INTEGER(2) and LOGICAL(2)
- 0 to 7 for BYTE, INTEGER(1), and LOGICAL(1)

For IBITS, the bit position can be any number. The length range is 0 to 63 on Intel® 64 architecture and IA-64 architecture; 0 to 31 on IA-32 architecture.

The following example shows IBSET, IBCLR, and BTEST:

```fortran
I = 4
J = IBSET (I,5)
PRINT *, 'J = ',J
K = IBCLR (J,2)
PRINT *, 'K = ',K
PRINT *, 'Bit 2 of K is ',BTEST(K,2)
END
```

The results are: J = 36, K = 32, and Bit 2 of K is F.

For optimum selection of performance and memory requirements, Intel Fortran provides the following integer data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(1)</td>
<td>1</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>8</td>
</tr>
</tbody>
</table>

The bit manipulation functions each have a generic form that operates on all of these integer types and a specific form for each type.
When you specify the intrinsic functions that refer to bit positions or that shift binary patterns within a storage unit, be careful that you do not create a value that is outside the range of integers representable by the data type. If you shift by an amount greater than or equal to the size of the object you’re shifting, the result is 0.

Consider the following:

```
INTEGER(2) I, J
I = 1
J = 17
I = ISHFT(I, J)
```

The variables I and J have INTEGER(2) type. Therefore, the generic function ISHFT maps to the specific function IISHFT, which returns an INTEGER(2) result. INTEGER(2) results must be in the range -32768 to 32767, but the value 1, shifted left 17 positions, yields the binary pattern 1 followed by 17 zeros, which represents the integer 131072. In this case, the result in I is 0.

The previous example would be valid if I was INTEGER(4), because ISHFT would then map to the specific function JISHFT, which returns an INTEGER(4) value.

If ISHFT is called with a constant first argument, the result will either be the default integer size or the smallest integer size that can contain the first argument, whichever is larger.

**Categories and Lists of Intrinsic Procedures**

This section describes the categories of generic intrinsic functions (including a summarizing table) and lists the intrinsic subroutines.

Intrinsic procedures are fully described (in alphabetical order) in the A to Z Reference.

**Categories of Intrinsic Functions**

Generic intrinsic functions can be divided into categories, as shown in the following table:

**Table 601: Categories of Intrinsic Functions**

<table>
<thead>
<tr>
<th>Category</th>
<th>Subcategory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>Computation</td>
<td>Elemental functions that perform type conversions or simple numeric operations: ABS, AIMAG, AINT, AMAX0, AMIN0, ANINT, CEILING, CMPLX, CONJG, DBLE, DCMPLX, DFLOAT, DIM, DNUM, DPROD, DREAL,</td>
</tr>
<tr>
<td>Category</td>
<td>Subcategory</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Manipulation</td>
<td>Elemental functions that return values related to the components of the model values associated with the actual value of the argument: EXPONENT, FRACTION, NEAREST, RRSPACING, SCALE, SET_EXPONENT, SPACING</td>
<td></td>
</tr>
<tr>
<td>Inquiry</td>
<td>Functions that return scalar values from the models associated with the type and kind parameters of their arguments: DIGITS, EPSILON, HUGE, ILEN, MAXEXPONENT, MINEXPONENT, PRECISION, RADIX, RANGE, SIZEOF, TINY</td>
<td></td>
</tr>
<tr>
<td>Transformational</td>
<td>Functions that perform vector and matrix multiplication: DOT_PRODUCT, MATMUL</td>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td>Kind type</td>
<td>Functions that return kind type parameters: KIND, SELECTED_CHAR_KIND, SELECTED_INT_KIND, SELECTED_REAL_KIND</td>
<td></td>
</tr>
<tr>
<td>Mathematical</td>
<td>Elemental functions that perform mathematical operations: ACOS, ACOSD, ACOSH, ASIN, ASIND, ASINH, ATAN, ATAND, ATAN2, ATAN2D, ATAND, ATANH, COS, COSD, COSH, COTAN, COTAND, EXP, LOG, LOG10, SIN, SIND, SINH, SQRT, TAN, TAND, TANH</td>
<td></td>
</tr>
<tr>
<td>Bit</td>
<td>Manipulation</td>
<td>Elemental functions that perform single-bit processing, logical and shift operations, and allow bit subfields to be referenced: AND, BTTEST, DSHIFTL, DSHIFTR, IAND, IBCHNG, IBCLR, IBITS, IBSET, IEOR, IOR, ISHA, ISHC, ISHFT, ISHFTC, ISHL, IXOR, LSHIFT, NOT, OR, RSHIFT, SHIFTL, SHIFTR, XOR</td>
</tr>
<tr>
<td></td>
<td>Inquiry</td>
<td>Function that lets you determine parameter $s$ (the bit size) in the bit model: BIT_SIZE</td>
</tr>
<tr>
<td></td>
<td>Representation</td>
<td>Elemental functions that return information on bit representation of integers: LEADZ, POPCNT, POPPAR, TRAILZ</td>
</tr>
<tr>
<td>Category</td>
<td>Subcategory</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Character</td>
<td>Comparison</td>
<td>Elemental functions that make a lexical comparison of the character-string arguments and return a default logical result: LGE, LGT, LLE, LLT</td>
</tr>
<tr>
<td></td>
<td>Conversion</td>
<td>Elemental functions that take character arguments and return integer, ASCII, or character values: ACHAR, CHAR, IACHAR, ICHAR</td>
</tr>
<tr>
<td></td>
<td>String handling</td>
<td>Functions that perform operations on character strings, return lengths of arguments, and search for certain arguments: Elemental: ADJUSTL, ADJUSTR, INDEX, LEN_TRIM, SCAN, VERIFY; Nonelemental: REPEAT, TRIM</td>
</tr>
<tr>
<td></td>
<td>Inquiry</td>
<td>Functions that return the length of an argument or information about command-line arguments: COMMAND_ARGUMENT_COUNT, IARG, IARGC, LEN, NARGS, NUMARG</td>
</tr>
<tr>
<td>Array</td>
<td>Construction</td>
<td>Functions that construct new arrays from the elements of existing arrays: Elemental: MERGE; Nonelemental: PACK, SPREAD, UNPACK</td>
</tr>
<tr>
<td></td>
<td>Inquiry</td>
<td>Functions that let you determine if an array argument is allocated, and return the size or shape of an array, and the lower and upper bounds</td>
</tr>

</tr>
</tbody>
</table>
All of the numeric manipulation, and many of the numeric inquiry functions are defined by the model sets for integers and reals.

The value of the argument does not have to be defined.

For more information on bit functions, see Bit functions.

The Intel® Fortran processor character set is ASCII, so ACHAR = CHAR and IACHAR = ICHAR.

The following table summarizes the generic intrinsic functions and indicates whether they are elemental, inquiry, or transformational functions. Optional arguments are shown within square brackets.

Some intrinsic functions are specific with no generic association. These functions are listed below.

### Table 602: Summary of Generic Intrinsic Functions

<table>

<tr>
<td>------------------------</td>
<td>-------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ISHL (I, SHIFT)</td>
<td>E</td>
<td>Argument I logically shifted left or right by a specified number of bits</td>
</tr>
<tr>
<td>ISNAN (X)</td>
<td>E</td>
<td>Tests for Not-a-Number (NaN) values</td>
</tr>
<tr>
<td>IXOR (I, J)</td>
<td>E</td>
<td>See IOR</td>
</tr>
<tr>
<td>KIND (X)</td>
<td>I</td>
<td>The kind type parameter of the argument</td>
</tr>
<tr>
<td>LBOUND (ARRAY [,DIM] [,KIND])</td>
<td>I</td>
<td>The lower bounds of an array (or one of its dimensions)</td>
</tr>
<tr>
<td>LEADZ (I)</td>
<td>E</td>
<td>The number of leading zero bits in an integer</td>
</tr>
<tr>
<td>LEN (STRING [,KIND])</td>
<td>I</td>
<td>The length (number of characters) of the argument character string</td>
</tr>
<tr>
<td>LEN_TRIM (STRING [,KIND])</td>
<td>E</td>
<td>The length of the specified string without trailing blanks</td>
</tr>
<tr>
<td>LGE (STRING_A, STRING_B)</td>
<td>E</td>
<td>A logical value determined by a &gt; or = comparison of the arguments</td>
</tr>
<tr>
<td>LGT (STRING_A, STRING_B)</td>
<td>E</td>
<td>A logical value determined by a &gt; comparison of the arguments</td>
</tr>
<tr>
<td>LLE (STRING_A, STRING_B)</td>
<td>E</td>
<td>A logical value determined by a &lt; or = comparison of the arguments</td>
</tr>
<tr>
<td>LLT (STRING_A, STRING_B)</td>
<td>E</td>
<td>A logical value determined by a &lt; comparison of the arguments</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>

<tr>
<td>---------------------------</td>
<td>-------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LOC (A)</td>
<td>I</td>
<td>The internal address of the argument.</td>
</tr>
<tr>
<td>LOG (X)</td>
<td>E</td>
<td>The natural logarithm of the argument</td>
</tr>
<tr>
<td>LOG10 (X)</td>
<td>E</td>
<td>The common logarithm (base 10) of the argument</td>
</tr>
<tr>
<td>LOGICAL (L [,KIND])</td>
<td>E</td>
<td>The logical value of the argument converted to a logical of type KIND</td>
</tr>
<tr>
<td>LSHIFT (I, POSITIVE_SHIFT)</td>
<td>E</td>
<td>See ISHFT</td>
</tr>
<tr>
<td>LSHFT (I, POSITIVE_SHIFT)</td>
<td>E</td>
<td>Same as LSHIFT; see ISHFT</td>
</tr>
<tr>
<td>MALLOC (I)</td>
<td>E</td>
<td>The starting address for the block of memory allocated</td>
</tr>
<tr>
<td>MATMUL (MATRIX_A, MATRIX_B)</td>
<td>T</td>
<td>The result of matrix multiplication (also called a matrix multiply function)</td>
</tr>
<tr>
<td>MAX (A1, A2 [, A3,...])</td>
<td>E</td>
<td>The maximum value in the set of arguments</td>
</tr>
<tr>
<td>MAX1 (A1, A2 [, A3,...])</td>
<td>E</td>
<td>The maximum value in the set of real arguments (returned as an integer)</td>
</tr>
<tr>
<td>MAXEXPONENT (X)</td>
<td>I</td>
<td>The maximum exponent in the model for the argument</td>
</tr>
<tr>
<td>MAXLOC (ARRAY [,DIM] [,MASK] [,KIND])</td>
<td>T</td>
<td>The rank-one array that has the location of the maximum element in the argument array</td>
</tr>
<tr>
<td>MAXVAL (ARRAY [,DIM] [,MASK])</td>
<td>T</td>
<td>The maximum value of the elements in the argument array</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>------------------</td>
<td>-------</td>
<td>----------------</td>
</tr>
<tr>
<td>MERGE (TSOURCE, FSOURCE, MASK)</td>
<td>E</td>
<td>An array that is the combination of two conformable arrays (under a mask)</td>
</tr>
<tr>
<td>MIN (A1, A2 [, A3,...])</td>
<td>E</td>
<td>The minimum value in the set of arguments</td>
</tr>
<tr>
<td>MIN1 (A1, A2 [, A3,...])</td>
<td>E</td>
<td>The minimum value in the set of real arguments (returned as an integer)</td>
</tr>
<tr>
<td>MINEXPONENT (X)</td>
<td>I</td>
<td>The minimum exponent in the model for the argument</td>
</tr>
<tr>
<td>MINLOC (ARRAY [,DIM] [,MASK] [,KIND])</td>
<td>T</td>
<td>The rank-one array that has the location of the minimum element in the argument array</td>
</tr>
<tr>
<td>MINVAL (ARRAY [,DIM] [,MASK])</td>
<td>T</td>
<td>The minimum value of the elements in the argument array</td>
</tr>
<tr>
<td>MOD (A, P)</td>
<td>E</td>
<td>The remainder of the arguments (has the sign of the first argument)</td>
</tr>
<tr>
<td>MODULO (A, P)</td>
<td>E</td>
<td>The modulo of the arguments (has the sign of the second argument)</td>
</tr>
<tr>
<td>NEAREST (X, S)</td>
<td>E</td>
<td>The nearest different machine-representable number in a given direction</td>
</tr>
<tr>
<td>NEW_LINE (A)</td>
<td>I</td>
<td>A new line character</td>
</tr>
<tr>
<td>NINT (A [,KIND])</td>
<td>E</td>
<td>A real value rounded to the nearest integer</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NOT (I)</td>
<td>E</td>
<td>The logical complement of the argument</td>
</tr>
<tr>
<td>NULL ([MOLD])</td>
<td>T</td>
<td>A disassociated pointer</td>
</tr>
<tr>
<td>OR (I, J)</td>
<td>E</td>
<td>See IOR</td>
</tr>
<tr>
<td>PACK (ARRAY, MASK [,VECTOR])</td>
<td>T</td>
<td>A packed array of rank one (under a mask)</td>
</tr>
<tr>
<td>POPCNT (I)</td>
<td>E</td>
<td>The number of 1 bits in the integer argument</td>
</tr>
<tr>
<td>POPPAR (I)</td>
<td>E</td>
<td>The parity of the integer argument</td>
</tr>
<tr>
<td>PRECISION (X)</td>
<td>I</td>
<td>The decimal precision (real or complex) of the argument</td>
</tr>
<tr>
<td>PRESENT (A)</td>
<td>I</td>
<td>.TRUE. if an actual argument has been provided for an optional dummy argument</td>
</tr>
<tr>
<td>PRODUCT (ARRAY [,DIM] [,MASK])</td>
<td>T</td>
<td>The product of the elements of the argument array</td>
</tr>
<tr>
<td>QEXT (A)</td>
<td>E</td>
<td>The corresponding REAL(16) precision value of the argument</td>
</tr>
<tr>
<td>QFLOAT (A)</td>
<td>E</td>
<td>The corresponding REAL(16) precision value of the integer argument</td>
</tr>
<tr>
<td>RADIX (X)</td>
<td>I</td>
<td>The base of the model for the argument</td>
</tr>
<tr>
<td>RANGE (X)</td>
<td>I</td>
<td>The decimal exponent range of the model for the argument</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------</td>
<td>--------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>REAL ([A [, KIND]])</td>
<td>E</td>
<td>The corresponding real value of the argument</td>
</tr>
<tr>
<td>REPEAT (STRING, NCOPIES)</td>
<td>T</td>
<td>The concatenation of zero or more copies of the specified string</td>
</tr>
<tr>
<td>RESHAPE (SOURCE, SHAPE [,PAD] [,ORDER])</td>
<td>T</td>
<td>An array that has a different shape than the argument array, but the same elements</td>
</tr>
<tr>
<td>RRSPACING (X)</td>
<td>E</td>
<td>The reciprocal of the relative spacing near the argument</td>
</tr>
<tr>
<td>RSHIFT (I, NEGATIVE_SHIFT)</td>
<td>E</td>
<td>See ISHFT</td>
</tr>
<tr>
<td>RSHIFT (I, NEGATIVE_SHIFT)</td>
<td>E</td>
<td>Same as RSHIFT; see ISHFT</td>
</tr>
<tr>
<td>SCALE (X, I)</td>
<td>E</td>
<td>The value of the exponent part (of the model for the argument) changed by a specified value</td>
</tr>
<tr>
<td>SCAN (STRING, SET [,BACK] [,KIND])</td>
<td>E</td>
<td>The position of the specified character (or set of characters) within a string</td>
</tr>
<tr>
<td>SELECTED_CHAR_KIND (NAME)</td>
<td>T</td>
<td>The value of the kind type parameter of the character set named by the argument</td>
</tr>
<tr>
<td>SELECTED_INT_KIND (R)</td>
<td>T</td>
<td>The integer kind parameter of the argument</td>
</tr>
<tr>
<td>SELECTED_REAL_KIND ([P [, R])]</td>
<td>T</td>
<td>The real kind parameter of the argument; one of the optional arguments must be specified</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>------------------</td>
<td>-------</td>
<td>----------------</td>
</tr>
<tr>
<td>SET_EXPONENT (X, I)</td>
<td>E</td>
<td>The value of the exponent part (of the model for the argument) set to a specified value</td>
</tr>
<tr>
<td>SHAPE (SOURCE [,KIND])</td>
<td>I</td>
<td>The shape (rank and extents) of an array or scalar</td>
</tr>
<tr>
<td>SHIFTL (IVALUE, ISHIFT)</td>
<td>E</td>
<td>Argument IVALUE shifted left by a specified number of bits</td>
</tr>
<tr>
<td>SHIFTR (IVALUE, ISHIFT)</td>
<td>E</td>
<td>Argument IVALUE shifted right by a specified number of bits</td>
</tr>
<tr>
<td>SIGN (A, B)</td>
<td>E</td>
<td>A value with the sign transferred from its second argument</td>
</tr>
<tr>
<td>SIN (X)</td>
<td>E</td>
<td>The sine of the argument, which is in radians</td>
</tr>
<tr>
<td>SIND (X)</td>
<td>E</td>
<td>The sine of the argument, which is in degrees</td>
</tr>
<tr>
<td>SINH (X)</td>
<td>E</td>
<td>The hyperbolic sine of the argument</td>
</tr>
<tr>
<td>SIZE (ARRAY [,DIM] [,KIND])</td>
<td>I</td>
<td>The size (total number of elements) of the argument array (or one of its dimensions)</td>
</tr>
<tr>
<td>SIZEOF (X)</td>
<td>I</td>
<td>The bytes of storage used by the argument</td>
</tr>
<tr>
<td>SNGL (X)</td>
<td>E</td>
<td>The corresponding real value of the argument</td>
</tr>
<tr>
<td>SPACING (X)</td>
<td>E</td>
<td>The value of the absolute spacing of model numbers near the argument</td>
</tr>
<tr>
<td>Generic Function</td>
<td>Class</td>
<td>Value Returned</td>
</tr>
<tr>
<td>------------------</td>
<td>-------</td>
<td>----------------</td>
</tr>
<tr>
<td>SPREAD (SOURCE, DIM, NCOPIES)</td>
<td>T</td>
<td>A replicated array that has an added dimension</td>
</tr>
<tr>
<td>SQRT (X)</td>
<td>E</td>
<td>The square root of the argument</td>
</tr>
<tr>
<td>SUM (ARRAY [,DIM] [,MASK])</td>
<td>T</td>
<td>The sum of the elements of the argument array</td>
</tr>
<tr>
<td>TAN (X)</td>
<td>E</td>
<td>The tangent of the argument, which is in radians</td>
</tr>
<tr>
<td>TAND (X)</td>
<td>E</td>
<td>The tangent of the argument, which is in degrees</td>
</tr>
<tr>
<td>TANH (X)</td>
<td>E</td>
<td>The hyperbolic tangent of the argument</td>
</tr>
<tr>
<td>TINY (X)</td>
<td>I</td>
<td>The smallest positive number in the model for the argument</td>
</tr>
<tr>
<td>TRAILZ (I)</td>
<td>E</td>
<td>The number of trailing zero bits in an integer</td>
</tr>
<tr>
<td>TRANSFER (SOURCE, MOLD [,SIZE])</td>
<td>T</td>
<td>The bit pattern of SOURCE converted to the type and kind parameters of MOLD</td>
</tr>
<tr>
<td>TRANSPOSE (MATRIX)</td>
<td>T</td>
<td>The matrix transpose for the rank-two argument array</td>
</tr>
<tr>
<td>TRIM (STRING)</td>
<td>T</td>
<td>The argument with trailing blanks removed</td>
</tr>
<tr>
<td>UBOUND (ARRAY [,DIM] [,KIND])</td>
<td>I</td>
<td>The upper bounds of an array (or one of its dimensions)</td>
</tr>
<tr>
<td>UNPACK (VECTOR, MASK, FIELD)</td>
<td>T</td>
<td>An array (under a mask) unpacked from a rank-one array</td>
</tr>
</tbody>
</table>
The position of the first character in a string that does not appear in the given set of characters

\[ \text{VERIFY (STRING, SET [,BACK] [,KIND])} \]

See IEOREXOR (I, J)

A zero-extended value of the argument

\[ \text{EVERIFY (STRING, SET [,BACK] [,KIND])} \]

1 An elemental subroutine
Data Transfer I/O Statements

Input/Output (I/O) statements can be used for data transfer, file connection, file inquiry, and file positioning. This section discusses data transfer and contains information on the following topics:

- An overview of records and files
- Components of data transfer statements
- Data transfer input statements:
  - READ statement
  - ACCEPT statement
- Data transfer output statements:
  - WRITE statement
  - PRINT and TYPE statements
  - REWRITE statement

File connection, file inquiry, and file positioning I/O statements are discussed in File Operation I/O Statements.

Records and Files

A record is a sequence of values or a sequence of characters. There are three kinds of Fortran records, as follows:

- Formatted
  A record containing formatted data that requires translation from internal to external form. Formatted I/O statements have explicit format specifiers (which can specify list-directed formatting) or namelist specifiers (for namelist formatting). Only formatted I/O statements can read formatted data.

- Unformatted
  A record containing unformatted data that is not translated from internal form. An unformatted record can also contain no data. The internal representation of unformatted data is processor-dependent. Only unformatted I/O statements can read unformatted data.

- Endfile
The last record of a file. An endfile record can be explicitly written to a sequential file by an ENDFILE statement.

A file is a sequence of records. There are two types of Fortran files, as follows:

- **External**
  A file that exists in a medium (such as computer disks or terminals) external to the executable program.
  Records in an external file must be either all formatted or all unformatted. There are two ways to access records in external files: sequential and direct access.
  In sequential access, records are processed in the order in which they appear in the file. In direct access, records are selected by record number, so they can be processed in any order.

- **Internal**
  Memory (internal storage) that behaves like a file. This type of file provides a way to transfer and convert data in memory from one format to another. The contents of these files are stored as scalar character variables.

**See Also**
- Data Transfer I/O Statements
- Building Applications for details on formatted and unformatted data transfers and external file access methods

**Components of Data Transfer Statements**

Data transfer statements take one of the following forms:

- `io-keyword(io-control-list)[io-list]`
- `io-keyword format [, io-list]`
- `io-keyword` is one of the following: ACCEPT, PRINT (or TYPE), READ, REWRITE, or WRITE.
- `io-control-list` is one or more of the following input/output (I/O) control specifiers:
  - `[UNIT=]io-unit`  ADVANCE  ERR  SIZE
  - `[FMT=]format`  END  IOSTAT
  - `[NML=]group`  EOR  REC
io-list Is an I/O list, which can contain variables (except for assumed-size arrays) or implied-DO lists. Output statements can contain constants or expressions.

format Is the nonkeyword form of a control-list format specifier (no FMT=).

If a format specifier ([FMT=]format) or namelist specifier ([NML=]group) is present, the data transfer statement is called a formatted I/O statement; otherwise, it is an unformatted I/O statement.

If a record specifier (REC=) is present, the data transfer statement is a direct-access I/O statement; otherwise, it is a sequential-access I/O statement.

If an error, end-of-record, or end-of-file condition occurs during data transfer, file positioning and execution are affected, and certain control-list specifiers (if present) become defined. (For more information, see Branch Specifiers.)

Following sections describe the I/O control list and I/O lists.

I/O Control List

The I/O control list specifies one or more of the following:

- The I/O unit to act upon ([UNIT=]io-unit)
  
  This specifier must be present; the rest are optional.

- The format (explicit or list-directed) to use for data editing; if explicit, the keyword form must appear ([FMT=])

- The namelist group name to act upon ([NML=]group)

- The number of a record to access (REC)

- The name of a variable that contains the completion status of an I/O operation (IOSTAT)

- The label of the statement that receives control if an error (ERR), end-of-file (END), or end-of-record (EOR) condition occurs

- Whether you want to use advancing or nonadvancing I/O (ADVANCE)

- The number of characters read from a record (SIZE) by a nonadvancing READ statement

- Whether you want to use asynchronous or synchronous I/O (ASYNCHRONOUS)

- The identifier for a pending data transfer operation (ID)

- The identifier for the file position in file storage units in a stream file (POS)

No control specifier can appear more than once, and the list must not contain both a format specifier and namelist group name specifier.

Control specifiers can take any of the following forms:
Keyword form

When the keyword form (for example, UNIT=io-unit) is used for all control-list specifiers in an I/O statement, the specifiers can appear in any order.

Nonkeyword form

When the nonkeyword form (for example, io-unit) is used for all control-list specifiers in an I/O statement, the io-unit specifier must be the first item in the control list. If a format specifier or namelist group name specifier is used, it must immediately follow the io-unit specifier.

Mixed form

When a mix of keyword and nonkeyword forms is used for control-list specifiers in an I/O statement, the nonkeyword values must appear first. Once a keyword form of a specifier is used, all specifiers to the right must also be keyword forms.

1982
• **ID Specifier**
• **POS Specifier**

**Unit Specifier**

The unit specifier identifies the I/O unit to be accessed. It takes the following form:

\[ \text{UNIT=} \text{io-unit} \]

- A scalar integer expression that refers to a specific file, I/O device, or pipe. **If necessary, the value is converted to integer data type before use.** The integer is in the range 0 through 2,147,483,643. Note that the predefined parameters FOR_K_PRINT_UNITNO, FOR_K_TYPE_UNITNO, FOR_K_ACCEPT_UNITNO, and FOR_K_READ_UNITNO may not be in that range.

  Units 5, 6, and 0 are associated with preconnected units.

- An asterisk (*). This is the default (or implicit) external unit, which is preconnected for formatted sequential access. You can also preconnect files by using an environment variable.

For external files, it identifies a logical unit and is one of the following:

- A scalar integer expression that refers to a specific file, I/O device, or pipe. **If necessary, the value is converted to integer data type before use.** The integer is in the range 0 through 2,147,483,643. Note that the predefined parameters FOR_K_PRINT_UNITNO, FOR_K_TYPE_UNITNO, FOR_K_ACCEPT_UNITNO, and FOR_K_READ_UNITNO may not be in that range.

  Units 5, 6, and 0 are associated with preconnected units.

- An asterisk (*). This is the default (or implicit) external unit, which is preconnected for formatted sequential access. You can also preconnect files by using an environment variable.

For internal files, \text{io-unit} identifies a scalar or array character variable that is an internal file. An internal file is designated internal storage space (a variable buffer) that is used with formatted (including list-directed) sequential READ and WRITE statements.

The \text{io-unit} must be specified in a control list. If the keyword UNIT is omitted, the \text{io-unit} must be first in the control list.

A unit number is assigned either explicitly through an OPEN statement or implicitly by the system. If a READ statement implicitly opens a file, the file's status is STATUS='OLD'. If a WRITE statement implicitly opens a file, the file's status is STATUS='UNKNOWN'.

If the internal file is a *scalar* character variable, the file has only one record; its length is equal to that of the variable.

If the internal file is an *array* character variable, the file has a record for each element in the array; each record's length is equal to one array element.

An internal file can be read only if the variable has been defined and a value assigned to each record in the file. If the variable representing the internal file is a pointer, it must be associated; if the variable is an allocatable array, it must be currently allocated.

Before data transfer, an internal file is always positioned at the beginning of the first character of the first record.

**Format Specifier**

The format specifier indicates the format to use for data editing. It takes the following form:

```
[FMT=]format
```

*format* is one of the following:

- The statement label of a FORMAT statement
  The FORMAT statement must be in the same scoping unit as the data transfer statement.
- An asterisk (*), indicating list-directed formatting
- A scalar default integer variable that has been assigned the label of a FORMAT statement (through an ASSIGN statement)
  The FORMAT statement must be in the same scoping unit as the data transfer statement.
- A character expression (which can be an array or character constant) containing the run-time format
  A default character expression must evaluate to a valid format specification. If the expression is an array, it is treated as if all the elements of the array were specified in array element order and were concatenated.
- The name of a numeric array (or array element) containing the format

If the keyword FMT is omitted, the format specifier must be the second specifier in the control list; the io-unit specifier must be first.

If a format specifier appears in a control list, a namelist group specifier must not appear.

See Also

- FORMAT statement
- Interaction between FORMAT statements and I/O lists
- Rules for List-Directed Sequential READ Statements
• Rules for List-Directed Sequential WRITE Statements

Namelist Specifier

The namelist specifier indicates namelist formatting and identifies the namelist group for data transfer. It takes the following form:

\[ \text{[NML=} \text{group} \]

*group* is the name of a namelist group previously declared in a NAMELIST statement.

If the keyword NML is omitted, the namelist specifier must be the second specifier in the control list; the io-unit specifier must be first.

If a namelist specifier appears in a control list, a format specifier must not appear.

See Also

• I/O Control List
• Rules for Namelist Sequential READ Statements
• Rules for Namelist Sequential WRITE Statements
• READ
• WRITE

Record Specifier

The record specifier identifies the number of the record for data transfer in a file connected for direct access. It takes the following form:

\[ \text{REC=} r \]

*r* is a scalar numeric expression indicating the record number. The value of the expression must be greater than or equal to 1, and less than or equal to the maximum number of records allowed in the file.

If necessary, the value is converted to integer data type before use.

If REC is present, no END specifier, * format specifier, or namelist group name can appear in the same control list.

See Also

• I/O Control List
• Alternative Syntax for a Record Specifier

I/O Status Specifier

The I/O status specifier designates a variable to store a value indicating the status of a data transfer operation. It takes the following form:

\[ \text{IOSTAT=} i\text{-var} \]
A scalar integer variable. When a data transfer statement is executed, `i-var` is set to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A positive integer</td>
<td>Indicating an error condition occurred.</td>
</tr>
<tr>
<td>A negative integer</td>
<td>Indicating an end-of-file or end-of-record condition occurred. The negative integers differ depending on which condition occurred.</td>
</tr>
<tr>
<td>Zero</td>
<td>Indicating no error, end-of-file, or end-of-record condition occurred.</td>
</tr>
</tbody>
</table>

Execution continues with the statement following the data transfer statement, or the statement identified by a branch specifier (if any).

An end-of-file condition occurs only during execution of a sequential READ statement; an end-of-record condition occurs only during execution of a nonadvancing READ statement.

- READ
- WRITE

*Building Applications* for details on the error numbers returned by IOSTAT

**Branch Specifiers**

A branch specifier identifies a branch target statement that receives control if an error, end-of-file, or end-of-record condition occurs. There are three branch specifiers, taking the following forms:

- `ERR=label`
- `END=label`
- `EOR=label`

Is the label of the branch target statement that receives control when the specified condition occurs. The branch target statement must be in the same scoping unit as the data transfer statement.
The following rules apply to these specifiers:

- **ERR**
  - The error specifier can appear in a sequential access READ or WRITE statement, a direct-access READ statement, or a REWRITE statement.

  - If an error condition occurs, the position of the file is indeterminate, and execution of the statement terminates.

  - If IOSTAT was specified, the IOSTAT variable becomes defined as a positive integer value.

  - If SIZE was specified (in a nonadvancing READ statement), the SIZE variable becomes defined as an integer value. If a label was specified, execution continues with the labeled statement.

- **END**
  - The end-of-file specifier can appear only in a sequential access READ statement.

  - An end-of-file condition occurs when no more records exist in a file during a sequential read, or when an end-of-file record produced by the ENDFILE statement is encountered. End-of-file conditions do not occur in direct-access READ statements.

  - If an end-of-file condition occurs, the file is positioned after the end-of-file record, and execution of the statement terminates.

  - If IOSTAT was specified, the IOSTAT variable becomes defined as a negative integer value.

  - If a label was specified, execution continues with the labeled statement.

- **EOR**
  - The end-of-record specifier can appear only in a formatted, sequential access READ statement that has the specifier ADVANCE='NO'(nonadvancing input).

  - An end-of-record condition occurs when a nonadvancing READ statement tries to transfer data from a position after the end of a record.

  - If an end-of-record condition occurs, the file is positioned after the current record, and execution of the statement terminates.

  - If IOSTAT was specified, the IOSTAT variable becomes defined as a negative integer value.

  - If PAD='YES' was specified for file connection, the record is padded with blanks (as necessary) to satisfy the input item list and the corresponding data edit descriptor. If SIZE was specified, the SIZE variable becomes defined as an integer value. If a label was specified, execution continues with the labeled statement.

If one of the conditions occurs, no branch specifier appears in the control list, but an IOSTAT specifier appears, execution continues with the statement following the I/O statement. If neither a branch specifier nor an IOSTAT specifier appears, the program terminates.

Building Applications: Using the END, EOR, and ERR Branch Specifiers for more details on branch target statements

Building Applications for details on error processing

AdvanceSpecifier

The advance specifier determines whether nonadvancing I/O occurs for a data transfer statement. It takes the following form:

\[
\text{ADVANCE} = c-\text{expr}
\]

\(c-\text{expr}\) is a scalar character expression that evaluates to 'YES' for advancing I/O or 'NO' for nonadvancing I/O. The default value is 'YES'. Trailing blanks in the expression are ignored. The values specified are without regard to case.

The ADVANCE specifier can appear only in a formatted, sequential data transfer statement that specifies an external unit. It must not be specified for list-directed or namelist data transfer.

Advancing I/O always positions a file at the end of a record, unless an error condition occurs. Nonadvancing I/O can position a file at a character position within the current record.

For details on advancing and nonadvancing I/O, see Building Applications.

See Also
• I/O Control List

Building Applications for details on advancing and nonadvancing I/O

AsynchronousSpecifier

The asynchronous specifier determines whether asynchronous I/O occurs for a data transfer statement. It takes the following form:

\[
\text{ASYNCHRONOUS} = i-\text{expr}
\]

\(i-\text{expr}\) is a scalar character initialization expression that evaluates to 'YES' for asynchronous I/O or 'NO' for synchronous I/O. The value 'YES' should not appear unless the data transfer statement specifies a file unit number for \(\text{io-unit}\). The default value is 'NO'.

1988
Trailing blanks in the expression are ignored. The values specified are without regard to case.

Asynchronous I/O is permitted only for external files opened with an OPEN statement that specifies ASYNCHRONOUS='YES'.

When an asynchronous I/O statement is executed, the pending I/O storage sequence for the data transfer operation is defined to be:

- The set of storage units specified by the I/O item list or by the NML= specifier
- The storage units specified by the SIZE= specifier

**Character Count Specifier**

The character count specifier defines a variable to contain the count of how many characters are read when a nonadvancing READ statement terminates. It takes the following form:

\[ \text{SIZE=} i\text{-var} \]

*i-var* is a scalar integer variable.

If PAD='YES' was specified for file connection, blanks inserted as padding are not counted.

The SIZE specifier can appear only in a formatted, sequential READ statement that has the specifier ADVANCE='NO' (nonadvancing input). It must not be specified for list-directed or namelist data transfer.

**ID Specifier**

The ID specifier identifies a pending data transfer operation for a specified unit. It takes the following form:

\[ \text{ID=} id\text{-var} \]

*id-var* is a scalar integer variable to be used as an identifier. This specifier can only be used if the value of ASYNCHRONOUS= *i-expr* is 'YES'.

If an ID specifier is used in a data transfer statement, a wait operation is performed for the operation. If it is omitted, wait operations are performed for all pending data transfers for the specified unit.

If an error occurs during the execution of a data transfer statement containing an ID specifier, the variable specified becomes undefined.

**POS Specifier**

The POS specifier identifies the file position in file storage units in a stream file (ACCESS='STREAM'). It takes the following form:

\[ \text{POS=} p \]
$p$

Is a scalar integer expression that specifies the file position. It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

Each file storage unit has a unique file position, represented by a positive integer. The first file storage unit is a file is at file position 1. The position of each subsequent file storage unit is one greater than that of its preceding file storage unit.

For a formatted file, the file storage unit is an eight-bit byte. For an unformatted file, the file storage unit is an eight-bit byte (if option assume byterecl is specified) or a 32-bit word (if option assume nobyterecl, the default, is specified).

I/O Lists

In a data transfer statement, the I/O list specifies the entities whose values will be transferred. The I/O list is either an implied-do list or a simple list of variables (except for assumed-size arrays).

In input statements, the I/O list cannot contain constants and expressions because these do not specify named memory locations that can be referenced later in the program.

However, constants and expressions can appear in the I/O lists for output statements because the compiler can use temporary memory locations to hold these values during the execution of the I/O statement.

If an input item is a pointer, it must be currently associated with a definable target; data is transferred from the file to the associated target. If an output item is a pointer, it must be currently associated with a target; data is transferred from the target to the file.

If an input or output item is an array, it is treated as if the elements (if any) were specified in array element order. For example, if ARRAY_A is an array of shape (2,1), the following input statements are equivalent:

```fortran
READ *, ARRAY_A
READ *, ARRAY_A(1,1), ARRAY_A(2,1)
```

However, no element of that array can affect the value of any expression in the input list, nor can any element appear more than once in an input list. For example, the following input statements are invalid:

```fortran
INTEGER B(50)
...
READ *, B(B)
READ *, B(B(1):B(10))
```

If an input or output item is an allocatable array, it must be currently allocated.
If an input or output item is a derived type, the following rules apply:

- Any derived-type component must be in the scoping unit containing the I/O statement.
- The derived type must not have a pointer component.
- In a formatted I/O statement, a derived type is treated as if all of the components of the structure were specified in the same order as in the derived-type definition.
- In an unformatted I/O statement, a derived type is treated as a single object.

**Simple List Items in I/O Lists**

In a data transfer statement, a simple list of items takes the following form:

```
item [, item] ...
```

- `item` is one of the following:
  - For input statements: a variable name
    The variable must not be an assumed-size array, unless one of the following appears in the last dimension: a subscript, a vector subscript, or a section subscript specifying an upper bound.
  - For output statements: a variable name, expression, or constant
    Any expression must not attempt further I/O operations on the same logical unit. For example, it must not refer to a function subprogram that performs I/O on the same logical unit.

The data transfer statement assigns values to (or transfers values from) the list items in the order in which the items appear, from left to right.

When multiple array names are used in the I/O list of an unformatted input or output statement, only one record is read or written, regardless of how many array name references appear in the list.

**Examples**

The following example shows a simple I/O list:

```
WRITE (6, 10) J, K(3), 4, (L+4)/2, N
```

When you use an array name reference in an I/O list, an input statement reads enough data to fill every item of the array. An output statement writes all of the values in the array.

Data transfer begins with the initial item of the array and proceeds in the order of subscript progression, with the leftmost subscript varying most rapidly. The following statement defines a two-dimensional array:

```
DIMENSION ARRAY(3,3)
```
If the name ARRAY appears with no subscripts in a READ statement, that statement assigns values from the input record(s) to ARRAY(1,1), ARRAY(2,1), ARRAY(3,1), ARRAY(1,2), and so on through ARRAY(3,3).

An input record contains the following values:
1,3,721.73

The following example shows how variables in the I/O list can be used in array subscripts later in the list:

```
DIMENSION ARRAY(3,3)
...
READ (1,30) J, K, ARRAY(J,K)
```

When the READ statement is executed, the first input value is assigned to J and the second to K, establishing the subscript values for ARRAY(J,K). The value 721.73 is then assigned to ARRAY(1,3). Note that the variables must appear before their use as array subscripts.

Consider the following derived-type definition and structure declaration:

```
TYPE EMPLOYEE
   INTEGER ID
   CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
...
TYPE(EMPLOYEE) :: CONTRACT ! A structure of type EMPLOYEE
```

The following statements are equivalent:

```
READ *, CONTRACT
READ *, CONTRACT%ID, CONTRACT%NAME
```
The following shows more examples:

! A variable and array element in iolist:

    REAL b(99)
    READ (*, 300) n, b(n) ! n and b(n) are the iolist

300 FORMAT (I2, F10.5) ! FORMAT statement telling what form the input data has

! A derived type and type element in iolist:

    TYPE YOUR_DATA
        REAL a
        CHARACTER(30) info
        COMPLEX cx
    END TYPE YOUR_DATA
    TYPE (YOUR_DATA) yd1, yd2
    yd1.a = 2.3
    yd1.info = "This is a type demo."
    yd1.cx = (3.0, 4.0)
    yd2.cx = (4.5, 6.7)

! The iolist follows the WRITE (*,500).

    WRITE (*, 500) yd1, yd2.cx

! The format statement tells how the iolist will be output.

500 FORMAT (F5.3, A21, F5.2, ',', F5.2, ' yd2.cx = (', F5.2, ',', F5.2, ' )')

! The output looks like:

! 2.300This is a type demo 3.00, 4.00 yd2.cx = ( 4.50, 6.70 )
The following example uses an array and an array section:

! An array in the iolist:
   INTEGER handle(5)
   DATA handle / 5*0 /
   WRITE (*, 99) handle
99   FORMAT (5I5)
! An array section in the iolist.
   WRITE (*, 100) handle(2:3)
100  FORMAT (2I5)

The following shows another example:

PRINT *,'(I5)', 2*3 ! The iolist is the expression 2*3.
The following example uses a namelist:

```fortran
! Namelist I/O:

    INTEGER int1
    LOGICAL log1
    REAL r1
    CHARACTER (20) char20

    NAMELIST /mylist/ int1, log1, r1, char20

    int1 = 1
    log1 = .TRUE.
    r1 = 1.0
    char20 = 'NAMELIST demo'

    OPEN (UNIT = 4, FILE = 'MYFILE.DAT', DELIM = 'APOSTROPHE')
    WRITE (UNIT = 4, NML = mylist)

    ! Writes the following:
    ! &MYLIST
    !   INT1 = 1,
    !   LOG1 = T,
    !   R1 = 1.000000,
    !   CHAR20 = 'NAMELIST demo '
    ! /

    REWIND(4)
    READ (4, mylist)
```

**See Also**

- I/O Lists
- I/O Lists

**Implied-DO Lists in I/O Lists**

In a data transfer statement, an implied-DO list acts as though it were a part of an I/O statement within a DO loop. It takes the following form:

```fortran
( list, do-var = expr 1, expr 2 [, expr 3] )
```
list is a list of variables, expressions, or constants (see Simple List Items in I/O Lists).

do-var is the name of a scalar integer or real variable. The variable must not be one of the input items in list.

expr are scalar numeric expressions of type integer or real. They do not all have to be the same type, or the same type as the DO variable.

The implied-DO loop is initiated, executed, and terminated in the same way as a DO construct. The list is the range of the implied-DO loop. Items in that list can refer to do-var, but they must not change the value of do-var.

Two nested implied-DO lists must not have the same (or an associated) DO variable.

Use an implied-DO list to do the following:

• Specify iteration of part of an I/O list
• Transfer part of an array
• Transfer array items in a sequence different from the order of subscript progression

If the I/O statement containing an implied-DO list terminates abnormally (with an END, EOR, or ERR branch or with an IOSTAT value other than zero), the DO variable becomes undefined.

Examples

The following two output statements are equivalent:

WRITE (3,200) (A,B,C, I=1,3) ! An implied-DO list

The following example shows nested implied-DO lists. Execution of the innermost list is repeated most often:

WRITE (6,150) ((FORM(K,L), L=1,10), K=1,10,2)

The inner DO loop is executed 10 times for each iteration of the outer loop; the second subscript (L) advances from 1 through 10 for each increment of the first subscript (K). This is the reverse of the normal array element order. Note that K is incremented by 2, so only the odd-numbered rows of the array are output.

In the following example, the entire list of the implied-DO list (P(1), Q(1,1), Q(1,2),...Q(1,10)) are read before I is incremented to 2:

READ (5,999) (P(I), (Q(I,J), J=1,10), I=1,5)
The following example uses fixed subscripts and subscripts that vary according to the implied-DO list:

```fortran
READ (3,5555) (BOX(1,J), J=1,10)
```

Input values are assigned to BOX(1,1) through BOX(1,10), but other elements of the array are not affected.

The following example shows how a DO variable can be output directly:

```fortran
WRITE (6,1111) (I, I=1,20)
```

Integers 1 through 20 are written.

Consider the following:

```fortran
INTEGER mydata(25)
READ (10, 9000) (mydata(I), I=6,10,1)
9000 FORMAT (5I3)
```

In this example, the *iolist* specifies to put the input data into elements 6 through 10 of the array called mydata. The third value in the implied-DO loop, the increment, is optional. If you leave it out, the increment value defaults to 1.

- I/O Lists

**READ Statements Overview**

The READ statement is a data transfer input statement. Data can be input from external sequential or direct-access records, or from internal records. For more information, see READ.

**See Also**

Forms for Sequential READ Statements

Sequential READ statements transfer input data from external sequential-access records. The statements can be formatted with format specifiers (which can use list-directed formatting) or namelist specifiers (for namelist formatting), or they can be unformatted.

A sequential READ statement takes one of the following forms:

**Formatted:**

READ form [, io-list]

**Formatted - List-Directed:**

READ * [, io-list]

**Formatted - Namelist:**

READ (eunit, nml-group [, iostat] [, err] [, end])

READ nml

**Unformatted:**

- READ
Rules for Formatted Sequential READ Statements

Formatted, sequential READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

For data transfer, the file must be positioned so that the record read is a formatted record or an end-of-file record.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is greater than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains. If more characters are required and nonadvancing input is in effect, an end-of-record condition occurs.

If the file is connected for unformatted I/O, formatted data transfer is prohibited.

Examples

The following example shows formatted, sequential READ statements:

```
READ (*, '(B)', ADVANCE='NO') C
READ (FMT=“(E2.4)”, UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

Rules for List-Directed Sequential READ Statements

List-directed, sequential READ statements translate data from character to binary form by using the data types of the corresponding I/O list item to determine the form of the data. The translated data is then assigned to the entities in the I/O list in the order in which they appear, from left to right.

If a slash ( / ) is encountered during execution, the READ statement is terminated, and any remaining input list items are unchanged.

If the file is connected for unformatted I/O, list-directed data transfer is prohibited.

List-Directed Records

A list-directed external record consists of a sequence of values and value separators. A value can be any of the following:

- A constant

  Each constant must be a literal constant of type integer, real, complex, logical, or character; or a nondelimited character string. Binary, octal, hexadecimal, Hollerith, and named constants are not permitted.

  In general, the form of the constant must be acceptable for the type of the list item. The data type of the constant determines the data type of the value and the translation from external to internal form. The following rules also apply:

  - A numeric list item can correspond only to a numeric constant, and a character list item can correspond only to a character constant. If the data types of a numeric list element and its corresponding numeric constant do not match, conversion is performed according to the rules for arithmetic assignment (see the table in Numeric Assignment Statements).
  - A complex constant has the form of a pair of real or integer constants separated by a comma and enclosed in parentheses. Blanks can appear between the opening parenthesis and the first constant, before and after the separating comma, and between the second constant and the closing parenthesis.
  - A logical constant represents true values (.TRUE. or any value beginning with T, .T, t, or .t) or false values (.FALSE. or any value beginning with F, .F, f, or .f).

A character string does not need delimiting apostrophes or quotation marks if the corresponding I/O list item is of type default character, and the following is true:

- The character string does not contain a blank, comma (,), or slash ( / ).
- The character string is not continued across a record boundary.
• The first nonblank character in the string is not an apostrophe or a quotation mark.
• The leading character is not a string of digits followed by an asterisk.

A nondelimited character string is terminated by the first blank, comma, slash, or end-of-record encountered. Apostrophes and quotation marks within nondelimited character strings are transferred as is.

• A null value

A null value is specified by two consecutive value separators (such as,,) or a nonblank initial value separator. (A value separator before the end of the record does not signify a null value.)

A null value indicates that the corresponding list element remains unchanged. A null value can represent an entire complex constant, but cannot be used for either part of a complex constant.

• A repetition of a null value (r*) or a constant (r*constant), where r is an unsigned, nonzero, integer literal constant with no kind parameter, and no embedded blanks.

A value separator is any number of blanks, or a comma or slash, preceded or followed by any number of blanks. When any of these appear in a character constant, they are considered part of the constant, not value separators.

The end of a record is equivalent to a blank character, except when it occurs in a character constant. In this case, the end of the record is ignored, and the character constant is continued with the next record (the last character in the previous record is immediately followed by the first character of the next record).

Blanks at the beginning of a record are ignored unless they are part of a character constant continued from the previous record. In this case, the blanks at the beginning of the record are considered part of the constant.

**Examples**

Suppose the following statements are specified:

```plaintext
CHARACTER*14 C
DOUBLE PRECISION T
COMPLEX D,E
LOGICAL L,M
READ (1,*) I,R,D,E,L,M,J,K,S,T,C,A,B
```

2001
Then suppose the following external record is read:

\[
4 \ 6.3 \ (3.4,4.2), \ (3, 2 ), \ T,F,,3 \times 14.6,'ABC,DEF/GHI''JK'/
\]

The following values are assigned to the I/O list items:

<table>
<thead>
<tr>
<th>I/O List Item</th>
<th>Value Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>4</td>
</tr>
<tr>
<td>R</td>
<td>6.3</td>
</tr>
<tr>
<td>D</td>
<td>(3.4,4.2)</td>
</tr>
<tr>
<td>E</td>
<td>(3.0,2.0)</td>
</tr>
<tr>
<td>L</td>
<td>.TRUE.</td>
</tr>
<tr>
<td>M</td>
<td>.FALSE.</td>
</tr>
<tr>
<td>J</td>
<td>Unchanged</td>
</tr>
<tr>
<td>K</td>
<td>14</td>
</tr>
<tr>
<td>S</td>
<td>14.6</td>
</tr>
<tr>
<td>T</td>
<td>14.6D0</td>
</tr>
<tr>
<td>C</td>
<td>ABC,DEF/GHI' JK</td>
</tr>
<tr>
<td>A</td>
<td>Unchanged</td>
</tr>
<tr>
<td>B</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>
The following example shows list-directed input and output:

```fortran
REAL a
INTEGER i
COMPLEX c
LOGICAL up, down

DATA a /2358.2E-8/, i /91585/, c /(705.60,819.60)/
DATA up /.TRUE./, down /.FALSE./

OPEN (UNIT = 9, FILE = 'listout', STATUS = 'NEW')
WRITE (9, *) a, i
WRITE (9, *) c, up, down
REWIND (9)
READ (9, *) a, i
READ (9, *) c, up, down
WRITE (*, *) a, i
WRITE (*, *) c, up, down
END
```

The preceding program produces the following output:

```
2.3582001E-05  91585
(705.6000,819.6000)  T  F
```

**Rules for Namelist Sequential READ Statement**

Namelist, sequential READ statements translate data from external to internal form by using the data types of the objects in the corresponding NAMELIST statement to determine the form of the data. The translated data is assigned to the specified objects in the namelist group in the order in which they appear, from left to right.
If a slash ( / ) is encountered during execution, the READ statement is terminated, and any remaining input list items are unchanged.

If the file is connected for unformatted I/O, namelist data transfer is prohibited.

**Namelist Records**

A namelist external record takes the following form:

```
&group-name object = value [, object = value] ... /
```

- **group-name**
  Is the name of the group containing the objects to be given values. The name must have been previously defined in a NAMELIST statement in the scoping unit. The name cannot contain embedded blanks and must be contained within a single record.

- **object**
  Is the name (or subobject designator) of an entity defined in the NAMELIST declaration of the group name. The object name must not contain embedded blanks except within the parentheses of a subscript or substring specifier. Each object must be contained in a single record.

- **value**
  Is any of the following:

  - A constant
    
    Each constant must be a literal constant of type integer, real, complex, logical, or character; or a nondelimited character string. Binary, octal, hexadecimal, Hollerith, and named constants are not permitted.
    
    In general, the form of the constant must be acceptable for the type of the list item. The data type of the constant determines the data type of the value and the translation from external to internal form. The following rules also apply:
    
    - A numeric list item can correspond only to a numeric constant, and a character list item can correspond only to a character constant. If the data types of a numeric list element and its corresponding numeric constant do not match, conversion is performed according to the rules for arithmetic assignment (see the table in Numeric Assignment Statements). Logical list items and logical constants are not considered numeric, unless the compiler option assume old_logical_ldio is specified.
• A complex constant has the form of a pair of real or integer constants separated by a comma and enclosed in parentheses. Blanks can appear between the opening parenthesis and the first constant, before and after the separating comma, and between the second constant and the closing parenthesis.

• A logical constant represents true values (.TRUE. or any value beginning with T, .T, t, or .t) or false values (.FALSE. or any value beginning with F, .F, f, or .f).

A character string does not need delimiting apostrophes or quotation marks if the corresponding NAMELIST item is of type default character, and the following is true:

• The character string does not contain a blank, comma (,), slash (/), exclamation point (!), ampersand (&), dollar sign ($), left parenthesis, equal sign (=), percent sign (%), or period (.). The character string is not continued across a record boundary.

• The first nonblank character in the string is not an apostrophe or a quotation mark.

• The leading characters are not a string of digits followed by an asterisk.

A nondelimited character string is terminated by the first blank, comma, slash, end-of-record, exclamation, ampersand, or dollar sign encountered. Apostrophes and quotation marks within nondelimited character strings are transferred as is.

If an equal sign, percent sign, or period is encountered while scanning for a nondelimited character string, the string is treated as a variable name (or part of one) and not as a nondelimited character string.

• A null value

A null value is specified by two consecutive value separators (such as,,) or a nonblank initial value separator. (A value separator before the end of the record does not signify a null value.)

A null value indicates that the corresponding list element remains unchanged. A null value can represent an entire complex constant, but cannot be used for either part of a complex constant.
• A repetition of a null value ($r*$) or a constant ($r*$constant), where $r$ is an unsigned, nonzero, integer literal constant with no kind parameter, and no embedded blanks.

Blanks can precede or follow the beginning ampersand (&), follow the group name, precede or follow the equal sign, or precede the terminating slash.

Comments (beginning with ! only) can appear anywhere in namelist input. The comment extends to the end of the source line.

If an entity appears more than once within the input record for a namelist data transfer, the last value is the one that is used.

If there is more than one object = value pair, they must be separated by value separators.

A value separator is any number of blanks, or a comma or slash, preceded or followed by any number of blanks. When any of these appear in a character constant, they are considered part of the constant, not value separators.

The end of a record is equivalent to a blank character, except when it occurs in a character constant. In this case, the end of the record is ignored, and the character constant is continued with the next record (the last character in the previous record is immediately followed by the first character of the next record).

Blanks at the beginning of a record are ignored unless they are part of a character constant continued from the previous record. In this case, the blanks at the beginning of the record are considered part of the constant.

**Prompting for Namelist Group Information**

During execution of a program containing a namelist READ statement, you can specify a question mark character (?) or a question mark character preceded by an equal sign (=?) to get information about the namelist group. The ? or =? must follow one or more blanks.

If specified for a unit capable of both input and output, the ? causes display of the group name and the objects in that group. The =? causes display of the group name, objects within that group, and the current values for those objects (in namelist output form). If specified for another type of unit, the symbols are ignored.
For example, consider the following statements:

```fortran
NAMELIST /NLIST/ A,B,C
REAL A /1.5/
INTEGER B /2/
CHARACTER*5 C /'ABCDE'/
READ (5,NML=NLIST)
WRITE (6,NML=NLIST)
END
```

During execution, if a blank followed by ? is entered on a terminal device, the following values are displayed:

```
&NLIST
 A
 B
 C
/```

If a blank followed by =? is entered, the following values are displayed:

```
&NLIST
 A = 1.500000,
 B = 2,
 C = ABCDE
/```

**Examples**

Suppose the following statements are specified:

```fortran
NAMELIST /CONTROL/ TITLE, RESET, START, STOP, INTERVAL
CHARACTER*10 TITLE
REAL(KIND=8) START, STOP
LOGICAL(KIND=4) RESET
INTEGER(KIND=4) INTERVAL
READ (UNIT=1, NML=CONTROL)
```

2007
The NAMELIST statement associates the group name CONTROL with a list of five objects. The corresponding READ statement reads the following input data from unit 1:

```
&CONTROL
    TITLE='TESTT002AA',
    INTERVAL=1,
    RESET=.TRUE.,
    START=10.2,
    STOP =14.5
/
```

The following values are assigned to objects in group CONTROL:

<table>
<thead>
<tr>
<th>Namelist Object</th>
<th>Value Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>TITLE</td>
<td>TESTT002AA</td>
</tr>
<tr>
<td>RESET</td>
<td>T</td>
</tr>
<tr>
<td>START</td>
<td>10.2</td>
</tr>
<tr>
<td>STOP</td>
<td>14.5</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>1</td>
</tr>
</tbody>
</table>

It is not necessary to assign values to all of the objects declared in the corresponding NAMELIST group. If a namelist object does not appear in the input statement, its value (if any) is unchanged. Similarly, when character substrings and array elements are specified, only the values of the specified variable substrings and array elements are changed. For example, suppose the following input is read:

```
&CONTROL TITLE(9:10)='BB' /
```

The new value for TITLE is TESTT002BB; only the last two characters in the variable change.

The following example shows an array as an object:

```
DIMENSION ARRAY_A(20)
NAMELIST /ELEM/ ARRAY_A
READ (UNIT=1,NML=ELEM)
```
Suppose the following input is read:

\%ELEM

ARRAY_A=1.1, 1.2,, 1.4
/

The following values are assigned to the ARRAY_A elements:

<table>
<thead>
<tr>
<th>Array Element</th>
<th>Value Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARRAY_A(1)</td>
<td>1.1</td>
</tr>
<tr>
<td>ARRAY_A(2)</td>
<td>1.2</td>
</tr>
<tr>
<td>ARRAY_A(3)</td>
<td>Unchanged</td>
</tr>
<tr>
<td>ARRAY_A(4)</td>
<td>1.4</td>
</tr>
<tr>
<td>ARRAY_A(5)...ARRAY(20)</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>

When a list of values is assigned to an array element, the assignment begins with the specified array element, rather than with the first element of the array. For example, suppose the following input is read:

\%ELEM

ARRAY_A(3)=34.54, 45.34, 87.63, 3*20.00
/

New values are assigned only to array ARRAY_A elements 3 through 8. The other element values are unchanged.
The following shows another example:

```fortran
INTEGER a, b
NAMELIST /mynml/ a, b
...
! The following are all valid namelist variable assignments:
&mynml a = 1 /
$mynml a = 1$
$mynml a = 1$end
&mynml a = 1 $END
&mynml
a = 1
b = 2
/
```

Nondelimited character strings that are written out by using a NAMELIST write may not be read in as expected by a corresponding NAMELIST read. Consider the following:

```fortran
NAMELIST/TEST/ CHARR
CHARACTER*3 CHARR(4)
DATA CHARR/'AAA', 'BBB', 'CCC', 'DDD'/
OPEN (UNIT=1, FILE='NMLTEST.DAT')
WRITE (1, NML=TEST)
END
```

The output file NMLTEST.DAT will contain:

```fortran
&TESTCHARR = AAABBBCCCD/
If an attempt is then made to read the data in NMLTEST.DAT with a NAMELIST read using nondelimited character strings, as follows:

```fortran
NAMELIST/TEST/ CHARR
CHARACTER*3 CHARR(4)
DATA CHARR/4*' '/
OPEN (UNIT=1, FILE='NMLTEST.DAT')
READ (1, NML=TEST)
PRINT *, 'CHARR read in >', CHARR(1), '< >', CHARR(2), '< >',
1 CHARR(3), '< >', CHARR(4), '<'
END
```

The result is the following:

```
CHARR read in >AAA< > < > < > <
```

- NAMELIST
- Rules for Formatted Sequential READ Statements
- Alternative Form for Namelist External Records
- Rules for Namelist Sequential WRITE Statements

**Rules for Unformatted Sequential READ Statements**

Unformatted, sequential READ statements transfer binary data (without translation) between the current record and the entities specified in the I/O list. Only one record is read.

Objects of intrinsic or derived types can be transferred.

For data transfer, the file must be positioned so that the record read is an unformatted record or an end-of-file record.

The unformatted, sequential READ statement reads a single record. Each value in the record must be of the same type as the corresponding entity in the input list, unless the value is real or complex.

If the value is real or complex, one complex value can correspond to two real list entities, or two real values can correspond to one complex list entity. The corresponding values and entities must have the same kind parameter.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields. If the number of I/O list items is greater than the number of fields in an input record, an error occurs.
If a statement contains no I/O list, it skips over one full record, positioning the file to read the following record on the next execution of a READ statement.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

**Examples**

The following example shows an unformatted, sequential READ statement:

```fortran
READ (UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

**See Also**

- Forms for Sequential READ Statements
- READ statement
- Forms for Sequential READ Statements

**Forms for Direct-Access READ Statements**

Direct-access READ statements transfer input data from external records with direct access. (The attributes of a direct-access file are established by the OPEN statement.)

A direct-access READ statement can be formatted or unformatted, and takes one of the following forms:

**Formatted:**

```fortran
READ (eunit, format [, asynchronous] [, id] [, pos] [, iostat] [, err]) [io-list]
```

**Unformatted:**

```fortran
READ (eunit, rec [, asynchronous] [, id] [, pos] [, iostat] [, err]) [io-list]
```

---

2012
Building Applications for details on file sharing

Rules for Formatted Direct-Access READ Statements

Formatted, direct-access READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

For data transfer, the file must be positioned so that the record read is a formatted record or an end-of-file record.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is greater than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains. If more characters are required and nonadvancing input is in effect, an end-of-record condition occurs.

If the format specification specifies another record, the record number is increased by one as each subsequent record is read by that input statement.

Examples

The following example shows a formatted, direct-access READ statement:

```
READ (2, REC=35, FMT=10) (NUM(K), K=1,10)
```

Rules for Unformatted Direct-Access READ Statements

Unformatted, direct-access READ statements transfer binary data (without translation) between the current record and the entities specified in the I/O list. Only one record is read.

Objects of intrinsic or derived types can be transferred.

For data transfer, the file must be positioned so that the record read is an unformatted record or an end-of-file record.

The unformatted, direct-access READ statement reads a single record. Each value in the record must be of the same type as the corresponding entity in the input list, unless the value is real or complex.

If the value is real or complex, one complex value can correspond to two real list entities, or two real values can correspond to one complex list entity. The corresponding values and entities must have the same kind parameter.
If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields. If the number of I/O list items is greater than the number of fields in an input record, an error occurs.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

**Examples**

The following example shows unformatted, direct-access READ statements:

```fortran
READ (1, REC=10) LIST(1), LIST(8)
READ (4, REC=58, IOSTAT=K, ERR=500) (RHO(N), N=1,5)
```

**Forms for Stream READ Statements**

The forms for stream READ statements take the same forms as sequential READ statements. A POS specifier may be present to specify at what file position the READ will start.

You can impose a record structure on a formatted, sequential stream by using a new-line character as a record terminator (see intrinsic function NEW_LINE). There is no record structure in an unformatted, sequential stream.

The INQUIRE statement can be used with the POS specifier to determine the current file position in a stream file.

**Examples**

The following example shows stream READ statements:

```fortran
READ (12 ) I !stream reading without POS= specifier
READ (12,POS=10) J !stream reading with POS= specifier
```

**See Also**

- **READ Statements Overview**
- **NEW_LINE**

**Forms and Rules for Internal READ Statements**

Internal READ statements transfer input data from an internal file.

An internal READ statement can only be formatted. It must include format specifiers (which can use list-directed formatting). Namelist formatting is not permitted.

An internal READ statement takes the following form:

```fortran
READ (iunit, format [, iostat] [, err] [, end]) [io-list]
```
For more information on syntax, see READ.

Formatted, internal READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

This form of READ statement behaves as if the format begins with a BN edit descriptor. (You can override this behavior by explicitly specifying the BZ edit descriptor.)

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

Before data transfer occurs, the file is positioned at the beginning of the first record. This record becomes the current record.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is greater than the number of fields in an input record, the input record is padded with blanks. However, if PAD=’NO’ was specified for file connection, the input list and file specification must not require more characters from the record than it contains.

In list-directed formatting, character strings have no delimiters.
Examples

The following program segment reads a record and examines the first character to determine whether the remaining data should be interpreted as decimal, octal, or hexadecimal. It then uses internal READ statements to make appropriate conversions from character string representations to binary.

```fortran
INTEGER IVAL
CHARACTER TYPE, RECORD*80
CHARACTER*(*) AFMT, IFMT, OFMT, ZFMT
PARAMETER (AFMT='(Q,A)', IFMT= '(I10)', OFMT= '(O11)', & ZFMT= '(Z8)')
ACCEPT AFMT, ILEN, RECORD
TYPE = RECORD(1:1)
IF (TYPE .EQ. 'D') THEN
   READ (RECORD(2:MIN(ILEN, 11)), IFMT) IVAL
ELSE IF (TYPE .EQ. 'O') THEN
   READ (RECORD(2:MIN(ILEN, 12)), OFMT) IVAL
ELSE IF (TYPE .EQ. 'X') THEN
   READ (RECORD(2:MIN(ILEN, 9)),ZFMT) IVAL
ELSE
   PRINT *, 'ERROR'
END IF
END
```

- I/O lists
- Rules for List-Directed Sequential READ Statements

Building Applications for details on using internal files
ACCEPT Statement Overview

The ACCEPT statement is a data transfer input statement. This statement is the same as a formatted, sequential READ statement, except that an ACCEPT statement must never be connected to user-specified I/O units. You can override this restriction by using an environment variable. For more information, see Building Applications: Logical Devices.

WRITE Statements Overview

The WRITE statement is a data transfer output statement. Data can be output to external sequential or direct-access records, or to internal records. For more information, see WRITE.

See Also
• Data Transfer I/O Statements
• Forms for Sequential WRITE Statements
• Forms for Direct-Access WRITE Statements
• Forms for Stream WRITE Statements
• Forms and Rules for Internal WRITE Statements
• Forms for Sequential WRITE Statements
• Forms for Direct-Access WRITE Statements
• Forms for STREAM WRITE Statements
• Forms and Rules for Internal WRITE Statements

Forms for Sequential WRITE Statements

Sequential WRITE statements transfer output data to external sequential access records. The statements can be formatted by using format specifiers (which can use list-directed formatting) or namelist specifiers (for namelist formatting), or they can be unformatted.

A sequential WRITE statement takes one of the following forms:

**Formatted:**

```
```

**Formatted - List-Directed:**

```
```
Formatted - Namelist:
WRITE (eunit, nml-group [, asynchronous] [, id] [, pos] [, iostat] [, err])

Unformatted:

- Rules for Formatted Sequential WRITE Statements
- Rules for List-Directed Sequential WRITE Statements
- Rules for Namelist Sequential WRITE Statements
- Rules for Unformatted Sequential WRITE Statements
- I/O control-list specifiers
- I/O lists

Rules for Formatted Sequential WRITE Statements
Formatted, sequential WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for sequential access.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

The output list and format specification must not specify more characters for a record than the record size. (Record size is specified by RECL in an OPEN statement.)

If the file is connected for unformatted I/O, formatted data transfer is prohibited.

Examples
The following example shows formatted, sequential WRITE statements:
WRITE (UNIT=8, FMT='(B)', ADVANCE='NO') C
WRITE (*, '(F6.5)', ERR=25, IOSTAT=IO_STATUS) A, B, C
See Also
- Forms for Sequential WRITE Statements
- WRITE statement
- Forms for Sequential WRITE Statements

Rules for List-Directed Sequential WRITE Statements

List-directed, sequential WRITE statements transfer data from binary to character form by using the data types of the corresponding I/O list item to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input.

The following table shows the default output formats for each intrinsic data type:

### Table 610: Default Formats for List-Directed Output

<table>

</tbody>
</table>
By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.

A literal character constant or complex constant can be longer than an entire record. For complex constants, the end of the record can occur between the comma and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record. For literal constants that are longer than an entire record, the constant is continued onto as many records as necessary.

Each output record begins with a blank character for carriage control.

Slashes, octal values, null values, and repeated forms of values are not output.

If the file is connected for unformatted I/O, list-directed data transfer is prohibited.

**Examples**

Suppose the following statements are specified:

```fortran
DIMENSION A(4)
DATA A/4*3.4/
WRITE (1,*) 'ARRAY VALUES FOLLOW'
WRITE (1,*) A,4
```
The following records are then written to external unit 1:

```fortran
ARRAY VALUES FOLLOW
  3.400000  3.400000  3.400000  3.400000  4
```

The following shows another example:

```fortran
INTEGER i, j
REAL a, b
LOGICAL on, off
CHARACTER(20) c
DATA i /123456/, j /500/, a /28.22/, b /.0015555/
DATA on /.TRUE./, off/.FALSE./
DATA c /'Here''s a string'/
WRITE (*, *) i, j
WRITE (*, *) a, b, on, off
WRITE (*, *) c
END
```

The preceding example produces the following output:

```
123456 500
28.22000 1.555500E-03 T F
Here's a string
```

See Also
- Forms for Sequential WRITE Statements
- Rules for Formatted Sequential WRITE Statements
- Rules for List-Directed Sequential READ Statements

Rules for Namelist Sequential WRITE Statements

Namelist, sequential WRITE statements translate data from internal to external form by using the data types of the objects in the corresponding NAMELIST statement to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input. By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.
This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.

A literal character constant or complex constant can be longer than an entire record. In the case of complex constants, the end of the record can occur between the comma and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record.

Each output record begins with a blank character for carriage control, except for literal character constants that are continued from the previous record.

Slashes, octal values, null values, and repeated forms of values are not output.

If the file is connected for unformatted I/O, namelist data transfer is prohibited.

**Examples**

Consider the following statements:

```
CHARACTER*19 NAME(2)/2*' '/
REAL PITCH, ROLL, YAW, POSITION(3)
LOGICAL DIAGNOSTICS
INTEGER ITERATIONS
NAMELIST /PARAM/ NAME, PITCH, ROLL, YAW, POSITION, &
    DIAGNOSTICS, ITERATIONS
... READ (UNIT=1,NML=PARAM)
WRITE (UNIT=2,NML=PARAM)
```
Suppose the following input is read:

```
&PARAM
   NAME(2)(10:)= 'HEISENBERG',
   PITCH=5.0, YAW=0.0, ROLL=5.0,
   DIAGNOSTICS=.TRUE.,
   ITERATIONS=10
/
```

The following is then written to the file connected to unit 2:

```
&PARAM
NAME = ' ', ' ', 'HEISENBERG',
PITCH = 5.000000,
ROLL = 5.000000,
YAW = 0.0000000E+00,
POSITION = 3*0.0000000E+00,
DIAGNOSTICS = T,
ITERATIONS = 10
/
```

Note that character values are not enclosed in apostrophes unless the output file is opened with DELIM='APOSTROPHE'. The value of POSITION is not defined in the namelist input, so the current value of POSITION is written.
The following example declares a number of variables, which are placed in a namelist, initialized, and then written to the screen with namelist I/O:

```fortran
INTEGER(1) int1
INTEGER int2, int3, array(3)
LOGICAL(1) log1
LOGICAL log2, log3
REAL real1
REAL(8) real2
COMPLEX z1, z2
CHARACTER(1) char1
CHARACTER(10) char2
NAMELIST /example/ int1, int2, int3, log1, log2, log3, &
    real1, real2, z1, z2, char1, char2, array
int1  = 11
int2  = 12
int3  = 14
log1  = .TRUE.
log2  = .TRUE.
log3  = .TRUE.
real1 = 24.0
real2 = 28.0d0
z1    = (38.0,0.0)
z2    = (316.0d0,0.0d0)
char1 = 'A'
char2 = '0123456789'
array(1) = 41
array(2) = 42
array(3) = 43
WRITE (*, example)
```
The preceding example produces the following output:

```fortran
&EXAMPLE
INT1 = 11,
INT2 = 12,
INT3 = 14,
LOG1 = T,
LOG2 = T,
LOG3 = T,
REAL1 = 24.00000,
REAL2 = 28.0000000000000,
Z1 = (38.00000,0.0000000E+00),
Z2 = (316.0000,0.0000000E+00),
CHAR1 = A,
CHAR2 = 0123456789,
ARRAY = 41, 42, 43
/```

Rules for Unformatted Sequential WRITE Statements

Unformatted, sequential WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written.

Objects of intrinsic or derived types can be transferred.

This form of WRITE statement writes exactly one record. If there is no I/O item list, the statement writes one null record.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.
Examples

The following example shows an unformatted, sequential WRITE statement:

```fortran
WRITE (UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

Forms for Direct-Access WRITE Statements

Direct-access WRITE statements transfer output data to external records with direct access. (The attributes of a direct-access file are established by the OPEN statement.) A direct-access WRITE statement can be formatted or unformatted, and takes one of the following forms:

**Formatted:**

```fortran
WRITE (eunit, format, rec [, asynchronous] [, id] [, pos] [, iostat] [, err]) [io-list]
```

**Unformatted:**

```fortran
WRITE (eunit, rec [, asynchronous] [, id] [, pos] [, iostat] [, err]) [io-list]
```

- Rules for Unformatted Direct-Access WRITE Statements
- WRITE
- Rules for Formatted Direct-Access WRITE Statements
- Rules for Unformatted Direct-Access WRITE Statements
- I/O control-list specifiers
- I/O lists

Rules for Formatted Direct-Access WRITE Statements

Formatted, direct-access WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for direct access.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.
If the format specification specifies another record, the record number is increased by one as each subsequent record is written by that output statement.

**Examples**

The following example shows a formatted, direct-access WRITE statement:

```
WRITE (2, REC=35, FMT=10) (NUM(K), K=1,10)
```

**Rules for Unformatted Direct-Access WRITE Statements**

Unformatted, direct-access WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written. Objects of intrinsic or derived types can be transferred.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

**Examples**

The following example shows unformatted, direct-access WRITE statements:

```
WRITE (1, REC=10) LIST(1), LIST(8)
WRITE (4, REC=58, IOSTAT=K, ERR=500) (RHO(N), N=1,5)
```

**Forms for Stream WRITE Statements**

The forms for stream WRITE statements take the same forms as sequential WRITE statements. A POS specifier may be present to specify at what file position the WRITE will start.

You can impose a record structure on a formatted, sequential stream by using a new-line character as a record terminator (see intrinsic function NEW_LINE). There is no record structure in an unformatted, sequential stream.

The INQUIRE statement can be used with the POS specifier to determine the current file position in a stream file.

**See Also**

- WRITE Statements Overview
- NEW_LINE

**Forms and Rules for Internal WRITE Statements**

Internal WRITE statements transfer output data to an internal file.
An internal WRITE statement can only be formatted. It must include format specifiers (which can use list-directed formatting). Namelist formatting is not permitted.

An internal WRITE statement takes the following form:

\[ \text{WRITE} \left( \text{iunit}, \text{format} \left[, \text{iostat} \right] \right) \left[, \text{err} \right] \left[\text{io-list} \right] \]

For more information on syntax, see WRITE.

Formatted, internal WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an internal file.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the number of characters written in a record is less than the length of the record, the rest of the record is filled with blanks. The number of characters to be written must not exceed the length of the record.

Character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

**Examples**

The following example shows an internal WRITE statement:

```fortran
INTEGER J, K, STAT_VALUE
CHARACTER*50 CHAR_50
...
WRITE (FMT=*, UNIT=CHAR_50, IOSTAT=STAT_VALUE) J, K
```

*Building Applications* for details on using internal files

**PRINT and TYPE Statements Overview**

The PRINT statement is a data transfer output statement. TYPE is a synonym for PRINT. All forms and rules for the PRINT statement also apply to the TYPE statement.
The PRINT statement is the same as a formatted, sequential WRITE statement, except that the PRINT statement must never transfer data to user-specified I/O units. You can override this restriction by using an environment variable. For more information, see Building Applications: Logical Devices.

**REWRITE Statement Overview**

The REWRITE statement is a data transfer output statement that rewrites the current record. A REWRITE statement can be formatted or unformatted. For more information, see REWRITE in the *A to Z Reference*. 
A format appearing in an input or output (I/O) statement specifies the form of data being transferred and the data conversion (editing) required to achieve that form. The format specified can be explicit or implicit.

Explicit format is indicated in a format specification that appears in a FORMAT statement or a character expression (the expression must evaluate to a valid format specification).

The format specification contains edit descriptors, which can be data edit descriptors, control edit descriptors, or string edit descriptors.

Implicit format is determined by the processor and is specified using list-directed or namelist formatting. List-directed formatting is specified with an asterisk (*); namelist formatting is specified with a namelist group name.

List-directed formatting can be specified for advancing sequential files and internal files. Namelist formatting can be specified only for advancing sequential files.

This chapter contains information on the following topics:

- Format specifications
- Data edit descriptors
- Control edit descriptors
- Character string edit descriptors
- Nested and group repeat specifications
- Variable Format Expressions
- Printing of formatted records
- Interaction between FORMAT statements and I/O lists

**Format Specifications**

A format specification can appear in a FORMAT statement or character expression. In a FORMAT statement, it is preceded by the keyword FORMAT. A format specification takes the following form:

\[
\text{format-list}
\]

\[
\text{format-list} \quad \text{is a list of one or more of the following edit descriptors, separated by commas or slashes (/):}
\]

Data edit descriptors: I, B, O, Z, F, E, EN, ES, D, G, L, and A
Control edit descriptors: \( T, TL, TR, X, S, SP, SS, BN, BZ, P, :, /, $, \backslash, \text{ and } Q \)

String edit descriptors: \( H, 'c', \text{ and } "c", \text{ where } c \text{ is a character constant} \)

A comma can be omitted in the following cases:

- Between a \( P \) edit descriptor and an immediately following \( F, E, EN, ES, D, \text{ or } G \) edit descriptor
- Before a slash (/) edit descriptor when the optional repeat specification is not present
- After a slash (/) edit descriptor
- Before or after a colon (:) edit descriptor

Edit descriptors can be nested and a repeat specification can precede data edit descriptors, the slash edit descriptor, or a parenthesized list of edit descriptors.

**Description**

A FORMAT statement must be labeled.

Named constants are not permitted in format specifications.

If the associated I/O statement contains an I/O list, the format specification must contain at least one data edit descriptor or the control edit descriptor \( Q \).

Blank characters can precede the initial left parenthesis, and additional blanks can appear anywhere within the format specification. These blanks have no meaning unless they are within a character string edit descriptor.

When a formatted input statement is executed, the setting of the \( \text{BLANK} \) specifier (for the relevant logical unit) determines the interpretation of blanks within the specification. If the \( BN \) or \( BZ \) edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks. (For more information on \( \text{BLANK} \) defaults, see \( \text{BLANK Specifier} \) in OPEN statements.)

For formatted input, use the comma as an external field separator. The comma terminates the input of fields (for noncharacter data types) that are shorter than the number of characters expected. It can also designate null (zero-length) fields.
The first character of a record transmitted to a line printer or terminal is typically used for carriage control; it is not printed. The first character of such a record should be a blank, 0, 1, $, +, or ASCII NUL. Any other character is treated as a blank.

A format specification cannot specify more output characters than the external record can contain. For example, a line printer record cannot contain more than 133 characters, including the carriage control character.

The following table summarizes the edit descriptors that can be used in format specifications.

**Table 612: Summary of Edit Descriptors**

<table>
<thead>

<td>'c'</td>
<td>Transfers the character literal constant (between the delimiters) to an output record.</td>
</tr>
</tbody>
</table>

1 These delimiters can also be quotation marks (".")

**Character Format Specifications**

In data transfer I/O statements, a format specifier ([FMT=]format) can be a character expression that is a character array, character array element, or character constant. This type of format is also called a run-time format because it can be constructed or altered during program execution.

The expression must evaluate to a character string whose leading part is a valid format specification (including the enclosing parentheses).
If the expression is a character array element, the format specification must be contained entirely within that element.

If the expression is a character array, the format specification can continue past the first element into subsequent consecutive elements.

If the expression is a character constant delimited by apostrophes, use two consecutive apostrophes ('' ) to represent an apostrophe character in the format specification; for example:
   PRINT "("NUM can't be a real number")"

Similarly, if the expression is a character constant delimited by quotation marks, use two consecutive quotation marks ("" ) to represent a quotation mark character in the format specification.

To avoid using consecutive apostrophes or quotation marks, you can put the character constant in an I/O list instead of a format specification, as follows:
   PRINT "(A)", "NUM can't be a real number"

The following shows another character format specification:
   WRITE (6, '(I12, I4, I12)') I, J, K
In the following example, the format specification changes with each iteration of the DO loop:

```fortran
SUBROUTINE PRINT(TABLE)
REAL TABLE(10,5)
CHARACTER*5 FORCHR(0:5), RPAR*1, FBIG, FMED, FSML
DATA FORCHR(0), RPAR /'(',')'/
DATA FBIG, FMED, FSML /'F8.2,','F9.4,','F9.6,'/
DO I=1,10
  DO J=1,5
    IF (TABLE(I,J) .GE. 100.) THEN
      FORCHR(J) = FBIG
    ELSE IF (TABLE(I,J) .GT. 0.1) THEN
      FORCHR(J) = FMED
    ELSE
      FORCHR(J) = FSML
    END IF
  END DO
  FORCHR(5)(5:5) = RPAR
  WRITE (6,FORCHR) (TABLE(I,J), J=1,5)
END DO
END
```

The DATA statement assigns a left parenthesis to character array element FORCHR(0), and (for later use) a right parenthesis and three F edit descriptors to character variables.

Next, the proper F edit descriptors are selected for inclusion in the format specification. The selection is based on the magnitude of the individual elements of array TABLE.

A right parenthesis is added to the format specification just before the WRITE statement uses it.
NOTE. Format specifications stored in arrays are recompiled at run time each time they are used. If a Hollerith or character run-time format is used in a READ statement to read data into the format itself, that data is not copied back into the original array, and the array is unavailable for subsequent use as a run-time format specification.

Examples

The following example shows a format specification:

```fortran
WRITE (*, 9000) int1, real1(3), char1
9000 FORMAT (i5, 3f4.5, a16)
! I5, 3F5.2, A16 is the format list.
```

In the following example, the integer-variable name MYFMT refers to the FORMAT statement 9000, as assigned just before the FORMAT statement.

```fortran
ASSIGN 9000 TO MYFMT
9000 FORMAT (i5, 3f4.5, a16)
! I5, 3F5.2, A16 is the format list.
WRITE (*, MYFMT) iolist
```

The following shows a format example using a character expression:

```fortran
WRITE (*, '(i5, 3f5.2, a16)') iolist
! I5, 3F4.5, A16 is the format list.
```

In the following example, the format list is put into an 80-character variable called MYLIST:

```fortran
CHARACTER(80) MYLIST
MYLIST = '(i5, 3f5.2, a16)'
WRITE (*, MYLIST) iolist
```

Consider the following two-dimensional array:

```
1 2 3
4 5 6
```

In this case, the elements are stored in memory in the order: 1, 4, 2, 5, 3, 6 as follows:

```fortran
CHARACTER(6) array(3)
DATA array / 'i5', ',3f5.2', ',a16)' /
WRITE (*, array) iolist
```
In the following example, the WRITE statement uses the character array element array(2) as the format specifier for data transfer:

```fortran
CHARACTER(80) array(5)
array(2) = '(I5, 3F5.2, A16)'
WRITE (*, array(2)) iolist
```

- Nested and group repeats
- Printing of formatted records

Data Edit Descriptors

A data edit descriptor causes the transfer or conversion of data to or from its internal representation.

The part of a record that is input or output and formatted with data edit descriptors (or character string edit descriptors) is called a field.

- Forms for Data Edit Descriptors
- General Rules for Numeric Editing
- Integer Editing
- Real and Complex Editing
Forms for Data Edit Descriptors

A data edit descriptor takes one of the following forms:

\[ r \]c
\[ r \]cw
\[ r \]cw.m
\[ r \]cw.d
\[ r \]cw.d\{Ee\}

- \( r \) is a repeat specification. The range of \( r \) is 1 through 2147483647 (\(2^{31}-1\)). If \( r \) is omitted, it is assumed to be 1.
- \( c \) is one of the following format codes: I, B, O, Z, F, E, EN, ES, D, G, L, or A.
- \( w \) is the total number of digits in the field (the field width). If omitted, the system applies default values (see Default Widths for Data Edit Descriptors). The range of \( w \) is 1 through 2147483647 (\(2^{31}-1\)) on Intel® 64 architecture and IA-64 architecture; 1 through 32767 (\(2^{15}-1\)) on IA-32 architecture. For I, B, O, Z, and F, the range can start at zero.
- \( m \) is the minimum number of digits that must be in the field (including leading zeros). The range of \( m \) is 0 through 32767 (\(2^{15}-1\)) on Intel® 64 architecture and IA-64 architecture; 0 through 255 (\(2^{8}-1\)) on IA-32 architecture.
- \( d \) is the number of digits to the right of the decimal point (the significant digits). The range of \( d \) is 0 through 32767 (\(2^{15}-1\)) on Intel® 64 architecture and IA-64 architecture; 0 through 255 (\(2^{8}-1\)) on IA-32 architecture.

The number of significant digits is affected if a scale factor is specified for the data edit descriptor.

- \( E \) identifies an exponent field.
- \( e \) is the number of digits in the exponent. The range of \( e \) is 1 through 32767 (\(2^{15}-1\)) on Intel® 64 architecture and IA-64 architecture; 1 through 255 (\(2^{8}-1\)) on IA-32 architecture.
Description

Fortran 95/90 (and the previous standard) allows the field width to be omitted only for the A descriptor. However, Intel® Fortran allows the field width to be omitted for any data edit descriptor.

The $r$, $w$, $m$, $d$, and $e$ must all be positive, unsigned, integer literal constants; or variable format expressions -- no kind parameter can be specified. They must not be named constants.

Actual useful ranges for $r$, $w$, $m$, $d$, and $e$ may be constrained by record sizes (RECL) and the file system.

The data edit descriptors have the following specific forms:

<table>
<thead>
<tr>
<th>Type</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>Iw.[m], Bw.[m], Ow.[m], and Zw.[m]</td>
</tr>
<tr>
<td>Real and complex</td>
<td>Fw.d, Ew.d[Ee], ENw.d[Ee], ESw.d[Ee], Dw.d, and Gw.d[Ee]</td>
</tr>
<tr>
<td>Logical</td>
<td>Lw</td>
</tr>
<tr>
<td>Character</td>
<td>A[w]</td>
</tr>
</tbody>
</table>

The $d$ must be specified with F, E, D, and G field descriptors even if $d$ is zero. The decimal point is also required. You must specify both $w$ and $d$, or omit them both.

A repeat specification can simplify formatting. For example, the following two statements are equivalent:

```
20  FORMAT (E12.4,E12.4,E12.4,I5,I5,I5,I5)
20  FORMAT (3E12.4,4I5)
```
Examples

This WRITE outputs three integers, each in a five-space field and four reals in pairs of F7.2 and F5.2 values.

 INTEGER(2) int1, int2, int3
 REAL(4) r1, r2, r3, r4
 DATA int1, int2, int3 /143, 62, 999/
 DATA r1, r2, r3, r4 /2458.32, 43.78, 664.55, 73.8/
 WRITE (*,9000) int1, int2, int3, r1, r2, r3, r4

The following output is produced:

143 62 999 2458.32 43.78 664.55 73.80

• Nested and group repeats

General Rules for Numeric Editing

The following rules apply to input and output data for numeric editing (data edit descriptors I, B, O, Z, F, E, EN, ES, D, and G).

Rules for Input Processing

Leading blanks in the external field are ignored. If BLANK='NULL' is in effect (or the BN edit descriptor has been specified) embedded and trailing blanks are ignored; otherwise, they are treated as zeros. An all-blank field is treated as a value of zero.

The following table shows how blanks are interpreted by default:

<table>
<thead>
<tr>
<th>Type of Unit or File</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>An explicitly OPENed unit</td>
<td>BLANK='NULL'</td>
</tr>
<tr>
<td>An internal file</td>
<td>BLANK='NULL'</td>
</tr>
<tr>
<td>A preconnected file</td>
<td>BLANK='NULL'</td>
</tr>
</tbody>
</table>

1
For interactive input from preconnected files, you should explicitly specify the BN or BZ edit descriptor to ensure desired behavior.

A minus sign must precede a negative value in an external field; a plus sign is optional before a positive value.

In input records, constants can include any valid kind parameter. Named constants are not permitted.

If the data field in a record contains fewer than \( w \) characters, an input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data. The comma terminates the data field, and can also be used to designate null (zero-length) fields. For more information, see Terminating Short Fields of Input Data.

**Rules for Output Processing**

The field width \( w \) must be large enough to include any leading plus or minus sign, and any decimal point or exponent. For example, the field width for an E data edit descriptor must be large enough to contain the following:

- For positive numbers: \( d + 5 \) or \( d + e + 3 \) characters
- For negative numbers: \( d + 6 \) or \( d + e + 4 \) characters

A positive or zero value (zero is allowed for I, B, O, Z, and F descriptors) can have a plus sign, depending on which sign edit descriptor is in effect. If a value is negative, the leftmost nonblank character is a minus sign.

If the value is smaller than the field width specified, leading blanks are inserted (the value is right-justified). If the value is too large for the field width specified, the entire output field is filled with asterisks (*).

When the value of the field width is zero, the compiler selects the smallest possible positive actual field width that does not result in the field being filled with asterisks.

Compiler Options for details on compiler options

Integer Editing

Integer editing is controlled by the I (decimal), B (binary), O (octal), and Z (hexadecimal) data edit descriptors.

I Editing

The I edit descriptor transfers decimal integer values. It takes the following form:

\[ I^w[m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width). The \( m \) has no effect on input, only output.

The specified I/O list item must be of type integer or logical.

The G edit descriptor can be used to edit integer data; it follows the same rules as I^w.

Rules for Input Processing

On input, the I data edit descriptor transfers \( w \) characters from an external field and assigns their integer value to the corresponding I/O list item. The external field data must be an integer constant.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>I4</td>
<td>2788</td>
<td>2788</td>
</tr>
<tr>
<td>I3</td>
<td>-26</td>
<td>-26</td>
</tr>
<tr>
<td>I9</td>
<td>^^^^312</td>
<td>312</td>
</tr>
</tbody>
</table>

Rules for Output Processing

On output, the I data edit descriptor transfers the value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by a sign (a plus sign is optional for positive values, a minus sign is required for negative values), followed by an unsigned integer constant with no leading zeros.
If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>I3</td>
<td>284</td>
<td>284</td>

- Forms for data edit descriptors
- General rules for numeric editing

**B Editing**

The B data edit descriptor transfers binary (base 2) values. It takes the following form:

\[ \text{Bw}[.m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width). The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.
**Rules for Input Processing**

On input, the B data edit descriptor transfers \( w \) characters from an external field and assigns their binary value to the corresponding I/O list item. The external field must contain only binary digits (0 or 1) or blanks.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the B edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>B4</td>
<td>1001</td>
<td>9</td>
</tr>
<tr>
<td>B1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>B2</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the B data edit descriptor transfers the binary value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of binary digits) with no leading zeros. A negative value is transferred in internal form.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the B edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>B4</td>
<td>9</td>
<td>1001</td>
</tr>
<tr>
<td>B2</td>
<td>0</td>
<td>^0</td>
</tr>
</tbody>
</table>

**See Also**

- Integer Editing

- General rules for numeric editing

**O Editing**

The O data edit descriptor transfers octal (base 8) values. It takes the following form:

\[ Ow[.m] \]
The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width). The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

**Rules for Input Processing**

On input, the O data edit descriptor transfers \( w \) characters from an external field and assigns their octal value to the corresponding I/O list item. The external field must contain only octal digits (0 through 7) or blanks.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the O edit descriptor (the symbol \(^\) represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>05</td>
<td>32767</td>
<td>32767</td>
</tr>
<tr>
<td>04</td>
<td>16234</td>
<td>1623</td>
</tr>
<tr>
<td>03</td>
<td>97^</td>
<td>An error; the 9 is invalid in octal notation</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the O data edit descriptor transfers the octal value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of octal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.
The following shows output using the O edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>06</td>
<td>32767</td>
<td>^77777</td>
</tr>
<tr>

- General rules for numeric editing

**Z Editing**

The Z data edit descriptor transfers hexadecimal (base 16) values. It takes the following form:

\[ Zw[m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width). The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

**Rules for Input Processing**

On input, the Z data edit descriptor transfers \( w \) characters from an external field and assigns their hexadecimal value to the corresponding I/O list item. The external field must contain only hexadecimal digits (0 through 9 and A (a) through F(f)) or blanks.

If the value exceeds the range of the corresponding input list item, an error occurs.
The following shows input using the Z edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Z3</td>
<td>A94</td>
<td>A94</td>

<tr>
<td>Z5</td>
<td>A23DEF</td>
<td>A23DE</td>
</tr>
<tr>
<td>Z5</td>
<td>95.AF2</td>
<td>An error; the decimal point is invalid</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the Z data edit descriptor transfers the hexadecimal value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of hexadecimal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the Z edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Z4</td>
<td>32767</td>
<td>7FFF</td>
</tr>

<tr>
<td>Z6.4</td>
<td>2708</td>
<td>^^0A94</td>
</tr>
</tbody>
</table>

**See Also**

- Integer Editing
- Forms for data edit descriptors
- General rules for numeric editing

**Real and Complex Editing**

Real and complex editing is controlled by the F, E, D, EN, ES, and G data edit descriptors.
If no field width ($w$) is specified for a real data edit descriptor, the system supplies default values. Real data edit descriptors can be affected by specified scale factors.

**NOTE.** Do not use the real data edit descriptors when attempting to parse textual input. These descriptors accept some forms that are purely textual as valid numeric input values. For example, input values T and F are treated as values -1.0 and 0.0, respectively, for .TRUE. and .FALSE.

**F Editing**

The F data edit descriptor transfers real values. It takes the following form:  
\[ Fw.d \]

The value of $d$ (the number of places after the decimal point) must not exceed the value of $w$ (the field width).

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

**Rules for Input Processing**

On input, the F data edit descriptor transfers $w$ characters from an external field and assigns their real value to the corresponding I/O list item. The external field data must be an integer or real constant.

If the input field contains only an exponent letter or decimal point, it is treated as a zero value.

If the input field does not contain a decimal point or an exponent, it is treated as a real number of $w$ digits, with $d$ digits to the right of the decimal point. (Leading zeros are added, if necessary.)

If the input field contains a decimal point, the location of that decimal point overrides the location specified by the F descriptor.

If the field contains an exponent, that exponent is used to establish the magnitude of the value before it is assigned to the list element.
The following shows input using the F edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5</td>
<td>123456789</td>
<td>123.45678</td>
</tr>
<tr>
<td>F8.5</td>
<td>-1234.567</td>
<td>-1234.56</td>
</tr>
<tr>
<td>F8.5</td>
<td>24.77E+2</td>
<td>2477.0</td>
</tr>
<tr>
<td>F5.2</td>
<td>1234567.89</td>
<td>123.45</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the F data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to \( d \) decimal positions, to an external field that is \( w \) characters long.

The \( w \) must be greater than or equal to \( d+3 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- At least one digit to the left of the decimal point
- The decimal point
- The \( d \) digits to the right of the decimal point

The following shows output using the F edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5</td>
<td>2.3547188</td>
<td>^2.35472</td>
</tr>
<tr>
<td>F9.3</td>

</tr>
<tr>
<td>F5.2</td>
<td>325.013</td>
<td>^^^^^^</td>
</tr>
<tr>
<td>F5.2</td>
<td>-.2</td>
<td>^-0.20</td>
</tr>
</tbody>
</table>

**See Also**

- Real and Complex Editing
- Forms for data edit descriptors
- General rules for numeric editing
E and D Editing

The E and D data edit descriptors transfer real values in exponential form. They take the following form:

$$Ew.d[\text{Ee}]$$

$$Dw.d$$

For the E edit descriptor, the value of \(d\) (the number of places after the decimal point) plus \(e\) (the number of digits in the exponent) must not exceed the value of \(w\) (the field width).

For the D edit descriptor, the value of \(d\) must not exceed the value of \(w\).

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the E and D data edit descriptors transfer \(w\) characters from an external field and assigns their real value to the corresponding I/O list item. The E and D descriptors interpret and assign input data in the same way as the F data edit descriptor.

The following shows input using the E and D edit descriptors (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>E9.3</td>
<td>734.432E3</td>
<td>734432.0</td>
</tr>
<tr>
<td>E12.4</td>
<td>^^1022.43E</td>
<td>1022.43E-6</td>
</tr>
<tr>
<td>E15.3</td>
<td>52.3759663^</td>
<td>52.3759663</td>
</tr>
<tr>
<td>E12.5</td>
<td>210.5271E10</td>
<td>210.5271E10</td>
</tr>
<tr>
<td>BZ,D10.2</td>
<td>12345^</td>
<td>12345000.0D0</td>
</tr>
<tr>
<td>D10.2</td>
<td>^^123.45^</td>
<td>123.45D0</td>
</tr>
<tr>
<td>D15.3</td>
<td>367.4981763D+04</td>
<td>3.674981763D+06</td>
</tr>
</tbody>
</table>

If the I/O list item is single-precision real, the E edit descriptor treats the D exponent indicator as an E indicator.

Rules for Output Processing

On output, the E and D data edit descriptors transfer the real value of the corresponding I/O list item, right-justified and rounded to \(d\) decimal positions, to an external field that is \(w\) characters long.
The \( \var{w} \) should be greater than or equal to \( \var{d} + 7 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- An optional zero to the left of the decimal point
- The decimal point
- The \( \var{d} \) digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ew.d</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(</td>
<td>\var{exp}</td>
<td>99 )</td>
<td>E+nn</td>
</tr>
<tr>
<td>( 99 &lt;</td>
<td>\var{exp}</td>
<td>999 )</td>
<td>+\var{nn}</td>
</tr>
<tr>
<td>Ew.dEe</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(</td>
<td>\var{exp}</td>
<td>10^\var{e} - 1 )</td>
<td>E+\var{n_1n_2...n_e}</td>
</tr>
<tr>
<td>Dw.d</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(</td>
<td>\var{exp}</td>
<td>99 )</td>
<td>D+\var{nn} or E+\var{nn}</td>
</tr>
<tr>
<td>( 99 &lt;</td>
<td>\var{exp}</td>
<td>999 )</td>
<td>+\var{nn}</td>
</tr>
</tbody>
</table>

If the exponent value is too large to be converted into one of these forms, an error occurs.

The exponent field width (\( \var{e} \)) is optional for the E edit descriptor; if omitted, the default value is 2. If \( \var{e} \) is specified, the \( \var{w} \) should be greater than or equal to \( \var{d} + \var{e} + 5 \).

**NOTE.** The \( \var{w} \) can be as small as \( \var{d} + 5 \) or \( \var{d} + \var{e} + 3 \), if the optional fields for the sign and the zero are omitted.
The following shows output using the E and D edit descriptors (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>

<td>**********</td>
</tr>
</tbody>
</table>

**See Also**

- Real and Complex Editing
- Forms for data edit descriptors
- General rules for numeric editing
- Scale Factor Editing (P)

**EN Editing**

The EN data edit descriptor transfers values by using engineering notation. It takes the following form:

ENw.d[Ee]

The value of $d$ (the number of places after the decimal point) plus $e$ (the number of digits in the exponent) must not exceed the value of $w$ (the field width).

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

**Rules for Input Processing**

On input, the EN data edit descriptor transfers $w$ characters from an external field and assigns their real value to the corresponding I/O list item. The EN descriptor interprets and assigns input data in the same way as the F data edit descriptor.
The following shows input using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN11.3</td>
<td>^^5.321E+00</td>
<td>5.32100</td>
</tr>
<tr>
<td>EN11.3</td>
<td>-600.00E-03</td>
<td>-.60000</td>
</tr>
<tr>
<td>EN12.3</td>
<td>^^3.150E-03</td>
<td>.00315</td>
</tr>
<tr>
<td>EN12.3</td>
<td>^^3.829E+03</td>
<td>3829.0</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the EN data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to \(d\) decimal positions, to an external field that is \(w\) characters long. The real value is output in engineering notation, where the decimal exponent is divisible by 3 and the absolute value of the significand is greater than or equal to 1 and less than 1000 (unless the output value is zero).

The \(w\) should be greater than or equal to \(d+9\) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One to three digits to the left of the decimal point
- The decimal point
- The \(d\) digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENw.d</td>
<td>(</td>
<td>\text{exp}</td>
<td>\ 99 )</td>
</tr>
<tr>
<td></td>
<td>(99 &lt;</td>
<td>\text{exp}</td>
<td>\ 999)</td>
</tr>
<tr>
<td>ENw.dEe</td>
<td>(</td>
<td>\text{exp}</td>
<td>\ 10^6 - 1)</td>
</tr>
</tbody>
</table>

If the exponent value is too large to be converted into one of these forms, an error occurs.

The exponent field width (\(e\)) is optional; if omitted, the default value is 2. If \(e\) is specified, the \(w\) should be greater than or equal to \(d + e + 5\).
The following shows output using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN11.2</td>
<td>475867.222</td>

- Forms for data edit descriptors
- General rules for numeric editing

ES Editing

The ES data edit descriptor transfers values by using scientific notation. It takes the following form:

ES\[d\][Ee]

The value of $d$ (the number of places after the decimal point) plus $e$ (the number of digits in the exponent) must not exceed the value of $w$ (the field width).

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the ES data edit descriptor transfers \[w\] characters from an external field and assigns their real value to the corresponding I/O list item. The ES descriptor interprets and assigns input data in the same way as the F data edit descriptor.
The following shows input using the ES edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ES11.3</td>
<td>^^5.321E+00</td>
<td>5.32100</td>
</tr>
<tr>
<td>ES11.3</td>
<td>~6.000E-03</td>
<td>-.60000</td>
</tr>
<tr>
<td>ES12.3</td>
<td>^^3.150E-03</td>
<td>.00315</td>
</tr>
<tr>
<td>ES12.3</td>
<td>^^3.829E+03</td>
<td>3829.0</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the ES data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to $d$ decimal positions, to an external field that is $w$ characters long. The real value is output in scientific notation, where the absolute value of the significand is greater than or equal to 1 and less than 10 (unless the output value is zero).

The $w$ should be greater than or equal to $d + 7$ to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One digit to the left of the decimal point
- The decimal point
- The $d$ digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESw.d</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>99</td>
<td></td>
<td>E+nn</td>
<td>E-nn</td>
</tr>
<tr>
<td>99 &lt;</td>
<td>exp</td>
<td>999</td>
<td>+nnn</td>
</tr>
<tr>
<td>ESw.dEe</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$10^e - 1$</td>
<td></td>
<td>E+n1n2...ne</td>
<td>E-n1n2...ne</td>
</tr>
</tbody>
</table>

If the exponent value is too large to be converted into one of these forms, an error occurs.

The exponent field width ($e$) is optional; if omitted, the default value is 2. If $e$ is specified, the $w$ should be greater than or equal to $d + e + 5$. 
The following shows output using the ES edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>ES11.2</td>
<td>473214.356</td>
<td>^^^4.73E+05</td>
</tr>
<tr>
<td>ES11.5</td>
<td>473214.356</td>
<td>4.73214E+05</td>
</tr>
<tr>
<td>ES12.3</td>
<td>0.00069</td>
<td>^^^6.900E-04</td>
</tr>
<tr>
<td>ES10.3</td>
<td>-0.5555</td>
<td>-5.555E-01</td>
</tr>
<tr>
<td>ES11.2</td>
<td>0.0</td>
<td>^0.000E+00</td>
</tr>
</tbody>
</table>

- General rules for numeric editing

G Editing

The G data edit descriptor generally transfers values of real type, but it can be used to transfer values of any intrinsic type. It takes the following form:

\[ G_w.d[Ee] \]

The value of \( d \) (the number of places after the decimal point) plus \( e \) (the number of digits in the exponent) must not exceed the value of \( w \) (the field width).

The specified I/O list item can be of any intrinsic type.

When used to specify I/O for integer, logical, or character data, the edit descriptor follows the same rules as \( I_w \), \( L_w \), and \( A_w \), respectively, and \( d \) and \( e \) have no effect.

Rules for Real Input Processing

On input, the G data edit descriptor transfers \( w \) characters from an external field and assigns their real value to the corresponding I/O list item. The G descriptor interprets and assigns input data in the same way as the F data edit descriptor.

Rules for Real Output Processing

On output, the G data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to \( d \) decimal positions, to an external field that is \( w \) characters long.

The form in which the value is written is a function of the magnitude of the value, as described in the following table:
<table>
<thead>
<tr>
<th>Data Magnitude</th>
<th>Effective Conversion</th>
</tr>
</thead>
<tbody>
<tr>
<td>$0 &lt; m &lt; 0.1 - 0.5 \times 10^{-d-1}$</td>
<td>Ew.d[Ee]</td>
</tr>
<tr>
<td>$m = 0$</td>
<td>F(w - n).(d -1), n('b')</td>
</tr>
<tr>
<td>$0.1 - 0.5 \times 10^{-d-1} m &lt; 1 - 0.5 \times 10^d$</td>
<td>F(w - n).d, n('b')</td>
</tr>
<tr>
<td>$1 - 0.5 \times 10^{-d} m &lt; 10 - 0.5 \times 10^{-d+1}$</td>
<td>F(w - n).(d -1), n('b')</td>
</tr>
<tr>
<td>$10 - 0.5 \times 10^{-d+1} m &lt; 100 - 0.5 \times 10^{-d+2}$</td>
<td>F(w - n).(d -2), n('b')</td>
</tr>
<tr>
<td>$\cdot$</td>
<td>$\cdot$</td>
</tr>
<tr>
<td>$\cdot$</td>
<td>$\cdot$</td>
</tr>
<tr>
<td>$\cdot$</td>
<td>$\cdot$</td>
</tr>
<tr>
<td>$10^{-d-2} - 0.5 \times 10^{-2} m &lt; 10^{-d-1} - 0.5 \times 10^{-1}$</td>
<td>F(w - n).1, n('b')</td>
</tr>
<tr>
<td>$10^{-d-1} - 0.5 \times 10^{-1} m &lt; 10^d - 0.5$</td>
<td>(w - n).0, n('b')</td>
</tr>
<tr>
<td>$m 10^d - 0.5$</td>
<td>Ew.d[Ee]</td>
</tr>
</tbody>
</table>

The 'b' is a blank following the numeric data representation. For Gw.d, n('b') is 4 blanks. For Gw.dEe, n('b') is $e+2$ blanks.

The $w$ should be greater than or equal to $d+7$ to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One digit to the left of the decimal point
- The decimal point
- The $d$ digits to the right of the decimal point
- The 4-digit or $e+2$-digit exponent

If $e$ is specified, the $w$ should be greater than or equal to $d + e + 5$. 
The following shows output using the G edit descriptor and compares it to output using equivalent F editing (the symbol ^ represents a nonprinting blank character):

<table>

- I data edit descriptor
- L data edit descriptor
- A data edit descriptor
- Scale Factor Editing (P)

**Complex Editing**

A complex value is an ordered pair of real values. Complex editing is specified by a pair of real edit descriptors, using any combination of the forms: Fw.d, Ew.d[Ee], Dw.d, ENw.d[Ee], ESw.d[Ee], or Gw.d[Ee].

**Rules for Input Processing**

On input, the two successive fields are read and assigned to the corresponding complex I/O list item as its real and imaginary part, respectively.
The following shows input using complex editing:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5,F8.5</td>
<td>1234567812345.67</td>
<td>123.45678, 12345.67</td>
</tr>
<tr>
<td>E9.1,F9.3</td>
<td>734.432E8123456789</td>
<td>734.432E8, 123456.789</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the two parts of the complex value are transferred under the control of repeated or successive real edit descriptors. The two parts are transferred consecutively without punctuation or blanks, unless control or character string edit descriptors are specified between the pair of real edit descriptors.

The following shows output using complex editing (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>2F8.5</td>
<td>2.3547188, 3.456732</td>
<td>^2.35472 ^3.45673</td>
</tr>
<tr>
<td>E9.2,'^','^',E5.3</td>
<td>47587.222, 56.123</td>
<td>^0.48E+06^,^*****</td>
</tr>
</tbody>
</table>

**See Also**
- Real and Complex Editing
- Forms for data edit descriptors
- General rules for numeric editing
- General Rules for Complex Constants

**Logical Editing (L)**

The L data edit descriptor transfers logical values. It takes the following form:

Lw

The specified I/O list item must be of type logical or integer.

The G edit descriptor can be used to edit logical data; it follows the same rules as Lw.

**Rules for Input Processing**

On input, the L data edit descriptor transfers w characters from an external field and assigns their logical value to the corresponding I/O list item. The value assigned depends on the external field data, as follows:
• .TRUE. is assigned if the first nonblank character is .T, T, .t, or t. The logical constant .TRUE. is an acceptable input form.
• .FALSE. is assigned if the first nonblank character is .F, F, .f, or f, or the entire field is filled with blanks. The logical constant .FALSE. is an acceptable input form.

If an other value appears in the external field, an error occurs.

### Rules for Output Processing

On output, the L data edit descriptor transfers the following to an external field that is \( w \) characters long: \( w - 1 \) blanks, followed by a T or F (if the value is .TRUE. or .FALSE., respectively).

The following shows output using the L edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>L5</td>
<td>.TRUE.</td>
<td>^^^^T</td>
</tr>
<tr>
<td>L1</td>
<td>.FALSE.</td>
<td>F</td>
</tr>
</tbody>
</table>

### See Also
- Data Edit Descriptors
- Forms for data edit descriptors

### Character Editing (A)

The A data edit descriptor transfers character or Hollerith values. It takes the following form:

\[ A[w] \]

If the corresponding I/O list item is of type character, character data is transferred. If the list item is of any other type, Hollerith data is transferred.

The G edit descriptor can be used to edit character data; it follows the same rules as A\(w\).

### Rules for Input Processing

On input, the A data edit descriptor transfers \( w \) characters from an external field and assigns them to the corresponding I/O list item.

The maximum number of characters that can be stored depends on the size of the I/O list item, as follows:
- For character data, the maximum size is the length of the corresponding I/O list item.
- For noncharacter data, the maximum size depends on the data type, as shown in the following table:

**Table 619: Size Limits for Noncharacter Data Using A Editing**

<table>
<thead>
<tr>
<th>I/O List Element</th>
<th>Maximum Number of Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(1) or LOGICAL*1</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(2) or LOGICAL*2</td>
<td>2</td>
</tr>
<tr>
<td>LOGICAL(4) or LOGICAL*4</td>
<td>4</td>
</tr>
<tr>
<td>LOGICAL(8) or LOGICAL*8</td>
<td>8</td>
</tr>
<tr>
<td>INTEGER(1) or INTEGER*1</td>
<td>1</td>
</tr>
<tr>
<td>INTEGER(2) or INTEGER*2</td>
<td>2</td>
</tr>
<tr>
<td>INTEGER(4) or INTEGER*4</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(8) or INTEGER*8</td>
<td>8</td>
</tr>
<tr>
<td>REAL(4) or REAL*4</td>
<td>4</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>8</td>
</tr>
<tr>
<td>REAL(8) or REAL*8</td>
<td>8</td>
</tr>
<tr>
<td>REAL(16) or REAL*16</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(4) or COMPLEX*8(^1)</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE COMPLEX(^1)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(8) or COMPLEX*16(^1)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(16) or COMPLEX*32(^1)</td>
<td>32</td>
</tr>
</tbody>
</table>
Complex values are treated as pairs of real numbers, so complex editing requires a pair of edit descriptors. (See Complex Editing.)

If \( w \) is equal to or greater than the length (\( \text{len} \)) of the input item, the rightmost characters are assigned to that item. The leftmost excess characters are ignored.

If \( w \) is less than \( \text{len} \), or less than the number of characters that can be stored, \( w \) characters are assigned to the list item, left-justified, and followed by trailing blanks.

The following shows input using the A edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input Value</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>A6</td>
<td>PAGE^# #</td>
<td>CHARACTER(LEN=1)</td>
</tr>
<tr>
<td>A6</td>
<td>PAGE^# E^#</td>
<td>CHARACTER(LEN=3)</td>
</tr>
<tr>
<td>A6</td>
<td>PAGE^# PAGE^#</td>
<td>CHARACTER(LEN=6)</td>
</tr>
<tr>
<td>A6</td>
<td>PAGE^# PAGE^#^^</td>
<td>CHARACTER(LEN=8)</td>
</tr>
<tr>
<td>A6</td>
<td>PAGE^# #</td>
<td>LOGICAL(1)</td>
</tr>
<tr>

<td>A6</td>
<td>PAGE^# GE^#</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>A6</td>
<td>PAGE^# PAGE^#^^</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the A data edit descriptor transfers the contents of the corresponding I/O list item to an external field that is \( w \) characters long.

If \( w \) is greater than the size of the list item, the data is transferred to the output field, right-justified, with leading blanks. If \( w \) is less than or equal to the size of the list item, the leftmost \( w \) characters are transferred.
The following shows output using the A edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>A5</td>

- [Forms for data edit descriptors](#)

**Default Widths for Data Edit Descriptors**

If \( w \) (the field width) is omitted for the data edit descriptors, the system applies default values. For the real data edit descriptors, the system also applies default values for \( d \) (the number of characters to the right of the decimal point), and \( e \) (the number of characters in the exponent).

These defaults are based on the data type of the I/O list item, and are listed in the following table:

**Table 620: Default Widths for Data Edit Descriptors**

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Data Type of I/O List Item</th>

</tbody>
</table>

\(^1\) The default is the actual length of the corresponding I/O list item.

**Terminating Short Fields of Input Data**

On input, an edit descriptor such as Fw.d specifies that \(w\) characters (the field width) are to be read from the external field.

If the field contains fewer than \(w\) characters, the input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data.
Padding Short Fields

You can use the OPEN statement specifier PAD='YES' to indicate blank padding for short fields of input data. However, blanks can be interpreted as blanks or zeros, depending on which default behavior is in effect at the time. Consider the following:

```
READ (2, '(I5)') J
```

If 3 is input for J, the value of J will be 30000 or 3 depending on which default behavior is in effect (BLANK='NULL' or BLANK='ZERO'). This can give unexpected results.

To ensure that the desired behavior is in effect, explicitly specify the BN or BZ edit descriptor. For example, the following ensures that blanks are interpreted as blanks (and not as zeros):

```
READ (2, '(BN, I5)') J
```

Using Commas to Separate Input Data

You can use a comma to terminate a short data field. The comma has no effect on the $d$ part (the number of characters to the right of the decimal point) of the specification.

The comma overrides the $w$ specified for the I, B, O, Z, F, E, D, EN, ES, G, and L edit descriptors. For example, suppose the following statements are executed:

```
READ (5,100) I,J,A,B
100 FORMAT (2I6,2F10.2)
```

Suppose a record containing the following values is read:

```
1, -2, 1.0, 35
```

The following assignments occur:

```
I = 1
J = -2
A = 1.0
B = 0.35
```

A comma can only terminate fields less than $w$ characters long. If a comma follows a field of $w$ or more characters, the comma is considered part of the next field.

A null (zero-length) field is designated by two successive commas, or by a comma after a field of $w$ characters. Depending on the field descriptor specified, the resulting value assigned is 0, 0.0, 0.0D0, 0.0Q0, or .FALSE..

• Dollar Sign ($) and Backslash (\) Editing
• Character Count Editing (Q)

Forms for Control Edit Descriptors
A control edit descriptor takes one of the following forms:

\[ c \]
\[ cn \]
\(nc\)

\(c\)

Is one of the following format codes: T, TL, TR, X, S, SP, SS, BN, BZ, P, ;, /, \, $, and Q.

\(n\)

Is a number of character positions. It must be a positive integer literal constant or a variable format expression. No kind parameter can be specified. It cannot be a named constant. The range of \(n\) is 1 through 2,147,483,647 (2**31-1) on Intel® 64 architecture and IA-64 architecture; 1 through 32,767 (2**15-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.

**Description**

In general, control edit descriptors are nonrepeatable. The only exception is the slash (/) edit descriptor, which can be preceded by a repeat specification.

The control edit descriptors have the following specific forms:

<table>
<thead>
<tr>
<th>Positional:</th>
<th>Tn, TLn, TRn, and nX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign:</td>
<td>S, SP, and SS</td>
</tr>
<tr>
<td>Blank interpretation:</td>
<td>BN and BZ</td>
</tr>
<tr>
<td>Scale factor:</td>
<td>kP</td>
</tr>
<tr>
<td>Miscellaneous:</td>
<td>;, /, , $, and Q</td>
</tr>
</tbody>
</table>

The P edit descriptor is an exception to the general control edit descriptor syntax. It is preceded by a scale factor, rather than a character position specifier.

Control edit descriptors can be grouped in parentheses and preceded by a group repeat specification.

**See Also**

- Control Edit Descriptors
- Group repeat specifications
- Format Specifications
**Positional Editing**

The T, TL, TR, and X edit descriptors specify the position where the next character is transferred to or from a record.

On output, these descriptors do not themselves cause characters to be transferred and do not affect the length of the record. If characters are transferred to positions at or after the position specified by one of these descriptors, positions skipped and not previously filled are filled with blanks. The result is as if the entire record was initially filled with blanks.

The TR and X edit descriptors produce the same results.

**T Editing**

The T edit descriptor specifies a character position in an I/O record. It takes the following form:

\[ Tn \]

The \( n \) is a positive integer literal constant (with no kind parameter) indicating the character position of the record, relative to the left tab limit.

On input, the T descriptor positions the external record at the character position specified by \( n \). On output, the T descriptor indicates that data transfer begins at the \( n \)th character position of the external record.

**Examples**

In the following examples, the symbol ^ represents a nonprinting blank character.

Suppose a file has a record containing the value `ABC^^^XYZ`, and the following statements are executed:

```fortran
READ (11,10) VALUE1, VALUE2
10 FORMAT (T7,A3,T1,A3)
```

The values read first are XYZ, then ABC.

Suppose the following statements are executed:

```fortran
PRINT 25
25 FORMAT (T51,'COLUMN 2',T21,'COLUMN 1')
```

The following line is printed at the positions indicated:

```
Position 20 | Position 50
| | |
COLUMN 1 | COLUMN 2
```

Note that the first character of the record printed was reserved as a control character.
See Also

• Positional Editing
• Printing of Formatted Records

TL Editing

The TL edit descriptor specifies a character position to the left of the current position in an I/O record. It takes the following form:

\( TL_n \)

The \( n \) is a positive integer literal constant (with no kind parameter) indicating the \( n \)th character position to the left of the current character.

If \( n \) is greater than or equal to the current position, the next character accessed is the first character of the record.

TR Editing

The TR edit descriptor specifies a character position to the right of the current position in an I/O record. It takes the following form:

\( TR_n \)

The \( n \) is a positive integer literal constant (with no kind parameter) indicating the \( n \)th character position to the right of the current character.

X Editing

The X edit descriptor specifies a character position to the right of the current position in an I/O record. It takes the following form:

\( nX \)

The \( n \) is a positive integer literal constant (with no kind parameter) indicating the \( n \)th character position to the right of the current character.

On output, the X edit descriptor does not output any characters when it appears at the end of a format specification; for example:

\[
\text{WRITE (6,99) K}
\]

\[
99 \quad \text{FORMAT ('^K=',I6,5X)}
\]

Note that the symbol \(^\) represents a nonprinting blank character. This example writes a record of only 9 characters. To cause \( n \) trailing blanks to be output at the end of a record, specify a format of \( n('^') \).

Sign Editing

The S, SP, and SS edit descriptors control the output of the optional plus (+) sign within numeric output fields. These descriptors have no effect during execution of input statements.

---

2071
Within a format specification, a sign editing descriptor affects all subsequent I, F, E, EN, ES, D, and G descriptors until another sign editing descriptor occurs.

**Examples**

```fortran
INTEGER i
REAL r
!
! The following statements write:
! 251 +251 251 +251 251
i = 251
WRITE (*, 100) i, i, i, i, i
100 FORMAT (I5, SP, I5, SS, I5, SP, I5, S, I5)
!
! The following statements write:
! 0.673E+4 +.673E+40.673E+4 +.673E+40.673E+4
r = 67.3E2
WRITE (*, 200) r, r, r, r, r
200 FORMAT (E8.3E1, 1X, SP, E8.3E1, SS, E8.3E1, 1X, SP, &
  & E8.3E1, S, E8.3E1)
```

**SP Editing**

The SP edit descriptor causes the processor to *produce* a plus sign in any subsequent position where it would be otherwise optional. It takes the following form:

```
SP
```

**SS Editing**

The SS edit descriptor causes the processor to *suppress* a plus sign in any subsequent position where it would be otherwise optional. It takes the following form:

```
SS
```

**S Editing**

The S edit descriptor restores the plus sign as optional for all subsequent positive numeric fields. It takes the following form:

```
S
```

The S edit descriptor restores to the processor the discretion of producing plus characters on an optional basis.
Blank Editing

The BN and BZ descriptors control the interpretation of embedded and trailing blanks within numeric input fields. These descriptors have no effect during execution of output statements.

Within a format specification, a blank editing descriptor affects all subsequent I, B, O, Z, F, E, EN, ES, D, and G descriptors until another blank editing descriptor occurs.

The blank editing descriptors override the effect of the BLANK specifier during execution of a particular input data transfer statement. (For more information, see the BLANK specifier in OPEN statements.)

BN Editing

The BN edit descriptor causes the processor to ignore all embedded and trailing blanks in numeric input fields. It takes the following form:

BN

The input field is treated as if all blanks have been removed and the remainder of the field is right-justified. An all-blank field is treated as zero.

Examples

If an input field formatted as a six-digit integer (I6) contains '2 3 4', it is interpreted as '234'.

Consider the following code:

```
READ (*, 100) n
100 FORMAT (BN, I6)
```

If you enter any one of the following three records and terminate by pressing Enter, the READ statement interprets that record as the value 123:

```
123
123
123 456
```

Because the repeatable edit descriptor associated with the I/O list item n is I6, only the first six characters of each record are read (three blanks followed by 123 for the first record, and 123 followed by three blanks for the last two records). Because blanks are ignored, all three records are interpreted as 123.

The following example shows the effect of BN editing with an input record that has fewer characters than the number of characters specified by the edit descriptors and iolist. Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. With BN editing in effect, the nonblank characters (123) are right-aligned, so the record is equal to 123.

**BZ Editing**

The BZ edit descriptor causes the processor to interpret all embedded and trailing blanks in numeric input fields as zeros. It takes the following form:

\[ \text{BZ} \]

**Examples**

The input field ' 23 4 ' would be interpreted as ' 23040 '. If ' 23 4 ' were entered, the formatter would add one blank to pad the input to the six-digit integer format (I6), but this extra space would be ignored, and the input would be interpreted as ' 2304 '. The blanks following the E or D in real-number input are ignored, regardless of the form of blank interpretation in effect.

Suppose you enter 123 and press Enter in response to the following READ statement:

\[
\text{READ (*, '(I6)')} \ n
\]

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. If BZ editing is in effect, those three blanks are interpreted as zeros, and the record is equal to 123000.

**Scale-Factor Editing (P)**

The P edit descriptor specifies a scale factor, which moves the location of the decimal point in real values and the two real parts of complex values. It takes the following form:

\[ \kappa P \]

The \( \kappa \) is a signed (sign is optional if positive), integer literal constant specifying the number of positions, to the left or right, that the decimal point is to move (the scale factor). The range of \( \kappa \) is \(-128\) to \(127\).

At the beginning of a formatted I/O statement, the value of the scale factor is zero. If a scale editing descriptor is specified, the scale factor is set to the new value, which affects all subsequent real edit descriptors until another scale editing descriptor occurs.

To reinstate a scale factor of zero, you must explicitly specify 0P.

Format reversion does not affect the scale factor. (For more information on format reversion, see [Interaction Between Format Specifications and I/O Lists.](#))
**Rules for Input Processing**

On input, a positive scale factor moves the decimal point to the left, and a negative scale factor moves the decimal point to the right. (On output, the effect is the reverse.)

On input, when an input field using an F, E, D, EN, ES, or G real edit descriptor contains an explicit exponent, the scale factor has no effect. Otherwise, the internal value of the corresponding I/O list item is equal to the external field data multiplied by $10^{-k}$. For example, a 2P scale factor multiplies an input value by .01, moving the decimal point two places to the left. A -2P scale factor multiplies an input value by 100, moving the decimal point two places to the right.

The following shows input using the P edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3PE10.5</td>
<td>^^^37.614^</td>
<td>.037614</td>
</tr>
<tr>
<td>3PE10.5</td>
<td>^^37.614E2</td>
<td>3761.4</td>
</tr>
<tr>
<td>-3PE10.5</td>
<td>^^^^37.614</td>
<td>37614.0</td>
</tr>
</tbody>
</table>

The scale factor must precede the first real edit descriptor associated with it, but it need not immediately precede the descriptor. For example, the following all have the same effect:

- (3P, I6, F6.3, E8.1)
- (I6, 3P, F6.3, E8.1)
- (I6, 3PF6.3, E8.1)

Note that if the scale factor immediately precedes the associated real edit descriptor, the comma separator is optional.

**Rules for Output Processing**

On output, a positive scale factor moves the decimal point to the right, and a negative scale factor moves the decimal point to the left. (On input, the effect is the reverse.)

On output, the effect of the scale factor depends on which kind of real editing is associated with it, as follows:

- For F editing, the external value equals the internal value of the I/O list item multiplied by $10^k$. This changes the magnitude of the data.
- For E and D editing, the external decimal field of the I/O list item is multiplied by $10^k$, and $k$ is subtracted from the exponent. This changes the form of the data.
A positive scale factor decreases the exponent; a negative scale factor increases the exponent. For a positive scale factor, $k$ must be less than $d + 2$ or an output conversion error occurs.

- For G editing, the scale factor has no effect if the magnitude of the data to be output is within the effective range of the descriptor (the G descriptor supplies its own scaling).
  
  If the magnitude of the data field is outside G descriptor range, E editing is used, and the scale factor has the same effect as E output editing.

- For EN and ES editing, the scale factor has no effect.

The following shows output using the P edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1PE12.3</td>
<td>-270.139</td>
<td>^^-2.701E+02</td>
</tr>
<tr>
<td>1PE12.2</td>
<td>-270.139</td>
<td>^^^-2.70E+02</td>
</tr>
<tr>
<td>-1PE12.2</td>
<td>-270.139</td>
<td>^^^-0.03E+04</td>
</tr>
</tbody>
</table>

**Examples**

The following shows a FORMAT statement containing a scale factor:
```
DIMENSION A(6)
DO 10 I=1,6
  10 A(I) = 25.
WRITE (6, 100) A
100 FORMAT(' ', F8.2, 2PF8.2, F8.2)
```

The preceding statements produce the following results:
```
 25.00   2500.00   2500.00
2500.00   2500.00   2500.00
```

The following code uses scale-factor editing when reading:
```
READ (*, 100) a, b, c, d
100 FORMAT (F10.6, 1P, F10.6, F10.6, -2P, F10.6)
WRITE (*, 200) a, b, c, d
200 FORMAT (4F11.3)
```
If the following data is entered:

12340000 12340000 12340000 12340000
12.34 12.34 12.34 12.34
12.34e0 12.34e0 12.34e0 12.34e0
12.34e3 12.34e3 12.34e3 12.34e3

The program's output is:

12.340 1.234 1.234 1234.000
12.340 1.234 1.234 1234.000
12340.000 12340.000 12340.000 12340.000

The next code shows scale-factor editing when writing:

```
a = 12.34
  WRITE (*, 100) a, a, a, a, a, a
100 FORMAT (1X, F9.4, E11.4E2, 1P, F9.4, E11.4E2, &
  & -2P, F9.4, E11.4E2)
```

This program's output is:

12.3400 0.1234E+02 123.4000 1.2340E+01 0.1234 0.0012E+04

See Also
- Control Edit Descriptors
- Forms for Control Edit Descriptors

Slash Editing (/)

The slash edit descriptor terminates data transfer for the current record and starts data transfer for a new record. It takes the following form:

`[r]/`

The `r` is a repeat specification. It must be a positive default integer literal constant; no kind parameter can be specified.

The range of `r` is 1 through 2147483647 (2**31-1) on Intel® 64 architecture and IA-64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. If `r` is omitted, it is assumed to be 1.

Multiple slashes cause the system to skip input records or to output blank records, as follows:
• When \( n \) consecutive slashes appear between two edit descriptors, \( n - 1 \) records are skipped on input, or \( n - 1 \) blank records are output. The first slash terminates the current record. The second slash terminates the first skipped or blank record, and so on.

• When \( n \) consecutive slashes appear at the beginning or end of a format specification, \( n \) records are skipped or \( n \) blank records are output, because the opening and closing parentheses of the format specification are themselves a record initiator and terminator, respectively. For example, suppose the following statements are specified:

```fortran
WRITE (6,99)
99 FORMAT ('1',T51,'HEADING LINE'/T51,'SUBHEADING LINE'/)
```

The following lines are written:

<table>
<thead>
<tr>
<th>Column 50, top of page</th>
<th>HEADING LINE</th>
</tr>
</thead>
<tbody>
<tr>
<td>(blank line)</td>
<td>SUBHEADING LINE</td>
</tr>
<tr>
<td>(blank line)</td>
<td></td>
</tr>
<tr>
<td>(blank line)</td>
<td></td>
</tr>
</tbody>
</table>

Note that the first character of the record printed was reserved as a control character (see Printing of Formatted Records).

### Examples

The following statements write spreadsheet column and row labels:

```fortran
! The following statements write spreadsheet column and row labels:
WRITE (*, 100)
100 FORMAT (' A B C D E' &
& /,' 1',/,' 2',/,' 3',/,' 4',/,' 5')
```

This example generates the following output:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Control Edit Descriptors
- Forms for Control Edit Descriptors
Colon Editing (~)

The colon edit descriptor terminates format control if no more items are in the I/O list.

Examples

Suppose the following statements are specified:

```plaintext
PRINT 1,3
PRINT 2,13
1 FORMAT (' I=',I2,' J=',I2)
2 FORMAT (' K=',I2,:,' L=',I2)
```

The following lines are written (the symbol ^ represents a nonprinting blank character):

```
I=^3^J=
K=13
```

! The following example writes a= 3.20 b= .99

```plaintext
REAL a, b, c, d
DATA a /3.2/, b /.9871515/
WRITE (*, 100) a, b
100 FORMAT (' a=', F5.2, :, ' b=', F5.2, :, &
& ' c=', F5.2, :, ' d=', F5.2)
END
```

Dollar-Sign ($) and Backslash (\) Editing

The dollar sign and backslash edit descriptors modify the output of carriage control specified by the first character of the record. They only affect carriage control for formatted files, and have no effect on input.

If the first character of the record is a blank or a plus sign (+), the dollar sign and backslash descriptors suppress carriage return (after printing the record).
For terminal device I/O, when this trailing carriage return is suppressed, a response follows output on the same line. For example, suppose the following statements are specified:

```
TYPE 100
100 FORMAT (' ENTER RADIUS VALUE ',$)
    ACCEPT 200, RADIUS
200 FORMAT (F6.2)
```

The following prompt is displayed:

```
ENTER RADIUS VALUE
```

Any response (for example, "12.") is then displayed on the same line:

```
ENTER RADIUS VALUE 12.
```

If the first character of the record is 0, 1, or ASCII NUL, the dollar sign and backslash descriptors have no effect.

Consider the following:

```
CHARACTER(20) MYNAME
WRITE (*,9000)
9000 FORMAT ('0Please type your name:',
    READ (*,9001) MYNAME
9001 FORMAT (A20)
    WRITE (*,9002) ' ',MYNAME
9002 FORMAT (1X,A20)
```

This example advances two lines, prompts for input, awaits input on the same line as the prompt, and prints the input.

- Control Edit Descriptors
- Forms for Control Edit Descriptors

Character Count Editing (Q)

The character count edit descriptor returns the remaining number of characters in the current input record.
The corresponding I/O list item must be of type integer or logical. For example, suppose the following statements are specified:

```
READ (4,1000) XRAY, KK, NCHRS, (ICHAR(I), I=1,NCHRS)
```

```
1000 FORMAT (E15.7,I4,Q,(80A1))
```

Two fields are read into variables XRAY and KK. The number of characters remaining in the record is stored in NCHRS, and exactly that many characters are read into the array ICHR. (This instruction can fail if the record is longer than 80 characters.)

If you place the character count descriptor first in a format specification, you can determine the length of an input record.

On output, the character count edit descriptor causes the corresponding I/O list item to be skipped.

**Examples**

Consider the following:

```
CHARACTER ICHAR(80)
```

```
READ (4, 1000) XRAY, K, NCHAR, (ICHAR(I), I= 1, NCHAR)
```

```
1000 FORMAT (E15.7, I4, Q, (80A1))
```

The preceding input statement reads the variables XRAY and K. The number of characters remaining in the record is NCHAR, specified by the Q edit descriptor. The array ICHAR is then filled by reading exactly the number of characters left in the record. (Note that this instruction will fail if NCHAR is greater than 80, the length of the array ICHAR.) By placing Q in the format specification, you can determine the actual length of an input record.

Note that the length returned by Q is the number of characters left in the record, not the number of reals or integers or other data types. The length returned by Q can be used immediately after it is read and can be used later in the same format statement or in a variable format expression. (See Variable Format Expressions.)

Assume the file Q.DAT contains:

```
1234.567Hello, Q Edit
```

2081
The following program reads in the number REAL1, determines the characters left in the record, and reads those into STR:

```
CHARACTER STR(80)
INTEGER LENGTH
REAL REAL1
OPEN (UNIT = 10, FILE = 'Q.DAT')
100 FORMAT (F8.3, Q, 80A1)
READ (10, 100) REAL1, LENGTH, (STR(I), I=1, LENGTH)
WRITE(*,'(F8.3,2X,I2,2X,<LENGTH>A1)') REAL1, LENGTH, (STR(I), &
& I= 1, LENGTH)
END
```

The output on the screen is:

```
1234.567 13 Hello, Q Edit
```

A READ statement that contains only a Q edit descriptor advances the file to the next record. For example, consider that Q.DAT contains the following data:

```
abcdefg
abcd
```

Consider it is then READ with the following statements:

```
OPEN (10, FILE = "Q.DAT")
READ(10, 100) LENGTH
100 FORMAT(Q)
WRITE(*,'(I2)') LENGTH
READ(10, 100) LENGTH
WRITE(*,'(I2)') LENGTH
END
```

The output to the screen would be:

```
7
4
```
Character String Edit Descriptors

Character string edit descriptors control the output of character strings. The character string edit descriptors are the character constant and H edit descriptor.

Although no string edit descriptor can be preceded by a repeat specification, a parenthesized group of string edit descriptors can be preceded by a repeat specification.

See Also
- I/O Formatting
- Character Constant Editing
- H Editing
- Nested and Group Repeat Specifications

Character Constant Editing

The character constant edit descriptor causes a character string to be output to an external record. It takes one of the following forms:

'dstring'
"string"

The string is a character literal constant; no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character.

To include an apostrophe in a character constant that is enclosed by apostrophes, place two consecutive apostrophes ('') in the format specification; for example:

```
50 FORMAT ('TODAY''S^DATE^IS:^',I2,'/',I2,'/',I2)
```

Note that the symbol ^ represents a nonprinting blank character.

Similarly, to include a quotation mark in a character constant that is enclosed by quotation marks, place two consecutive quotation marks (""") in the format specification.

On input, the character constant edit descriptor transfers length of string characters to the edit descriptor.
Examples

Consider the following '(3I5)' format in the WRITE statement:

```fortran
WRITE (10, '(3I5)') I1, I2, I3
```

This is equivalent to:

```fortran
WRITE (10, 100) I1, I2, I3
100 FORMAT( 3I5)
```

The following shows another example:

```fortran
! These WRITE statements both output ABC'DEF
! (The leading blank is a carriage-control character).
WRITE (*, 970)
970 FORMAT (' ABC''DEF')
WRITE (*, '('' ABC''''DEF'')')
```

The following WRITE also outputs ABC'DEF. No carriage-control character is necessary for list-directed I/O.

```fortran
WRITE (*,*) 'ABC'"DEF'
```

Alternatively, if the delimiter is quotation marks, the apostrophe in the character constant ABC'DEF requires no special treatment:

```fortran
WRITE (*,*) "ABC'DEF"
```

H Editing

The H edit descriptor transfers data between the external record and the H edit descriptor itself. The H edit descriptor is a deleted feature in Fortran 95; it was obsolescent in Fortran 90. Intel® Fortran fully supports features deleted in Fortran 95.

An H edit descriptor has the form of a Hollerith constant, as follows:

```
mHstring
```
Is an unsigned, positive default integer literal constant (with no kind parameter) indicating the number of characters in \texttt{string} (including blanks and tabs). The range of $n$ is 1 through $2^{31}-1$ on Intel\textsuperscript{®} 64 architecture and IA-64 architecture; 1 through $2^{15}-1$ on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.

\texttt{string} is a string of printable ASCII characters.

On input, the H edit descriptor transfers $n$ characters from the external field to the edit descriptor. The first character appears immediately after the letter H. Any characters in the edit descriptor before input are replaced by the input characters.

On output, the H edit descriptor causes $n$ characters following the letter H to be output to an external record.

**Examples**

```
! These WRITE statements both print "Don't misspell 'Hollerith'"
! (The leading blanks are carriage-control characters).
! Hollerith formatting does not require you to embed additional
! single quotation marks as shown in the second example.
!
WRITE (*, 960)
960 FORMAT (27H Don't misspell 'Hollerith')
WRITE (*, 961)
961 FORMAT (' Don''t misspell ''Hollerith''')
```

**See Also**

- Character String Edit Descriptors
- Obsolescent and Deleted Language Features
- Format Specifications
Nested and Group Repeat Specifications

Format specifications can include nested format specifications enclosed in parentheses; for example:

\[ 15 \text{ FORMAT (E7.2, I8, I2, (A5, I6))} \]
\[ 35 \text{ FORMAT (A6, (L8(3I2)), A)} \]

A group repeat specification can precede a nested group of edit descriptors. For example, the following statements are equivalent, and the second statement shows a group repeat specification:

\[ 50 \text{ FORMAT (I8, I8, F8.3, E15.7, F8.3, E15.7, F8.3, E15.7, I5, I5)} \]
\[ 50 \text{ FORMAT (2I8, 3(F8.3, E15.7), 2I5)} \]

If a nested group does not show a repeat count, a default count of 1 is assumed.

Normally, the string edit descriptors and control edit descriptors cannot be repeated (except for slash), but any of these descriptors can be enclosed in parentheses and preceded by a group repeat specification. For example, the following statements are valid:

\[ 76 \text{ FORMAT ('MONTHLY', 3('TOTAL'))} \]
\[ 100 \text{ FORMAT (I8, 4(T7), A4)} \]

Variable Format Expressions

A variable format expression is a numeric expression enclosed in angle brackets (< >) that can be used in a FORMAT statement or in character format specifications.

The numeric expression can be any valid Fortran expression, including function calls and references to dummy arguments.

If the expression is not of type integer, it is converted to integer type before being used.

If the value of a variable format expression does not obey the restrictions on magnitude applying to its use in the format, an error occurs.
Variable format expressions cannot be used with the H edit descriptor, and they are not allowed in character format specifications.

Variable format expressions are evaluated each time they are encountered in the scan of the format. If the value of the variable used in the expression changes during the execution of the I/O statement, the new value is used the next time the format item containing the expression is processed.

**Examples**

Consider the following statement:

```plaintext
FORMAT (I<J+1>)
```

When the format is scanned, the preceding statement performs an I (integer) data transfer with a field width of J+1. The expression is reevaluated each time it is encountered in the normal format scan.

Consider the following statements:

```plaintext
DIMENSION A(5)
DATA A/1.,2.,3.,4.,5./
DO 10 I=1,10
  WRITE (6,100) I
100 FORMAT (I<MAX(I,5)>)
10 CONTINUE
DO 20 I=1,5
  WRITE (6,101) (A(I), J=1,I)
20 FORMAT (<I>F10.<I-1>)
20 CONTINUE
END
```
On execution, these statements produce the following output:

1
2
3
4
5
6
7
8
9
10
1.0    2.0
3.00   3.00   3.00
4.000  4.00   4.00   4.00
5.0000 5.0000 5.0000 5.0000 5.0000

The following shows another example:

WRITE(6,20) INT1
20 FORMAT(I<MAX(20,5)>)
WRITE(6,FMT=30) REAL2(10), REAL3
30 FORMAT(<J+K>X, <2*M>F8.3)

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement. For example:

INTEGER width, value
width=2
READ (*,10) width, value
10 FORMAT(II, I <width>)
PRINT *, value
END
When given input 3123, the program will print 123 and not 12.

**See Also**
- I/O Formatting
- Interaction Between Format Specifications and I/O Lists

**Printing of Formatted Records**

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect or the file is being processed by the `fortpr` format utility, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but used to control vertical spacing.

The following table lists the valid control characters for printing:

**Table 622: Control Characters for Printing**

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
<th>Effect</th>

<td>Outputs the record (at the current position in the current line), but no carriage return.</td>
</tr>
</tbody>
</table>

Specify as CHAR( 0 ).
Any other character is interpreted as a blank and is deleted from the print line. If you do not specify a control character for printing, the first character of the record is not printed.

**Interaction Between Format Specifications and I/O Lists**

Format control begins with the execution of a formatted I/O statement. Each action of format control depends on information provided jointly by the next item in the I/O list (if one exists) and the next edit descriptor in the format specification.

Both the I/O list and the format specification are interpreted from left to right, unless repeat specifications or implied-DO lists appear.

If an I/O list specifies at least one list item, at least one data edit descriptor (I, B, O, Z, F, E, EN, ES, D, G, L, or A) or the Q edit descriptor must appear in the format specification; otherwise, an error occurs.

Each data edit descriptor (or Q edit descriptor) corresponds to one item in the I/O list, except that an I/O list item of type complex requires the interpretation of two F, E, EN, ES, D, or G edit descriptors. No I/O list item corresponds to a control edit descriptor (X, P, T, TL, TR, SP, SS, S, BN, BZ, $, or :), or a character string edit descriptor (H and character constants). For character string edit descriptors, data transfer occurs directly between the external record and the format specification.

When format control encounters a data edit descriptor in a format specification, it determines whether there is a corresponding I/O list item specified. If there is such an item, it is transferred under control of the edit descriptor, and then format control proceeds. If there is no corresponding I/O list item, format control terminates.

If there are no other I/O list items to be processed, format control also terminates when the following occurs:

- A colon edit descriptor is encountered.
- The end of the format specification is reached.

If additional I/O list items remain, part or all of the format specification is reused in format reversion.

In format reversion, the current record is terminated and a new one is initiated. Format control then reverts to one of the following (in order) and continues from that point:

1. The group repeat specification whose opening parenthesis matches the next-to-last closing parenthesis of the format specification
2. The initial opening parenthesis of the format specification

Format reversion has no effect on the scale factor (P), the sign control edit descriptors (S, SP, or SS), or the blank interpretation edit descriptors (BN or BZ).
Examples

The data in file FOR002.DAT is to be processed 2 records at a time. Each record starts with a number to be put into an element of a vector B, followed by 5 numbers to be put in a row in matrix A.

FOR002.DAT contains the following data:

001 0101 0102 0103 0104 0105
002 0201 0202 0203 0204 0205
003 0301 0302 0303 0304 0305
004 0401 0402 0403 0404 0405
005 0501 0502 0503 0504 0505
006 0601 0602 0603 0604 0605
007 0701 0702 0703 0704 0705
008 0801 0802 0803 0804 0805
009 0901 0902 0903 0904 0905
010 1001 1002 1003 1004 1005

The following example shows how several different format specifications interact with I/O lists to process data in file FOR002.DAT:

Figure 34: Interaction Between Format Specifications and I/O Lists

```
INTEGER I, J, A(2,5), B(2)

OPEN (unit=2, access='sequential', file='FOR002.DAT')

READ (2,100) (B(I), (A(I,J), J=1,5), I=1,2)

1
100 FORMAT (2(I3, X, 5(I4,X), /) )

2

WRITE (6,999) B, ((A(I,J), J=1,5), I=1,2)
```
999 FORMAT (’ B is ’, 2(I3, X), ’; A is’, /  
      ’ ’, 5 (I4, X))  
      READ (2,200) (B(I), (A(I,J), J=1,5),I=1,2)  

200 FORMAT (2 (I3, X, 5(I4,X), :/) )  
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2)  

READ (2,300) (B(I), (A(I,J), J=1,5),I=1,2)  

300 FORMAT ( (I3, X, 5(I4,X}) )  
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2)  

READ (2,400) (B(I), (A(I,J), J=1,5),I=1,2)  

400 FORMAT ( I3, X, 5(I4,X) )  
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2)
This statement reads B(1); then A(1,1) through A(1,5); then B(2) and A(2,1) through A(2,5).
The first record read (starting with 001) starts the processing of the I/O list.

There are two records, each in the format I3, X, 5(I4, X). The slash (/) forces the reading of the second record after A(1,5) is processed. It also forces the reading of the third record after A(2,5) is processed; no data is taken from that record.

This statement produces the following output:
B is 1 2; A is 101 102 103 104 105 201 202 203 204 205

This statement reads the record starting with 004. The slash (/) forces the reading of the next record after A(1,5) is processed. The colon (:) stops the reading after A(2,5) is processed, but before the slash (/) forces another read.

This statement produces the following output:
B is 4 5; A is 401 402 403 404 405 501 502 503 504 505

This statement reads the record starting with 006. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I3.

This statement produces the following output:
B is 6 7; A is 601 602 603 604 605 701 702 703 704 705

This statement reads the record starting with 008. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I4.

This statement produces the following output:
B is 8 90; A is 801 802 803 804 805 9010 9020 9030 9040 100

The record 009 0901 0902 0903 0904 0905 is processed with I4 as "009 " for B(2), which is 90. X skips the next "0". Then "901 " is processed for A(2,1), which is 9010, "902 " for A(2,2), "903 " for A(2,3), and "904 " for A(2,4). The repeat specification of 5 is now exhausted and the format ends. Format reversion causes another record to be read and starts format processing at the left parenthesis before the I4, so "010 " is read for A(2,5), which is 100.

• Control edit descriptors
• Q edit descriptor
• Character string edit descriptors
• Scale Factor Editing (P)
The following are file connection, inquiry, and positioning I/O statements:

- **BACKSPACE**
  Positions a sequential file at the beginning of the preceding record.

- **CLOSE**
  Terminates the connection between a logical unit and a file or device.

- **DELETE**
  Deletes a record from a relative file.

- **ENDFILE**
  For sequential files, writes an end-of-file record to the file and positions the file after this record. For direct access files, truncates the file after the current record.

- **FLUSH**
  Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.

- **INQUIRE**
  Requests information on the status of specified properties of a file or logical unit.

- **OPEN**
  Connects a Fortran logical unit to a file or device; declares attributes for read and write operations.

- **REWIND**
  Positions a sequential file at the beginning of the file.

- **WAIT**
  Performs a wait operation for a specified pending asynchronous data transfer operation.

</tbody>
</table>
BACKSPACE Statement Overview

The BACKSPACE statement positions a file at the beginning of the preceding record, making it available for subsequent I/O processing.

CLOSE Statement Overview

The CLOSE statement disconnects a file from a unit.

DELETE Statement Overview

The DELETE statement deletes a record from a relative file.

ENDFILE Statement Overview

The ENDFILE statement writes an end-of-file record to a sequential file and positions the file after this record (the terminal point), or it causes a direct access file to be truncated after the current record.

FLUSH Statement Overview

The FLUSH statement makes data written to a file become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement. For more information, see FLUSH.

INQUIRE Statement Overview

The INQUIRE statement returns information on the status of specified properties of a file or logical unit. For more information, see INQUIRE.

The following are inquiry specifiers:

<table>
<thead>
<tr>
<th>ACCESS</th>
<th>DELIM</th>
<th>NAMED</th>
<th>READ</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTION</td>
<td>DIRECT</td>
<td>NEXTREC</td>
<td>READWRITE</td>

<td>EXIST</td>
<td>NUMBER</td>
<td>RECL</td>
</tr>
<tr>
<td>BINARY</td>
<td>FORM</td>
<td>OPENED</td>
<td>RECORDTYPE</td>
</tr>
</tbody>
</table>

53
The **ACCESS** specifier asks how a file is connected. It takes the following form:

\[
\text{ACCESS} = \text{acc}
\]

- \(\text{acc}\) is a scalar default character variable that is assigned one of the following values:
  - **SEQUENTIAL**
  - **STREAM**
  - **DIRECT**
  - **UNDEFINED**

The **ACTION** specifier asks which I/O operations are allowed for a file. It takes the following form:

\[
\text{ACTION} = \text{act}
\]

- \(\text{act}\) is a scalar default character variable that is assigned one of the following values:
  - **READ**
  - **WRITE**
If the file is connected for both input and output

'READWRITE'

If the file is not connected

'UNDEFINED'

---

**INQUIRE: ASYNCHRONOUS Specifier**

The ASYNCHRONOUS specifier asks whether asynchronous I/O is in effect. It takes the following form:

ASYNCHRONOUS = asyn

*asyn* is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NO'</td>
<td>If the file or unit is connected and asynchronous input/output is not in effect.</td>
</tr>
<tr>
<td>'YES'</td>
<td>If the file or unit is connected and asynchronous input/output is in effect.</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file or unit is not connected.</td>
</tr>
</tbody>
</table>

---

**INQUIRE: BINARY Specifier (W*32, W*64)**

The BINARY specifier asks whether a file is connected to a binary file. It takes the following form:

BINARY = bin

*bin* is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file is connected to a binary file</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file is connected to a nonbinary file</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file is not connected.</td>
</tr>
</tbody>
</table>
INQUIRE: BLANK Specifier

The BLANK specifier asks what type of blank control is in effect for a file. It takes the following form:

\[ \text{BLANK} = \text{blnk} \]

\( \text{blnk} \) is a scalar default character variable that is assigned one of the following values:

- 'NULL': If null blank control is in effect for the file.
- 'ZERO': If zero blank control is in effect for the file.
- 'UNDEFINED': If the file is not connected, or it is not connected for formatted data transfer.

INQUIRE: BLOCKSIZE Specifier

The BLOCKSIZE specifier asks about the I/O buffer size. It takes the following form:

\[ \text{BLOCKSIZE} = \text{bks} \]

\( \text{bks} \) is a scalar integer variable.

The \( \text{bks} \) is assigned the current size of the I/O buffer. If the unit or file is not connected, the value assigned is zero.

INQUIRE: BUFFERED Specifier

The BUFFERED specifier asks whether run-time buffering is in effect. It takes the following form:

\[ \text{BUFFERED} = \text{bf} \]

\( \text{bf} \) is a scalar default character variable that is assigned one of the following values:

- 'NO': If the file or unit is connected and buffering is not in effect.
- 'YES': If the file or unit is connected and buffering is in effect.
'UNKNOWN'  If the file or unit is not connected.

INQUIRE: CARRIAGECONTROL Specifier

The CARRIAGECONTROL specifier asks what type of carriage control is in effect for a file. It takes the following form:

```
CARRIAGECONTROL = \( cc \)
```

- \( cc \) is a scalar default character variable that is assigned one of the following values:
  - 'FORTRAN'  If the file is connected with Fortran carriage control in effect
  - 'LIST'  If the file is connected with implied carriage control in effect
  - 'NONE'  If the file is connected with no carriage control in effect
  - 'UNKNOWN'  If the file is not connected

INQUIRE: CONVERT Specifier

The CONVERT specifier asks what type of data conversion is in effect for a file. It takes the following form:

```
CONVERT = \( fm \)
```

- \( fm \) is a scalar default character variable that is assigned one of the following values:
  - 'LITTLE_ENDIAN'  If the file is connected with little endian integer and IEEE* floating-point data conversion in effect
  - 'BIG_ENDIAN'  If the file is connected with big endian integer and IEEE floating-point data conversion in effect
'CRAY'  If the file is connected with big endian integer and CRAY* floating-point data conversion in effect

'FDX'  If the file is connected with little endian integer and VAX* processor F_floating, D_floating, and IEEE X_floating data conversion in effect

'FGX'  If the file is connected with little endian integer and VAX processor F_floating, G_floating, and IEEE X_floating data conversion in effect

'IBM'  If the file is connected with big endian integer and IBM* System\370 floating-point data conversion in effect

'VAXD'  If the file is connected with little endian integer and VAX processor F_floating, D_floating, and H_floating in effect

'VAXG'  If the file is connected with little endian integer and VAX processor F_floating, G_floating, and H_floating in effect

'NATIVE'  If the file is connected with no data conversion in effect

'UNKNOWN'  If the file or unit is not connected for unformatted data transfer

**INQUIRE: DELIM Specifier**

The DELIM specifier asks how character constants are delimited in list-directed and namelist output. It takes the following form:
DELM = \( del \)

\( del \) is a scalar default character variable that is assigned one of the following values:

- **'APOSTROPHE'**: If apostrophes are used to delimit character constants in list-directed and namelist output.
- **'QUOTE'**: If quotation marks are used to delimit character constants in list-directed and namelist output.
- **'NONE'**: If no delimiters are used.
- **'UNDEFINED'**: If the file is not connected, or is not connected for formatted data transfer.

**INQUIRE: DIRECT Specifier**

The DIRECT specifier asks whether a file is connected for direct access. It takes the following form:

\[ \text{DIRECT} = \text{dir} \]

\( dir \) is a scalar default character variable that is assigned one of the following values:

- **'YES'**: If the file is connected for direct access.
- **'NO'**: If the file is not connected for direct access.
- **'UNKNOWN'**: If the file is not connected.

**INQUIRE: EXIST Specifier**

The EXIST specifier asks whether a file exists and can be opened. It takes the following form:

\[ \text{EXIST} = \text{ex} \]

\( ex \) is a scalar default logical variable that is assigned one of the following values:
If the specified file exists and can be opened, or if the specified unit exists.

.TRUE.

If the specified file or unit does not exist or if the file exists but cannot be opened.

.FALSE.

The unit exists if it is a number in the range allowed by the processor.

**INQUIRE: FORM Specifier**

The FORM specifier asks whether a file is connected for formatted, unformatted, or binary (W*32, W*64) data transfer. It takes the following form:

\[ \text{FORM} = \text{fm} \]

\text{fm} \hspace{1cm} \text{Is a scalar default character variable that is assigned one of the following values:}

'|FORMATTED'| If the file is connected for formatted data transfer

'|UNFORMATTED'| If the file is connected for unformatted data transfer

'|BINARY'| If the file is connected for binary data transfer

'|UNDEFINED'| If the file is not connected

**INQUIRE: FORMATTED Specifier**

The FORMATTED specifier asks whether a file is connected for formatted data transfer. It takes the following form:

\[ \text{FORMATTED} = \text{fmt} \]

\text{fmt} \hspace{1cm} \text{Is a scalar default character variable that is assigned one of the following values:}

'|YES'| If the file is connected for formatted data transfer
If the file is not connected for formatted data transfer

'UNOWN'  If the processor cannot determine whether the file is connected for formatted data transfer

INQUIRE: ID Specifier

The ID specifier identifies a pending asynchronous data transfer. It takes the following form:

\[ \text{ID} = iexp \]

\[ iexp \]

Is a scalar integer expression identifying a data transfer operation that was returned using the ID= specifier in a previous asynchronous READ or WRITE statement.

This specifier is used with the PENDING specifier to determine whether a specific asynchronous pending data transfer is completed.

See Also
- INQUIRE Statement Overview
- PENDING specifier

INQUIRE: IOFOCUS Specifier (W*32, W*64)

The IOFOCUS specifier asks if the indicated unit is the active window in a QuickWin application. It takes the following form:

\[ \text{IOFOCUS} = iof \]

\[ iof \]

Is a scalar default logical variable that is assigned one of the following values:

| .TRUE.   | If the specified unit is the active window in a QuickWin application |
| .FALSE.  | If the specified unit is not the active window in a QuickWin application |

If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..
A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window.

If you use this specifier with a non-Windows application, an error occurs.

**INQUIRE: MODE Specifier**

MODE is a nonstandard synonym for ACTION.

**INQUIRE: NAME Specifier**

The NAME specifier returns the name of a file. It takes the following form:

NAME = \textit{nme}

\textit{nme} is a scalar default character variable that is assigned the name of the file to which the unit is connected. If the file does not have a name, \textit{nme} is undefined.

The value assigned to \textit{nme} is not necessarily the same as the value given in the FILE specifier. However, the value that is assigned is always valid for use with the FILE specifier in an OPEN statement, unless the value has been truncated in a way that makes it unacceptable. (Values are truncated if the declaration of \textit{nme} is too small to contain the entire value.)

**NOTE.** The FILE and NAME specifiers are synonyms when used with the OPEN statement, but not when used with the INQUIRE statement.

**See Also**

- **INQUIRE Statement Overview**

  *The appropriate manual in your operating system documentation set* for details on the maximum size of file pathnames

**INQUIRE: NAMED Specifier**

The NAMED specifier asks whether a file is named. It takes the following form:

NAMED = \textit{nmd}

\textit{nmd} is a scalar default logical variable that is assigned one of the following values:

- .TRUE. If the file has a name

---

Intel® Fortran Compiler User and Reference Guides
INQUIRE: NEXTREC Specifier

The NEXTREC specifier asks where the next record can be read or written in a file connected for direct access. It takes the following form:

\[ \text{NEXTREC} = nr \]

\( nr \) is a scalar integer variable that is assigned a value as follows:

- If the file is connected for direct access and a record \( (r) \) was previously read or written, the value assigned is \( r + 1 \).
- If no record has been read or written, the value assigned is 1.
- If the file is not connected for direct access, or if the file position cannot be determined because of an error condition, the value assigned is zero.
- If the file is connected for direct access and a REWIND has been performed on the file, the value assigned is 1.

INQUIRE: NUMBER Specifier

The NUMBER specifier asks the number of the unit connected to a file. It takes the following form:

\[ \text{NUMBER} = num \]

\( num \) is a scalar integer variable. The \( num \) is assigned the number of the unit currently connected to the specified file. If there is no unit connected to the file, the value assigned is -1.

INQUIRE: OPENED Specifier

The OPENED specifier asks whether a file is connected. It takes the following form:

\[ \text{OPENED} = od \]

\( od \) is a scalar default logical variable that is assigned one of the following values:

- \( \text{.TRUE.} \) if the specified file or unit is connected
- \( \text{.FALSE.} \) if the file does not have a name
If the specified file or unit is not connected

INQUIRE: ORGANIZATION Specifier
The ORGANIZATION specifier asks how the file is organized. It takes the following form:
ORGANIZATION = \textit{org}
\textit{org} is a scalar default character variable that is assigned one of the following values:
- 'SEQUENTIAL' if the file is a sequential file
- 'RELATIVE' if the file is a relative file
- 'UNKNOWN' if the processor cannot determine the file's organization

INQUIRE: PAD Specifier
The PAD specifier asks whether blank padding was specified for the file. It takes the following form:
PAD = \textit{pd}
\textit{pd} is a scalar default character variable that is assigned one of the following values:
- 'NO' if the file or unit was connected with PAD='NO'
- 'YES' if the file or unit is not connected, or it was connected with PAD='YES'

INQUIRE: PENDING Specifier
The PENDING specifier asks whether previously pending asynchronous data transfers are complete. A data transfer is previously pending if it is not complete at the beginning of execution of the INQUIRE statement. It takes the following form:
PENDING = \textit{pnd}
Is a scalar default logical variable that is assigned the value .TRUE. or .FALSE.. The value is assigned as follows:

- If an ID specifier appears in the INQUIRE statement, the following occurs:
  - If the data transfer specified by ID is complete, then variable \( pnd \) is set to .FALSE. and INQUIRE performs the WAIT operation for the specified data transfer.
  - If the data transfer specified by ID is not complete, then variable \( pnd \) is set to .TRUE. and no WAIT operation is performed. The previously pending data transfer remains pending after the execution of the INQUIRE statement.

- If an ID specifier does not appear in the INQUIRE statement, the following occurs:
  - If all previously pending data transfers for the specified unit are complete, then variable \( pnd \) is set to .FALSE. and the INQUIRE statement performs WAIT operations for all previously pending data transfers for the specified unit.
  - If there are data transfers for the specified unit that are not complete, then variable \( pnd \) is set to .TRUE. and no WAIT operations are performed. The previously pending data transfers remain pending after the execution of the INQUIRE statement.

**See Also**

**INQUIRE: POS Specifier**

The POS specifier identifies the file position in file storage units in a stream file. It takes the following form:

\[
\text{POS} = p
\]

Is a scalar integer variable that is assigned the number of the file storage unit immediately following the current position of a file connected for stream access (ACCESS='STREAM').

If the file is positioned at its terminal position, \( p \) is assigned a value one greater than the number of the highest-numbered file storage unit in the file.

If the file is not connected for stream access or if the position of the file is indeterminate because of previous error conditions, \( p \) is assigned the value one.
INQUIRE: POSITION Specifier

The POSITION specifier asks the position of the file. It takes the following form:

\[
\text{POSITION} = pos
\]

Is a scalar default character variable that is assigned one of the following values:

- 'REWIND': If the file is connected with its position at its initial point
- 'APPEND': If the file is connected with its position at its terminal point (or before its end-of-file record, if any)
- 'ASIS': If the file is connected without changing its position
- 'UNDEFINED': If the file is not connected, or is connected for direct access data transfer and a REWIND statement has not been performed on the unit

See Also

- INQUIRE Statement Overview

Building Applications for details on record position, advancement, and transfer

INQUIRE: READ Specifier

The READ specifier asks whether a file can be read. It takes the following form:

\[
\text{READ} = rd
\]

Is a scalar default character variable that is assigned one of the following values:

- 'YES': If the file can be read
- 'NO': If the file cannot be read
'UNKNOWN'  If the processor cannot determine whether the file can be read

**INQUIRE: READWRITE Specifier**

The READWRITE specifier asks whether a file can be both read and written to. It takes the following form:

\[ \text{READWRITE} = \text{rdwr} \]

\textit{rdwr}  Is a scalar default character variable that is assigned one of the following values:

- 'YES'  If the file can be both read and written to
- 'NO'  If the file cannot be both read and written to
- 'UNKNOWN'  If the processor cannot determine whether the file can be both read and written to

**INQUIRE: RECL Specifier**

The RECL specifier asks the maximum record length for a file. It takes the following form:

\[ \text{RECL} = \text{rcl} \]

\textit{rcl}  Is a scalar integer variable that is assigned a value as follows:

- If the file or unit is connected, the value assigned is the maximum record length allowed.
- If the file does not exist, or is not connected, the value assigned is zero.

The assigned value is expressed in 4-byte units if the file is currently (or was previously) connected for unformatted data transfer; otherwise, the value is expressed in bytes.

**INQUIRE: RECORDTYPE Specifier**

The RECORDTYPE specifier asks which type of records are in a file. It takes the following form:
**RECORDTYPE = rtype**

*rtype* is a scalar default character variable that is assigned one of the following values:

- `'FIXED'` If the file is connected for fixed-length records
- `'VARIABLE'` If the file is connected for variable-length records
- `'SEGMENTED'` If the file is connected for unformatted sequential data transfer using segmented records
- `'STREAM'` If the file's records are not terminated
- `'STREAM_CR'` If the file's records are terminated with a carriage return
- `'STREAM_LF'` If the file's records are terminated with a line feed
- `'STREAM_CRLF'` If the file's records are terminated with a carriage return/line feed pair
- `'UNKNOWN'` If the file is not connected

**INQUIRE: SEQUENTIAL Specifier**

The SEQUENTIAL specifier asks whether a file is connected for sequential access. It takes the following form:

**SEQUENTIAL = seq**

*seq* is a scalar default character variable that is assigned one of the following values:

- `'YES'` If the file is connected for sequential access
- `'NO'` If the file is not connected for sequential access
If the processor cannot determine whether the file is connected for sequential access

**INQUIRE: SHARE Specifier**

The SHARE specifier asks the current share status of a file or unit. It takes the following form:

\[
\text{SHARE} = shr
\]

- **shr** is a scalar default character variable.

On Windows* systems, this variable is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DENYRW'</td>
<td>If the file is connected for deny-read/write mode</td>
</tr>
<tr>
<td>'DENYWR'</td>
<td>If the file is connected for deny-write mode</td>
</tr>
<tr>
<td>'DENYRD'</td>
<td>If the file is connected for deny-read mode</td>
</tr>
<tr>
<td>'DENYNONE'</td>
<td>If the file is connected for deny-none mode</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file or unit is not connected</td>
</tr>
</tbody>
</table>

On Linux* and Mac OS* X systems, this variable is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DENYRW'</td>
<td>If the file is connected for exclusive access</td>
</tr>
<tr>
<td>'DENYNONE'</td>
<td>If the file is connected for shared access</td>
</tr>
<tr>
<td>'NODENY'</td>
<td>If the file is connected with default locking</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file or unit is not connected</td>
</tr>
</tbody>
</table>
**INQUIRE: UNFORMATTED Specifier**

The UNFORMATTED specifier asks whether a file is connected for unformatted data transfer. It takes the following form:

\[ \text{UNFORMATTED} = \text{unf} \]

\[ \text{unf} \]

Is a scalar default character variable that is assigned one of the following values:

- 'YES' If the file is connected for unformatted data transfer
- 'NO' If the file is not connected for unformatted data transfer
- 'UNKNOWN' If the processor cannot determine whether the file is connected for unformatted data transfer

**INQUIRE: WRITE Specifier**

The WRITE specifier asks whether a file can be written to. It takes the following form:

\[ \text{WRITE} = \text{wr} \]

\[ \text{wr} \]

Is a scalar default character variable that is assigned one of the following values:

- 'YES' If the file can be written to
- 'NO' If the file cannot be written to
- 'UNKNOWN' If the processor cannot determine whether the file can be written to

**OPEN Statement Overview**

The OPEN statement connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection. For more information, see OPEN.
The following table summarizes the OPEN statement specifiers and their values (and contains links to their descriptions):

**Table 652: OPEN Statement Specifiers and Values**

</tbody>
</table>

1 If you use the compiler option specifying OpenVMS defaults, and the unit is connected to a terminal, the default is 'FORTRAN'.

2 n is the unit number.

3 If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..

4 For information on file sharing, see Building Applications.

5 On Linux* and Mac OS* X systems, the default depends only on the FORM setting.

6 W*32, W*64

7 The default differs under certain conditions (see SHARE Specifier).

8 The default differs under certain conditions (see STATUS Specifier).

**Key to Values**

- c_expr: A scalar default character expression
- func: An external function
- label: A statement label
- n_expr: A scalar numeric expression
- var: A scalar integer variable
**OPEN: ACCESS Specifier**

The ACCESS specifier indicates the access method for the connection of the file. It takes the following form:

\[ \text{ACCESS} = \text{acc} \]

*acc* is a scalar default character expression that evaluates to one of the following values:

- 'DIRECT': Indicates direct access.
- 'SEQUENTIAL': Indicates sequential access.
- 'STREAM': Indicates stream access, where the file storage units of the file are accessible sequentially or by position.
- 'APPEND': Indicates sequential access, but the file is positioned at the end-of-file record.

The default is 'SEQUENTIAL'.

There are limitations on record access by file organization and record type. For more information, see *Building Applications*.

**OPEN: ACTION Specifier**

The ACTION specifier indicates the allowed I/O operations for the file connection. It takes the following form:

\[ \text{ACTION} = \text{act} \]

*act* is a scalar default character expression that evaluates to one of the following values:

- 'READ': Indicates that only READ statements can refer to this connection.
- 'WRITE': Indicates that only WRITE, DELETE, and ENDFILE statements can refer to this connection.
'READWRITE' Indicates that READ, WRITE, DELETE, and ENDFILE statements can refer to this connection.

The default is 'READWRITE'.

However, if compiler option fpscomp general is specified on the command line and action is omitted, the system first attempts to open the file with 'READWRITE'. If this fails, the system tries to open the file again, first using 'READ', then using 'WRITE'.

Note that in this case, omitting action is not the same as specifying ACTION='READWRITE'. If you specify ACTION='READWRITE' and the file cannot be opened for both read and write access, the attempt to open the file fails. You can use the INQUIRE statement to determine the actual access mode selected.

See Also
- OPEN Statement Overview
- fpscomp compiler option

OPEN: ASSOCIATEVARIABLE Specifier

The ASSOCIATEVARIABLE specifier indicates a variable that is updated after each direct access I/O operation, to reflect the record number of the next sequential record in the file. It takes the following form:

ASSOCIATEVARIABLE = asv

asv Is a scalar integer variable. It cannot be a dummy argument to the routine in which the OPEN statement appears.

Direct access READs, direct access WRITEs, and the FIND, DELETE, and REWRITE statements can affect the value of asv.

This specifier is valid only for direct access; it is ignored for other access modes.

OPEN: ASYNCHRONOUS Specifier

The ASYNCHRONOUS specifier indicates whether asynchronous I/O is allowed for a unit. It takes the following form:

ASYNCHRONOUS = asyn

asyn Is a scalar expression of type default character that evaluates to one of the following values:
Indicates that asynchronous I/O is allowed for a unit.

'YES'

Indicates that asynchronous I/O is not allowed for a unit.

'NO'

The default is 'NO'.

**OPEN: BLANK Specifier**

The BLANK specifier indicates how blanks are interpreted in a file. It takes the following form:

```plaintext
BLANK = blnk
```

*blnk* is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NULL'</td>
<td>Indicates all blanks are ignored, except for an all-blank field (which has a value of zero).</td>
</tr>
<tr>
<td>'ZERO'</td>
<td>Indicates all blanks (other than leading blanks) are treated as zeros.</td>
</tr>
</tbody>
</table>

The default is 'NULL' (for explicitly OPENed files, preconnected files, and internal files). If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'ZERO'.

If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks.

**See Also**

- OPEN Statement Overview
- Blank Editing
- f66

**OPEN: BLOCKSIZE Specifier**

The BLOCKSIZE specifier indicates the physical I/O transfer size for the file. It takes the following form:

```plaintext
BLOCKSIZE = bks
```
\( bks \) is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

If you specify a nonzero number for \( bks \), it is rounded up to a multiple of 512 byte blocks.

If you do not specify BLOCKSIZE or you specify zero for \( bks \), the filesystem default value is assumed.

Note that blocksize is meaningful for sequential access only.

**OPEN: BUFFERCOUNT Specifier**

The BUFFERCOUNT specifier indicates the number of buffers to be associated with the unit for multibuffered I/O. It takes the following form:

\[
\text{BUFFERCOUNT} = bc
\]

\( bc \) is a scalar numeric expression in the range 1 through 127. If necessary, the value is converted to integer data type before use.

The BLOCKSIZE specifier determines the size of each buffer. For example, if BUFFERCOUNT=3 and BLOCKSIZE=2048, the total number of bytes allocated for buffers is 3*2048, or 6144 bytes.

If you do not specify BUFFERCOUNT or you specify zero for \( bc \), the default is 1.

**See Also**

- OPEN Statement Overview
- BLOCKSIZE specifier

*Optimizing Applications* for details on obtaining optimal run-time performance

**OPEN: BUFFERED Specifier**

The BUFFERED specifier indicates run-time library behavior following WRITE operations. It takes the following form:

\[
\text{BUFFERED} = bf
\]

\( bf \) is a scalar default character expression that evaluates to one of the following values:

- ‘NO’ Requests that the run-time library send output data to the file system after each WRITE operation.
'YES' Requests that the run-time library accumulate output data in its internal buffer, possibly across several WRITE operations, before the data is sent to the file system. Buffering may improve run-time performance for output-intensive applications.

The default is 'NO'.

If BUFFERED='YES' is specified, the request may or may not be honored, depending on the output device and other file or connection characteristics.

For direct access, you should specify BUFFERED='YES', although using direct-access I/O to a network file system may be much slower.

If BLOCKSIZE and BUFFERCOUNT have been specified for OPEN, their product determines the size in bytes of the internal buffer. Otherwise, the default size of the internal buffer is 8192 bytes.

**NOTE.** On Windows systems, the default size of the internal buffer is 1024 bytes if compiler option fpscomp general is used.

The internal buffer will grow to hold the largest single record but will never shrink.

**OPEN: CARRIAGECONTROL Specifier**

The CARRIAGECONTROL specifier indicates the type of carriage control used when a file is displayed at a terminal. It takes the following form:

CARRIAGECONTROL = \texttt{cc}

\texttt{cc} is a scalar default character expression that evaluates to one of the following values:

- 'FORTRAN' Indicates normal Fortran interpretation of the first character.
- 'LIST' Indicates one line feed between records.
Indicates no carriage control processing.

The default for binary (W*32, W*64) and unformatted files is 'NONE'. The default for formatted files is 'LIST'. However, if you specify compiler option vms or fpscomp general, and the unit is connected to a terminal, the default is 'FORTRAN'.

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect or the file was processed by the fortpr format utility, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but is used to control vertical spacing.

See Also
• OPEN Statement Overview
• Printing of Formatted Records
• vms
• fpscomp

OPEN: CONVERT Specifier

The CONVERT specifier indicates a nonnative numeric format for unformatted data. It takes the following form:

CONVERT = fm

fm is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'LITTLE_ENDIAN'</td>
<td>Little endian integer data and IEEE* floating-point data.</td>
</tr>
<tr>
<td>'BIG_ENDIAN'</td>
<td>Big endian integer data and IEEE floating-point data.</td>
</tr>
<tr>
<td>'CRAY'</td>
<td>Big endian integer data and CRAY* floating-point data of size REAL(8) or COMPLEX(8).</td>
</tr>
<tr>
<td>'FDX'</td>
<td>Little endian integer data and VAX* processor floating-point data of format F_floating for REAL(4) or COMPLEX(4),</td>
</tr>
</tbody>
</table>
D-floating for size REAL(8) or COMPLEX(8), and IEEE X-floating for REAL(16) or COMPLEX(16).

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'FGX'</code></td>
<td>Little endian integer data ² and VAX processor floating-point data of format F-floating for REAL(4) or COMPLEX(4), G-floating for size REAL(8) or COMPLEX(8), and IEEE X-floating for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td><code>'IBM'</code></td>
<td>Big endian integer data ² and IBM* System\370 floating-point data of size REAL(4) or COMPLEX(4) (IBM short 4), and size REAL(8) or COMPLEX(8) (IBM long 8).</td>
</tr>
<tr>
<td><code>'VAXD'</code></td>
<td>Little endian integer data ² and VAX processor floating-point data of format F-floating for size REAL(4) or COMPLEX(4), D-floating for size REAL(8) or COMPLEX(8), and H-floating for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td><code>'VAXG'</code></td>
<td>Little endian integer data ² and VAX processor floating-point data of format F-floating for size REAL(4) or COMPLEX(4), G-floating for size REAL(8) or COMPLEX(8), and H-floating for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td><code>'NATIVE'</code></td>
<td>No data conversion. This is the default.</td>
</tr>
</tbody>
</table>

¹ INTEGER(1) data is the same for little endian and big endian.

² Of the appropriate size: INTEGER(1), INTEGER(2), INTEGER(4), or INTEGER(8)

³ Of the appropriate size and type: REAL(4), REAL(8), REAL(16), COMPLEX(4), COMPLEX(8), or COMPLEX(16)
You can use CONVERT to specify multiple formats in a single program, usually one format for each specified unit number.

When reading a non-native format, the non-native format on disk is converted to native format in memory. If a converted non-native value is outside the range of the native data type, a run-time message appears.

There are other ways to specify numeric format for unformatted files: you can specify an environment variable, compiler option convert, or OPTIONS/CONVERT. The following shows the order of precedence:

<table>
<thead>
<tr>
<th>Method Used</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>An environment variable</td>
<td>Highest</td>
</tr>
<tr>
<td>OPEN (CONVERT=)</td>
<td></td>
</tr>
<tr>
<td>OPTIONS/CONVERT</td>
<td></td>
</tr>
<tr>
<td>The convert compiler option</td>
<td>Lowest</td>
</tr>
</tbody>
</table>

Compiler option convert and OPTIONS/CONVERT affect all unit numbers used by the program, while environment variables and OPEN (CONVERT=) affect specific unit numbers.

The following example shows how to code the OPEN statement to read unformatted CRAY* numeric data from unit 15, which might be processed and possibly written in native little endian format to unit 20:

```fortran
OPEN (CONVERT='CRAY', FILE='graph3.dat', FORM='UNFORMATTED',
1 UNIT=15)
...
OPEN (FILE='graph3native.dat', FORM='UNFORMATTED', UNIT=20)
```

- OPEN Statement Overview
- Data Types, Constants, and Variables
- convert compiler option

Building Applications: Setting Environment Variables
Building Applications: Run-Time Environment Variables
Building Applications for details on supported ranges for data types
OPEN: DEFAULTFILE Specifier

The DEFAULTFILE specifier indicates a default file pathname string. It takes the following form:

```
DEFAULTFILE = def
```

*def*  
Is a character expression indicating a default file pathname string. The default file pathname string is used primarily when accepting file pathnames interactively. File pathnames known to a user program normally appear in the FILE specifier.

DEFAULTFILE supplies a value to the Fortran I/O system that is prefixed to the name that appears in FILE.

If *def* does not end in a slash (/), a slash is added.

If DEFAULTFILE is omitted, the Fortran I/O system uses the current working directory.

OPEN: DELIM Specifier

The DELIM specifier indicates what characters (if any) are used to delimit character constants in list-directed and namelist output. It takes the following form:

```
DELIM = del
```

*del*  
Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'APOSTROPHE'</td>
<td>Indicates apostrophes delimit character constants. All internal apostrophes are doubled.</td>
</tr>
<tr>
<td>'QUOTE'</td>
<td>Indicates quotation marks delimit character constants. All internal quotation marks are doubled.</td>
</tr>
<tr>
<td>'NONE'</td>
<td>Indicates character constants have no delimiters. No internal apostrophes or quotation marks are doubled.</td>
</tr>
</tbody>
</table>

The default is 'NONE'.

The DELIM specifier is only allowed for files connected for formatted data transfer; it is ignored during input.
OPEN: DISPOSE Specifier

The DISPOSE (or DISP) specifier indicates the status of the file after the unit is closed. It takes one of the following forms:

**DISPOSE = dis**

**DISP = dis**

*dis* is a scalar default character expression that evaluates to one of the following values:

- **'KEEP' or 'SAVE'** Retains the file after the unit closes.
- **'DELETE'** Deletes the file after the unit closes.
- **'PRINT'** Submits the file to the line printer spooler and retains it.
- **'PRINT/DELETE'** Submits the file to the line printer spooler and then deletes it.
- **'SUBMIT'** Forks a process to execute the file.
- **'SUBMIT/DELETE'** Forks a process to execute the file, and then deletes the file after the fork is completed.

1 Use only on sequential files.

The default is 'DELETE' for scratch files. For all other files, the default is 'KEEP'.

OPEN: FILE Specifier

The FILE specifier indicates the name of the file to be connected to the unit. It takes the following form:

**FILE = name**
The name can be any pathname allowed by the operating system. Any trailing blanks in the name are ignored.

If the following conditions occur:

- FILE is omitted
- The unit is not connected to a file
- STATUS='SCRATCH' is not specified
- The corresponding FORTn environment variable is not set for the unit number

then Intel® Fortran generates a file name in the form fort.n, where n is the logical unit number. On Windows systems, if compiler option fpscomp general is specified, omitting FILE implies STATUS='SCRATCH'.

If the file name is stored in a numeric scalar or array, the name must consist of ASCII characters terminated by an ASCII null character (zero byte). However, if it is stored in a character scalar or array, it must not contain a zero byte.

On Windows systems, if the filename is 'USER' or 'CON', input and output are directed to the console. For a complete list of device names, see Physical Devices in Building Applications.

In a Windows* QuickWin application, you can specify FILE='USER' to open a child window. All subsequent I/O statements directed to that unit appear in the child window.

On Windows systems, the name can be blank (FILE=' ') if the compatibility compiler option fpscomp filesfromcmd is specified. If the name is blank, the following occurs:

1. The program reads a filename from the list of arguments (if any) in the command line that started the program. If the argument is a null or blank string (""), you are prompted for the corresponding filename. Each successive OPEN statement that specifies a blank name reads the next following command-line argument.

2. If no command-line arguments are specified or there are no more arguments in the list, you are prompted for additional filenames.

Assume the following command line started the program MYPROG (note that quotation marks (") are used):

    myprog first.fil " " third.txt

MYPROG contains four OPEN statements with blank filenames, in the following order:

    OPEN (2, FILE = ' ')
    OPEN (4, FILE = ' ')
    OPEN (5, FILE = ' ')
    OPEN (10, FILE = ' ')
Unit 2 is associated with the file FIRST.FIL. Because a blank argument was specified on the command line for the second filename, the OPEN statement for unit 4 produces the following prompt:

Filename missing or blank - Please enter name UNIT 4?

Unit 5 is associated with the file THIRD.TXT. Because no fourth file was specified on the command line, the OPEN statement for unit 10 produces the following prompt:

Filename missing or blank - Please enter name UNIT 10?

**See Also**
- OPEN Statement Overview
- fpscomp compiler option

*Building Applications: Physical Devices*

*Building Applications* for details on default file name conventions

The appropriate manual in your system documentation set for details on allowable file pathnames

**OPEN: FORM Specifier**

The FORM specifier indicates whether the file is being connected for formatted, unformatted, or *binary (W*32, W*64) data transfer*. It takes the following form:

\[
\text{FORM} = f_m
\]

\(f_m\) is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FORMATTED'</td>
<td>Indicates formatted data transfer</td>
</tr>
<tr>
<td>'UNFORMATTED'</td>
<td>Indicates unformatted data transfer</td>
</tr>
<tr>
<td>'BINARY'</td>
<td>Indicates binary data transfer</td>
</tr>
</tbody>
</table>

The default is 'FORMATTED' for sequential access files, and 'UNFORMATTED' for direct access files.

The data is stored and retrieved in a file according to the file's access (set by the ACCESS specifier) and the form of the data the file contains.

A *formatted file* is a sequence of formatted records. Formatted records are a series of ASCII characters terminated by an end-of-record mark (a carriage return and line feed sequence). The records in a formatted direct-access file must all be the same length. The records in a formatted sequential file can have varying lengths. All internal files must be formatted.
An unformatted file is a sequence of unformatted records. An unformatted record is a sequence of values. Unformatted direct files contain only this data, and each record is padded to a fixed length with undefined bytes. Unformatted sequential files contain the data plus information that indicates the boundaries of each record.

Binary sequential files are sequences of bytes with no internal structure. There are no records. The file contains only the information specified as I/O list items in WRITE statements referring to the file.

Binary direct files have very little structure. A record length is assigned by the RECL specifier in an OPEN statement. This establishes record boundaries, which are used only for repositioning and padding before and after read and write operations and during BACKSPACE operations. Record boundaries do not restrict the number of bytes that can be transferred during a read or write operation. If an I/O operation attempts to read or write more values than are contained in a record, the read or write operation is continued on the next record.

OPEN: IOFOCUS Specifier (W*32, W*64)

The IOFOCUS specifier indicates whether a particular unit is the active window in a QuickWin application. It takes the following form:

IOFOCUS = \textit{iof}

\textit{iof} is a scalar default logical expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>\textbf{iof}</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.TRUE.</td>
<td>Indicates the QuickWin child window is the active window</td>
</tr>
<tr>
<td>.FALSE.</td>
<td>Indicates the QuickWin child window is not the active window</td>
</tr>
</tbody>
</table>

If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..

A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window. OUTTEXT, OUTGTEXT, or any other graphics routine call does not cause the focus to shift.

See Also
- OPEN Statement Overview
- Building Applications: Giving a Window Focus and Setting the Active Window
OPEN: MAXREC Specifier

The MAXREC specifier indicates the maximum number of records that can be transferred from or to a direct access file while the file is connected. It takes the following form:

\[ \text{MAXREC} = \text{mr} \]

\(mr\) is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

The default is an unlimited number of records.

OPEN: MODE Specifier

MODE is a nonstandard synonym for ACTION.

OPEN: NAME Specifier

NAME is a nonstandard synonym for FILE.

OPEN: NOSHARED Specifier

The NOSHARED specifier indicates that the file is connected for exclusive access by the program. It takes the following form:

\[ \text{NOSHARED} \]

See Also
- OPEN Statement Overview

Building Applications for details on file sharing

OPEN: ORGANIZATION Specifier

The ORGANIZATION specifier indicates the internal organization of the file. It takes the following form:

\[ \text{ORGANIZATION} = \text{org} \]

\(org\) is a scalar default character expression that evaluates to one of the following values:

- 'SEQUENTIAL' indicates a sequential file.
- 'RELATIVE' indicates a relative file.
The default is 'SEQUENTIAL'.

**OPEN: PAD Specifier**

The PAD specifier indicates whether a formatted input record is padded with blanks when an input list and format specification requires more data than the record contains.

The PAD specifier takes the following form:

\[ \text{PAD} = pd \]

- **pd** is a scalar default character expression that evaluates to one of the following values:
  - 'YES': Indicates the record will be padded with blanks when necessary.
  - 'NO': Indicates the record will not be padded with blanks. The input record must contain the data required by the input list and format specification.

The default is 'YES'.

This behavior is different from FORTRAN 77, which never pads short records with blanks. For example, consider the following:

```fortran
READ (5, '(I5)') J
```

If you enter 123 followed by a carriage return, FORTRAN 77 turns the I5 into an I3 and J is assigned 123.

However, Intel Fortran pads the 123 with 2 blanks unless you explicitly open the unit with PAD='NO'.

You can override blank padding by explicitly specifying the BN edit descriptor.

The PAD specifier is ignored during output.

**OPEN: POSITION Specifier**

The POSITION specifier indicates the position of a file connected for sequential access. It takes the following form:

\[ \text{POSITION} = pos \]

- **pos** is a scalar default character expression that evaluates to one of the following values:
\begin{tabular}{|l|l|}
\hline
\textbf{'ASIS'} & Indicates the file position is unchanged if the file exists and is already connected. The position is unspecified if the file exists but is not connected. \\
\hline
\textbf{'REWIND'} & Indicates the file is positioned at its initial point. \\
\hline
\textbf{'APPEND'} & Indicates the file is positioned at its terminal point (or before its end-of-file record, if any). \\
\hline
\end{tabular}

The default is 'ASIS'. (On Fortran I/O systems, this is the same as 'REWIND'.)

A new file (whether specified as new explicitly or by default) is always positioned at its initial point.

In addition to the POSITION specifier, you can use position statements. The BACKSPACE statement positions a file back one record. The REWIND statement positions a file at its initial point. The ENDFILE statement writes an end-of-file record at the current position and positions the file after it. Note that ENDFILE does not go the end of an existing file, but creates an end-of-file where it is.

\section*{See Also}
- OPEN Statement Overview
- \textit{Building Applications} for details on record position, advancement, and transfer

\section*{OPEN: READONLY Specifier}

The READONLY specifier indicates only READ statements can refer to this connection. It takes the following form:

\begin{verbatim}
READONLY
\end{verbatim}

READONLY is similar to specifying ACTION='READ', but READONLY prevents deletion of the file if it is closed with STATUS='DELETE' in effect.

The Fortran I/O system's default privileges for file access are READWRITE. If access is denied, the I/O system automatically retries accessing the file for READ access.

However, if you use compiler option vms, the I/O system does not retry accessing for READ access. So, run-time I/O errors can occur if the file protection does not permit WRITE access. To prevent such errors, if you wish to read a file for which you do not have write access, specify READONLY.
**OPEN: RECL Specifier**

The RECL specifier indicates the length of each record in a file connected for direct access, or the maximum length of a record in a file connected for sequential access.

The RECL specifier takes the following form:

\[
\text{RECL} = rl
\]

\( rl \) is a positive numeric expression indicating the length of records in the file. If necessary, the value is converted to integer data type before use.

If the file is connected for formatted data transfer, the value must be expressed in bytes (characters). Otherwise, the value is expressed in 4-byte units (longwords). If the file is connected for unformatted data transfer, the value can be expressed in bytes if compiler option assume byterecl is specified.

**Except for segmented records**, the \( rl \) is the length for record data only, it does not include space for control information. If \( rl \) is too large, you can exhaust your program’s virtual memory resources trying to create room for the record.

The length specified is interpreted depending on the type of records in the connected file, as follows:

- **For segmented records**, RECL indicates the maximum length for any segment (including the four bytes of control information).
- **For fixed-length records**, RECL indicates the size of each record; it **must** be specified. If the records are unformatted, the size must be expressed as an even multiple of four.

  You can use the **RECL** specifier in an INQUIRE statement to get the record length before opening the file.

- **For variable-length records**, RECL indicates the maximum length for any record.

If you read a fixed-length file with a record length different from the one used to create the file, indeterminate results can occur.

The maximum length for \( rl \) depends on the record type and the setting of the **CARRIAGECONTROL** specifier, as shown in the following table:

<table>
<thead>
<tr>
<th>Record Type</th>
<th>CARRIAGECONTROL</th>
<th>Formatted (size in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed-length</td>
<td>'NONE'</td>
<td>2147483647 (2**31-1)</td>
</tr>
<tr>
<td>Variable-length</td>
<td>'NONE'</td>
<td>2147483640 (2**31-8)</td>
</tr>
</tbody>
</table>
Subtract 1 if compiler option vms is used.

The default value depends on the setting of the RECORDTYPE specifier, as shown in the following table:

### Table 669: Default Record Lengths (RECL)

<table>
<thead>
<tr>
<th>RECORDTYPE</th>
<th>RECL value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td>None; value must be explicitly specified.</td>
</tr>
<tr>
<td>All other settings</td>
<td>132 bytes for formatted records; 510 longwords for unformatted records.¹</td>
</tr>
</tbody>
</table>

¹To change the default record length values, you can use environment variable FORT_FMT_RECL or FORT_UFMT_RECL.

For formatted records with other than RECORDTYPE='FIXED', the default RECL is 132. For example, you can write record lengths of 132 characters without a "maximum record length exceeded" error. However, after 80 characters, the remaining characters will wrap to the next line. Therefore, writing 100 characters will produce two lines of output. This is a property of terminal format files called the right margin. If you do not specify a RECL, this right margin is set to 80; otherwise, it is set to the value of the RECL.

**See Also**
- OPEN Statement Overview
- assume byterecl compiler option
- vms compiler option
OPEN: RECORDSIZE Specifier
RECORDSIZE is a nonstandard synonym for RECL.

OPEN: RECORDTYPE Specifier
The RECORDTYPE specifier indicates the type of records in a file. It takes the following form:

\[ \text{RECORDTYPE} = \text{typ} \]

\text{typ} \quad \text{Is a scalar default character expression that evaluates to one of the following values:}

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td>Indicates fixed-length records.</td>
</tr>
<tr>
<td>'VARIABLE'</td>
<td>Indicates variable-length records.</td>
</tr>
<tr>
<td>'SEGMENTED'</td>
<td>Indicates segmented records.</td>
</tr>
<tr>
<td>'STREAM'</td>
<td>Indicates stream-type variable length data with no record terminators.</td>
</tr>
<tr>
<td>'STREAM_LF'</td>
<td>Indicates stream-type variable length records, terminated with a line feed.</td>
</tr>
<tr>
<td>'STREAM_CR'</td>
<td>Indicates stream-type variable length records, terminated with a carriage return.</td>
</tr>
<tr>
<td>'STREAM_CRLF'</td>
<td>Indicates stream-type variable length records, terminated with a carriage return/line feed pair.</td>
</tr>
</tbody>
</table>

When you open a file, default record types are as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td>For relative files</td>
</tr>
<tr>
<td>'FIXED'</td>
<td>For direct access sequential files</td>
</tr>
<tr>
<td>'STREAM_LF'</td>
<td>For formatted sequential access files on Linux* and Mac OS* X systems</td>
</tr>
</tbody>
</table>
'STREAM_CRLF' For formatted sequential access files on Windows systems

'VARIABLE' For unformatted sequential access files

A segmented record is a logical record consisting of segments that are physical records. Since the length of a segmented record can be greater than 65,535 bytes, only use segmented records for unformatted sequential access to disk or raw magnetic tape files.

Files containing segmented records can be accessed only by unformatted sequential data transfer statements.

If an output statement does not specify a full record for a file containing fixed-length records, the following occurs:

- In formatted files, the record is filled with blanks
- In unformatted files, the record is filled with zeros

See Also
- OPEN Statement Overview

Building Applications for details on record types and file organization

OPEN: SHARE Specifier

The SHARE specifier indicates whether file locking is implemented while the unit is open. It takes the following form:

SHARE = shr

shr

Is a scalar default character expression.

On Windows* systems, this expression evaluates to one of the following values:

- 'DENYRW' Indicates deny-read/write mode. No other process can open the file.
- 'DENYWR' Indicates deny-write mode. No process can open the file with write access.
- 'DENYRD' Indicates deny-read mode. No process can open the file with read access.
Indicates deny-none mode. Any process can open the file in any mode.

On Linux* and Mac OS* X systems, this expression evaluates to one of the following values:

- **'DENYRW'** Indicates exclusive access for cooperating processes.
- **'DENYNONE'** Indicates shared access for cooperating processes.

On Windows systems, the default is 'DENYWR'. However, if you specify compiler option fpscomp general or the SHARED specifier, the default is 'DENYNONE'.

On Linux and Mac OS X systems, no restrictions are applied to file opening if you do not use a locking mechanism.

'COMPAT' is accepted for compatibility with previous versions. It is equivalent to 'DENYNONE'.

Use the ACCESS specifier in an INQUIRE statement to determine the access permission for a file.

Be careful not to permit other users to perform operations that might cause problems. For example, if you open a file intending only to read from it, and want no other user to write to it while you have it open, you could open it with ACTION='READ' and SHARE='DENYRW'. Other users would not be able to open it with ACTION='WRITE' and change the file.

Suppose you want several users to read a file, and you want to make sure no user updates the file while anyone is reading it. First, determine what type of access to the file you want to allow the original user. Because you want the initial user to read the file only, that user should open the file with ACTION='READ'. Next, determine what type of access the initial user should allow other users; in this case, other users should be able only to read the file. The first user should open the file with SHARE='DENYRW'. Other users can also open the same file with ACTION='READ' and SHARE='DENYRW'.

**See Also**
- OPEN Statement Overview
- fpscomp compiler option

Building Applications for details about limitations on record access
OPEN: SHARED Specifier

The SHARED specifier indicates that the file is connected for shared access by more than one program executing simultaneously. It takes the following form:

```
SHARED
```

On Linux* and Mac OS* X systems, shared access is the default for the Fortran I/O system. On Windows* systems, it is the default if SHARED or compiler option fpscomp general is specified.

See Also

- OPEN Statement Overview
- fpscomp general compiler option

Building Applications for details on file sharing

OPEN: STATUS Specifier

The STATUS specifier indicates the status of a file when it is opened. It takes the following form:

```
STATUS = sta
```

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'OLD'</td>
<td>Indicates an existing file.</td>
</tr>
<tr>
<td>'NEW'</td>
<td>Indicates a new file; if the file already exists, an error occurs. Once the file is created, its status changes to 'OLD'.</td>
</tr>
<tr>
<td>'SCRATCH'</td>
<td>Indicates a new file that is unnamed (called a scratch file). When the file is closed or the program terminates, the scratch file is deleted.</td>
</tr>
<tr>
<td>'REPLACE'</td>
<td>Indicates the file replaces another. If the file to be replaced exists, it is deleted and a new file is created with the same name.</td>
</tr>
</tbody>
</table>
If the file to be replaced does not exist, a new file is created and its status changes to 'OLD'.

'UNKNOWN'

Indicates the file may or may not exist. If the file does not exist, a new file is created and its status changes to 'OLD'.

Scratch files go into a temporary directory and are visible while they are open. Scratch files are deleted when the unit is closed or when the program terminates normally, whichever occurs first.

To specify the path for scratch files, you can use one of the following environment variables:

- On Windows* OS: FORT_TMPDIR, TMP, or TEMP, searched in that order
- On Linux* OS and Mac OS X: FORT_TMPDIR or TMPDIR, searched in that order

If no environment variable is defined, the default is the current directory.

The default is 'UNKNOWN'. This is also the default if you implicitly open a file by using WRITE. However, if you implicitly open a file using READ, the default is 'OLD'. If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'NEW'.

**NOTE.** The STATUS specifier can also appear in CLOSE statements to indicate the file's status after it is closed. However, in CLOSE statements the STATUS values are the same as those listed for the DISPOSE specifier.

**See Also**
- OPEN Statement Overview
- f66 compiler option

**OPEN: TITLE Specifier (W*32, W*64)**

The TITLE specifier indicates the name of a child window in a QuickWin application. It takes the following form:

```
TITLE = name
```

*name* is a character expression.

If TITLE is specified in a non-Quickwin application, a run-time error occurs.
See Also

• OPEN Statement Overview

Building Applications: Using QuickWin Overview

OPEN: TYPE Specifier

TYPE is a nonstandard synonym for STATUS.

OPEN: USEROPEN Specifier

The USEROPEN specifier lets you pass control to a routine that directly opens a file. The file can use system calls or library routines to establish a special context that changes the effect of subsequent Fortran I/O statements.

The USEROPEN specifier takes the following form:

```
USEROPEN = function-name
```

*function-name* is the name of an external function; it must be of type INTEGER(4) (INTEGER*4).

The external function can be written in Fortran, C, or other languages.

If the function is written in Fortran, do not execute a Fortran OPEN statement to open the file named in USEROPEN.

The Intel® Fortran Run-time Library (RTL) I/O support routines call the function named in USEROPEN in place of the system calls normally used when the file is first opened for I/O.

On Windows* systems, the Fortran RTL normally calls CreateFile() to open a file. When USEROPEN is specified, the called function opens the file (or pipe, etc.) by using CreateFile() and returns the handle of the file (return value from CreateFile()) when it returns control to the calling Fortran program.

On Linux* and Mac OS* X systems, the Fortran RTL normally calls the open function to open a file. When USEROPEN is specified, the called function opens the file by calling open and returns the file descriptor of the file when it returns control to the calling Fortran program.

When opening the file, the called function usually specifies options different from those provided by a normal Fortran OPEN statement.

Examples

The following shows an example on Linux and Mac OS X systems and an example on Windows systems.
Example on Linux and Mac OS X systems:

```fortran
PROGRAM UserOpenMain
IMPLICIT NONE
EXTERNAL UOPEN
INTEGER(4) UOPEN
CHARACTER(10) :: FileName="UOPEN.DAT"
INTEGER :: IOS
CHARACTER(255):: InqFullName
CHARACTER(100):: InqFileName
INTEGER :: InqLun
CHARACTER(30) :: WriteOutBuffer="Write_One_Record_to_the_File. 
CHARACTER(30) :: ReadInBuffer ="??????????????????????????????"

110 FORMAT( X,"FortranMain: ",A," Created (iostat=",I0,")")
115 FORMAT( X,"FortranMain: ",A,": Creation Failed (iostat=",I0,")")
120 FORMAT( X,"FortranMain: ",A,": ERROR: INQUIRE Returned Wrong FileName")
130 FORMAT( X,"FortranMain: ",A,": ERROR: ReadIn and WriteOut Buffers Do Not Match")
WRITE(*,'(X,"FortranMain: Test the USEROPEN Facility of Open")')
OPEN(UNIT=10,FILE='UOPEN.DAT',STATUS='REPLACE',USEROPEN=UOPEN, &
   IOSTAT=ios, ACTION='READWRITE')

! When the OPEN statement is executed, the uopen_ function receives control.
! The uopen_ function opens the file by calling open(), and subsequently
! returns control with the handle returned by open().
IF (IOS .EQ. 0) THEN
  WRITE(*,110) TRIM(FileName), IOS
  INQUIRE(10, NAME=InqFullName)
  CALL ParseForFileName(InqFullName,InqFileName)
  IF (InqFileName .NE. FileName) THEN
```

(Continues on the next page)
WRITE(*,120) TRIM(FileName)
END IF
ELSE
WRITE(*,115) TRIM(FileName), IOS
GOTO 9999
END IF
WRITE(10,*) WriteOutBuffer
REWIND(10)
READ(10,*) ReadInBuffer
IF (ReadinBuffer .NE. WriteOutbuffer) THEN
WRITE(*,130) TRIM(FileName)
END IF
CLOSE(10)
WRITE(*,'(X,"FortranMain: Test of USEROPEN Completed")')
9999 CONTINUE
END

!---------------------------------------------------------------
! SUBROUTINE: ParseForFileName
! Takes a full pathname and returns the filename
! with its extension.
SUBROUTINE ParseForFileName(FullName, FileName)
    CHARACTER(255):: FullName
    CHARACTER(255):: FileName
    INTEGER :: P
    P = INDEX(FullName,'/','',.TRUE.)
    FileName = FullName(P+1:)
END

//
// File: UserOpen_Sub.c
//
// This routine opens a file using data passed from the Intel(c) Fortran OPEN statement.
//
#include <stdio.h>
#include <stdlib.h>
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <sys/file.h>
#include <errno.h>

int uopen_ ( char *file_name, /* access read: name of the file to open (null terminated) */
            int *open_flags, /* access read: READ/WRITE, see file.h or open(2) */
            int *create_mode, /* access read: set if the file is to be created */
            int *unit_num, /* access read: logical unit number to be opened */
            int filenam_len ) /* access read: number of characters in file_name */
{
    /*
    ** The returned value is the following:
** value >= 0 is a valid file descriptor
** value < 0 is an error
*/
int return_value;
printf(" %s: Opening FILENAME = %s\n", __FILE__, file_name);
printf(" %s: open_flags = 0x%8.8x\n", __FILE__, *open_flags);
if ( *open_flags & O_CREAT ) {
    printf(" %s: the file is being created, create_mode = 0x%8.8x\n", __FILE__, *create_mode);
}
printf(" %s: open() ", __FILE__);  
return_value = open(file_name, *open_flags, *create_mode);
if (return_value < 0) {
    printf("FAILED.\n");
} else {  
    printf("SUCCEEDED.\n");
}
return (return_value);
} /* end of uopen_() */

** Example on Windows systems:**

In the calling Fortran program, the function named in USEROPEN must first be declared in an EXTERNAL statement. For example, the following Fortran code might be used to call the USEROPEN procedure UOPEN:

```
IMPLICIT INTEGER (A-Z)
EXTERNAL UOPEN
...
OPEN(UNIT=10,FILE='UOPEN.DAT',STATUS='NEW',USEROPEN=UOPEN)
```

When the OPEN statement is executed, the UOPEN function receives control. The function opens the file by calling CreateFile(), performs whatever operations were specified, and subsequently returns control (with the handle returned by CreateFile()) to the calling Fortran program.
Here is what the UOPEN function might look like:

```fortran
INTEGER FUNCTION UOPEN( FILENAME, &
  DESIRED_ACCESS, &
  SHARE_MODE, &
  A_NULL, &
  CREATE_DISP, &
  FLAGS_ATTR, &
  B_NULL, &
  UNIT, &
  FLEN )

!DEC$ ATTRIBUTES C, ALIAS:'_UOPEN' :: UOPEN
!DEC$ ATTRIBUTES REFERENCE :: FILENAME
!DEC$ ATTRIBUTES REFERENCE :: DESIRED_ACCESS
!DEC$ ATTRIBUTES REFERENCE :: SHARE_MODE
!DEC$ ATTRIBUTES REFERENCE :: CREATE_DISP
!DEC$ ATTRIBUTES REFERENCE :: FLAGS_ATTR
!DEC$ ATTRIBUTES REFERENCE :: UNIT

USE IFWIN
IMPLICIT INTEGER (A-Z)
CHARACTER*(FLEN) FILENAME

TYPE(T_SECURITY_ATTRIBUTES), POINTER :: NULL_SEC_ATTR

! Set the FILE_FLAG_WRITE_THROUGH bit in the flag attributes to CreateFile( )
! (for whatever reason)
FLAGS_ATTR = FLAGS_ATTR + FILE_FLAG_WRITE_THROUGH

! Do the CreateFile( ) call and return the status to the Fortran rtl
STS = CreateFile( FILENAME, &
  DESIRED_ACCESS, &
  SHARE_MODE, &
  NULL_SEC_ATTR, &

2153
```
The UOPEN function is declared to use the cdecl calling convention, so it matches the Fortran rtl
declaration of a useropen routine.

The following function definition and arguments are passed from the Intel Fortran Run-time Library
to the function named in USEROPEN:

```fortran
INTEGER FUNCTION UOPEN( FILENAME, 
  DESIRED_ACCESS, &
  SHARE_MODE, &
  A_NULL, &
  CREATE_DISP, &
  FLAGS_ATTR, &
  B_NULL, &
  UNIT, &
  FLEN )

!DEC$ ATTRIBUTES C, ALIAS:'_UOPEN' :: UOPEN
!DEC$ ATTRIBUTES REFERENCE :: DESIRED_ACCESS
!DEC$ ATTRIBUTES REFERENCE :: SHARE_MODE
!DEC$ ATTRIBUTES REFERENCE :: CREATE_DISP
!DEC$ ATTRIBUTES REFERENCE :: FLAGS_ATTR
!DEC$ ATTRIBUTES REFERENCE :: UNIT
```

The first 7 arguments correspond to the CreateFile() api arguments. The value of these arguments
is set according the caller’s OPEN() arguments:

- **FILENAME**
  Is the address of a null terminated character string that is the name of the file.

- **DESIRED_ACCESS**
  Is the desired access (read-write) mode passed by reference.
SHARE_MODE Is the file sharing mode passed by reference.
A_NULL Is always null. The Fortran runtime library always passes a NULL for the pointer to a SECURITY_ATTRIBUTES structure in its CreateFile() call.
CREATE_DISP Is the creation disposition specifying what action to take on files that exist, and what action to take on files that do not exist. It is passed by reference.
FLAGS_ATTR Specifies the file attributes and flags for the file. It is passed by reference.
B_NULL Is always null. The Fortran runtime library always passes a NULL for the handle to a template file in it's CreateFile() call.

The last 2 arguments are the Fortran unit number and length of the file name:
UNIT Is the Fortran unit number on which this OPEN is being done. It is passed by reference.
FLEN Is the length of the file name, not counting the terminating null, and passed by value.

REWIND Statement Overview
The REWIND statement positions a sequential or direct access file at the beginning of the file (the initial point). For more information, see REWIND.

WAIT Statement Overview
The WAIT statement performs a wait operation for specified pending asynchronous data transfer operations. For more information, see WAIT.
Compilation Control Lines and Statements

In addition to specifying options on the compiler command line, you can specify the following lines and statements in a program unit to influence compilation:

- **The INCLUDE Line**
  Incorporates external source code into programs.

- **The OPTIONS Statement**
  Sets options usually specified in the compiler command line. OPTIONS statement settings override command line options.
Directive Enhanced Compilation

Directive enhanced compilation is performed by using compiler directives. Compiler directives are special commands that let you perform various tasks during compilation. They are similar to compiler options, but can provide more control within your program.

Compiler directives are preceded by a special prefix that identifies them to the compiler.

**Syntax Rules for Compiler Directives**

The following syntax rules apply to all general and OpenMP Fortran compiler directives. You must follow these rules precisely to compile your program properly and obtain meaningful results.

A directive prefix (tag) takes one of the following forms:

- General compiler directives: `cDEC$
- OpenMP Fortran compiler directives:

  - Is one of the following: C (or c), !, or *.

The following prefix forms can be used in place of `cDEC$:

- `cDIR$ or `!MS$.

The following are source form rules for directive prefixes:

- In fixed and tab source forms, prefixes begin with C (or c), *, or !.
  
  The prefix must appear in columns 1 through 5; column 6 must be a blank or a tab. From column 7 on, blanks are insignificant, so the directive can be positioned anywhere on the line after column 6.

- In free source form, prefixes begin with !.
  
  The prefix can appear in any column, but it cannot be preceded by any nonblank, nontab characters on the same line.

- In all source forms, directives spelled with two keywords can be separated by an optional space; for example, "LOOP COUNT" and "LOOPCOUNT" are both valid spellings for the same directive. However, when a directive name is preceded by the prefix "NO", this is not considered to be two keywords. For example, "NO PREFETCH" is not a valid spelling; the only valid spelling for this directive is "NOPREFETCH".

A compiler directive ends in column 72 (or column 132, if compiler option extend-source is specified).

3 Except for prefix `!MS$
General compiler directives cannot be continued. OpenMP Fortran directives can be continued. A comment beginning with an ! can follow a compiler directive on the same line. Additional Fortran statements (or directives) cannot appear on the same line as the compiler directive. Compiler directives cannot appear within a continued Fortran statement. Blank common used in a compiler directive is specified by two slashes (/ /). If the source line starts with a valid directive prefix but the directive is not recognized, the compiler displays an informational message and ignores the line.

**General Compiler Directives**

Intel® Fortran provides several general-purpose compiler directives to perform tasks during compilation. You do not need to specify a compiler option to enable general directives.

The following general compiler directives are available:

- **ALIAS**
  Specifies an alternate external name to be used when referring to external subprograms.
- **ASSUME_ALIGNED**
  Specifies that an entity in memory is aligned.
- **ATTRIBUTES**
  Specifies properties for data objects and procedures.
- **DECLARE and NODECLARE**
  Generates or disables warnings for variables that have been used but not declared.
- **DEFINE and UNDEFINE**
  Defines (or undefines) a symbolic variable whose existence (or value) can be tested during conditional compilation.
- **DISTRIBUTE POINT**
  Specifies distribution for a DO loop.
- **FIXEDFORM LINESIZE**
  Sets the line length for fixed-form source code.
- **FREEFORM and NOFREEFORM**
  Specifies free-format or fixed-format source code.
- **IDENT**
Specifies an identifier for an object module.

- **IF and IF DEFINED**
  Specifies a conditional compilation construct.

- **INTEGER**
  Specifies the default integer kind.

- **IVDEP**
  Assists the compiler's dependence analysis of iterative DO loops.

- **LOOP COUNT**
  Specifies the loop count for a DO loop; this assists the optimizer.

- **MEMORYTOUCH**
  Ensures that a specific memory location is updated dynamically.

- **MEMREF_CONTROL**
  Lets you provide cache hints on prefetches, loads, and stores.

- **MESSAGE**
  Specifies a character string to be sent to the standard output device during the first compiler pass.

- **OBJCOMMENT**
  Specifies a library search path in an object file.

- **OPTIMIZE and NOOPTIMIZE**
  Enables or disables optimizations.

- **OPTIONS**
  Affects data alignment and warnings about data alignment.

- **PACK**
  Specifies the memory starting addresses of derived-type items.

- **PARALLEL and NOPARALLEL**
  Facilitates or prevents auto-parallelization for the immediately following DO loop.

- **PREFETCH and NOPREFETCH**
  Enables or disables a data prefetch from memory.

- **PSECT**
  Modifies certain characteristics of a common block.

- **REAL**
Specifies the default real kind.

- **STRICT and NOSTRICT**
  Disables or enables language features not found in the language standard specified on the command line (Fortran 2003, Fortran 95, or Fortran 90).

- **SWP and NOSWP**
  Enables or disables software pipelining for a DO loop.

- **UNROLL and NOUNROLL**
  Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop.

- **UNROLL_AND_JAM and NOUNROLL_AND_JAM**
  Enables or disables loop unrolling and jamming.

- **VECTOR ALIGNED and VECTOR UNALIGNED**
  Specifies that all data is aligned or no data is aligned in a DO loop.

- **VECTOR ALWAYS and NOVECTOR**
  Enables or disables vectorization of a DO loop.

- **VECTOR TEMPORAL and VECTOR NONTEMPORAL**
  Controls how the 'stores' of register contents to storage are performed (streaming versus non-streaming).

### Rules for General Directives that Affect DO Loops

This table lists the general directives that affect DO loops:

<table>
<thead>
<tr>
<th>Directive</th>
<th>Unroll &amp; Jam</th>
<th>Vector Aligned</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distribute Point</td>
<td>Nounroll and Jam</td>
<td></td>
</tr>
<tr>
<td>Ivdep</td>
<td>Novector</td>
<td>Vector Always</td>
</tr>
<tr>
<td>Loop Count</td>
<td>Parallel</td>
<td>Vector NonTemporal</td>
</tr>
<tr>
<td>Not Parallel</td>
<td>Prefetch</td>
<td>Vector Novector</td>
</tr>
<tr>
<td>Not Prefetch</td>
<td>Swp</td>
<td>Vector Temporal</td>
</tr>
<tr>
<td>Not Swp</td>
<td>Unroll</td>
<td>Vector Unaligned</td>
</tr>
<tr>
<td>Nounroll</td>
<td>Unroll and Jam</td>
<td></td>
</tr>
</tbody>
</table>

1 i32, i64em
The following rules apply to all of these directives:

- The directive must precede the DO statement for each DO loop it affects.
- No source code lines, other than the following, can be placed between the directive statement and the DO statement:
  - One of the other general directives that affect DO loops
  - An OpenMP* Fortran PARALLEL DO directive
  - Comment lines
  - Blank lines

Other rules may apply to these directives. For more information, see the description of each directive.

Rules for Loop Directives that Affect Array Assignment Statements

When certain loop directives precede an array assignment statement, they affect the implicit loops that are generated by the compiler.

The following loop directives can affect array assignment statements:

<table>
<thead>
<tr>
<th>Directive</th>
<th>NOVECTOR(^1)</th>
<th>VECTOR ALIGNED</th>
</tr>
</thead>
<tbody>
<tr>
<td>IVDEP</td>
<td>PARALLEL</td>
<td>VECTOR ALWAYS</td>
</tr>
<tr>
<td>LOOP COUNT</td>
<td>PREFETCH</td>
<td>VECTOR NONTEMPORAL(^1)</td>
</tr>
<tr>
<td>NOPARALLEL</td>
<td>SWP(^2)</td>
<td>VECTOR NOVECTOR(^1)</td>
</tr>
<tr>
<td>NOPREFETCH</td>
<td>UNROLL</td>
<td>VECTOR TEMPORAL(^1)</td>
</tr>
<tr>
<td>NOSWP(^2)</td>
<td>UNROLL_AND_JAM</td>
<td>VECTOR UNALIGNED</td>
</tr>
</tbody>
</table>

\(^1\) i32, i64em
\(^2\) i64 only

Only one of the above directives can precede the array assignment statement (one-dimensional-array = expression) to affect it.

Other rules may apply to these directives. For more information, see the description of each directive.
Examples

Consider the following:

```fortran
REAL A(10), B(10)

!DEC$ IVDEP
A = B + 3
```

This has the same effect as writing the following explicit loop:

```fortran
!DEC$ IVDEP
DO I = 1, 10
    A (I) = B (I) + 3
END DO
```

**OpenMP® Fortran Compiler Directives**

Intel® Fortran provides OpenMP® Fortran compiler directives that comply with OpenMP Fortran Application Program Interface (API) specification Version 1.1 and most of Version 2.0.

To use these directives, you must specify compiler option `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows).

This section discusses data scope attribute clauses, conditional compilation rules, nesting and binding rules, and the following directives:

- **ATOMIC directive**
  Specifies that a specific memory location is to be updated dynamically.

- **BARRIER directive**
  Synchronizes all the threads in a team.

- **CRITICAL directive**
  Restricts access for a block of code to only one thread at a time.

- **DO directive**
  Specifies that the iterations of the immediately following DO loop must be executed in parallel.

- **FLUSH directive**
  Specifies synchronization points where the implementation must have a consistent view of memory.
• MASTER directive
  Specifies a block of code to be executed by the master thread of the team.
• ORDERED directive
  Specifies a block of code to be executed sequentially.
• PARALLEL directive
  Defines a parallel region.
• PARALLEL DO directive
  Defines a parallel region that contains a single DO directive.
• PARALLEL SECTIONS directive
  Defines a parallel region that contains SECTIONS directives.
• PARALLEL WORKSHARE directive
  Defines a parallel region that contains a single WORKSHARE directive.
• SECTIONS directive
  Specifies a block of code to be divided among threads in a team (a worksharing area).
• SINGLE directive
  Specifies a block of code to be executed by only one thread in a team.
• TASK directive
  Defines a task region.
• TASKWAIT directive
  Specifies a wait on the completion of child tasks generated since the beginning of the current task.
• THREADPRIVATE directive
  Makes named common blocks private to a thread but global within the thread.
• WORKSHARE directive
  Divides the work of executing a block of statements or constructs into separate units.

The OpenMP parallel directives can be grouped into the categories shown in the following table:

**Table 677: Categories of OpenMP Fortran Parallel Directives**

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parallel region</td>
<td>Defines a parallel region: PARALLEL</td>
</tr>
<tr>
<td>Task region</td>
<td>Defines a task region: TASK</td>
</tr>
<tr>
<td>Category</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Work-sharing</td>
<td>Divide the execution of the enclosed block of code among the members of the team that encounter it: DO and SECTIONS</td>
</tr>
<tr>
<td>Combined parallel work-sharing</td>
<td>Shortcut for denoting a parallel region that contains only one work-sharing construct: PARALLEL DO and PARALLEL SECTIONS</td>
</tr>
<tr>
<td>Synchronization</td>
<td>Provide various aspects of synchronization; for example, access to a block of code, or execution order of statements within a block of code: ATOMIC, BARRIER, CRITICAL, FLUSH, MASTER, ORDERED, and TASKWAIT.</td>
</tr>
<tr>
<td>Data Environment</td>
<td>Control the data environment during the execution of parallel constructs: THREADPRIVATE</td>
</tr>
</tbody>
</table>

Note that certain general directives and rules can affect DO loops. For more information, see Rules for General Directives that Affect DO Loops.

**Data Scope Attribute Clauses**

Some of the OpenMP* Fortran directives have clauses (or options) you can specify to control the scope attributes of variables for the duration of the directive.

Other clauses (or options) are available for some OpenMP Fortran directives. For more information, see each directive description.

Conditional Compilation Rules

The OpenMP® Fortran API lets you conditionally compile Intel® Fortran statements if you use the appropriate directive prefix.

The prefix depends on which source form you are using, although !$ is valid in all forms.

The prefix must be followed by a valid Intel Fortran statement on the same line.

Free Source Form

The free source form conditional compilation prefix is !$. This prefix can appear in any column as long as it is preceded only by white space. It must appear as a single word with no intervening white space. Free-form source rules apply to the directive line.

Initial lines must have a space after the prefix. Continued lines must have an ampersand as the last nonblank character on the line. Continuation lines can have an ampersand after the prefix with optional white space before and after the ampersand.

Fixed Source Form

For fixed source form programs, the conditional compilation prefix is one of the following: !$, C$ (or c$), or *$.

The prefix must start in column one and appear as a single string with no intervening white space. Fixed-form source rules apply to the directive line.

Initial lines must have a space or zero in column six, and continuation lines must have a character other than a space or zero in column six. For example, the following forms for specifying conditional compilation are equivalent:

```
c23456789
!$ IAM = OMP_GET_THREAD_NUM( ) +
!$ * INDEX
#ififdef _OPENMP
IAM = OMP_GET_THREAD_NUM( ) +
* INDEX
#endif
```
Nesting and Binding Rules

This section describes the dynamic nesting and binding rules for OpenMP* Fortran API directives.

Binding Rules

The following rules apply to dynamic binding:

- The DO, SECTIONS, SINGLE, MASTER, and BARRIER directives bind to the dynamically enclosing PARALLEL directive, if one exists.
- The ORDERED directive binds to the dynamically enclosing DO directive.
- The ATOMIC directive enforces exclusive access with respect to ATOMIC directives in all threads, not just the current team.
- The CRITICAL directive enforces exclusive access with respect to CRITICAL directives in all threads, not just the current team.
- A directive can never bind to any directive outside the closest enclosing PARALLEL directive.

Nesting Rules

The following rules apply to dynamic nesting:

- A PARALLEL directive dynamically inside another PARALLEL directive logically establishes a new team, which is composed of only the current thread unless nested parallelism is enabled.
- DO, SECTIONS, and SINGLE directives that bind to the same PARALLEL directive are not allowed to be nested one inside the other.
- DO, SECTIONS, and SINGLE directives are not permitted in the dynamic extent of CRITICAL and MASTER directives.
- BARRIER directives are not permitted in the dynamic extent of DO, SECTIONS, SINGLE, MASTER, and CRITICAL directives.
- MASTER directives are not permitted in the dynamic extent of DO, SECTIONS, and SINGLE directives.
- ORDERED sections are not allowed in the dynamic extent of CRITICAL sections.
- Any directive set that is legal when executed dynamically inside a PARALLEL region is also legal when executed outside a parallel region. When executed dynamically outside a user-specified parallel region, the directive is executed with respect to a team composed of only the master thread.
Examples

The following example shows nested PARALLEL regions:

```
c$OMP PARALLEL DEFAULT(SHARED)
  c$OMP DO
    DO I =1, N
      c$OMP PARALLEL SHARED(I,N)
      c$OMP DO
        DO J =1, N
          CALL WORK(I,J)
        END DO
      END DO
  END DO
  c$OMP END PARALLEL
```

Note that the inner and outer DO directives bind to different PARALLEL regions.
The following example shows a variation of the preceding example:

```fortran
BEGIN
    c$OMP PARALLEL DEFAULT(SHARED)
    c$OMP DO
        DO I = 1, N
            CALL SOME_WORK(I,N)
        END DO
    c$OMP END PARALLEL
    ...
    SUBROUTINE SOME_WORK(I,N)
    c$OMP PARALLEL DEFAULT(SHARED)
    c$OMP DO
        DO J = 1, N
            CALL WORK(I,J)
        END DO
    c$OMP END PARALLEL
    RETURN
END
```

```fortran
2170
```
Scope and Association

Program entities are identified by names, labels, input/output unit numbers, operator symbols, or assignment symbols. For example, a variable, a derived type, or a subroutine is identified by its name. Scope refers to the area in which a name is recognized. A scoping unit is the program or part of a program in which a name is defined or known. It can be any of the following:

- An entire executable program
- A single scoping unit
- A single statement (or part of a statement)

The region of the program in which a name is known and accessible is referred to as the scope of that name. These different scopes allow the same name to be used for different things in different regions of the program.

Association is the language concept that allows different names to refer to the same entity in a particular region of a program.

**Scope**

Program entities have the following kinds of scope (as shown in the table below):

- **Global**
  Entities that are accessible throughout an executable program. The name of a global entity must be unique. It cannot be used to identify any other global entity in the same executable program.

- **Scoping unit (Local scope)**
  Entities that are declared within a scoping unit. These entities are local to that scoping unit. The names of local entities are divided into classes (see the table below).

  A **scoping unit** is one of the following:
  
  - A derived-type definition
  - A procedure interface body (excluding any derived-type definitions and interface bodies contained within it)
  - A program unit or subprogram (excluding any derived-type definitions, interface bodies, and subprograms contained within it)

  A scoping unit that immediately surrounds another scoping unit is called the host scoping unit. Named entities within the host scoping unit are accessible to the nested scoping unit by host association. (For information about host association, see Use and Host Association.)
Once an entity is declared in a scoping unit, its name can be used throughout that scoping unit. An entity declared in another scoping unit is a different entity even if it has the same name and properties.

Within a scoping unit, a local entity name that is not generic must be unique within its class. However, the name of a local entity in one class can be used to identify a local entity of another class.

Within a scoping unit, a generic name can be the same as any one of the procedure names in the interface block.

A component name has the same scope as the derived type of which it is a component. It can appear only within a component designator of a structure of that type.

For information on interactions between local and global names, see the table below.

- **Statement**

  Entities that are accessible only within a statement or part of a statement; such entities cannot be referenced in subsequent statements.

  The name of a statement entity can also be the name of a global or local entity in the same scoping unit; in this case, the name is interpreted within the statement as that of the statement entity.

</table>

1 Names of common blocks can also be used to identify local entities.
2 If an intrinsic procedure is not used in a scoping unit, its name can be used as a local entity within that scoping unit. For example, if intrinsic function COS is not used in a program unit, COS can be used as a local variable there.
3 The DO variable in an implied-DO list of an I/O list has local scope.
The scope of the assignment symbol (=) is global, but it can identify additional operations (see Defining Generic Assignment).

Scoping units can contain other scoping units. For example, the following shows six scoping units:

```fortran
MODULE MOD_1 ! Scoping unit 1
  ...
  CONTAINS ! Scoping unit 1
    FUNCTION FIRST ! Scoping unit 2
      TYPE NAME ! Scoping unit 3
        ...
        END TYPE NAME ! Scoping unit 3
      ...
      CONTAINS ! Scoping unit 2
        SUBROUTINE SUB_B ! Scoping unit 4
          TYPE PROCESS ! Scoping unit 5
            ...
            END TYPE PROCESS ! Scoping unit 5
          INTERFACE ! Scoping unit 5
            SUBROUTINE SUB_A ! Scoping unit 6
              ...
              END SUBROUTINE SUB_A ! Scoping unit 6
          END INTERFACE ! Scoping unit 5
      END SUBROUTINE SUB_B ! Scoping unit 4
    END FUNCTION FIRST ! Scoping unit 2
  END MODULE ! Scoping unit 1
```

Unambiguous Generic Procedure References

When a generic procedure reference is made, a specific procedure is invoked. If the following rules are used, the generic reference will be unambiguous:

- Within a scoping unit, two procedures that have the same generic name must both be subroutines (or both be functions). One of the procedures must have a nonoptional dummy argument that is one of the following:
  - Not present by position or argument keyword in the other argument list
  - Is present, but has different type and kind parameters, or rank

- Within a scoping unit, two procedures that have the same generic operator must both have the same number of arguments or both define assignment. One of the procedures must have a dummy argument that corresponds by position in the argument list to a dummy argument of the other procedure that has a different type and kind parameters, or rank.

When an interface block extends an intrinsic procedure, operator, or assignment, the rules apply as if the intrinsic consists of a collection of specific procedures, one for each allowed set of arguments.

When a generic procedure is accessed from a module, the rules apply to all the specific versions, even if some of them are inaccessible by their specific names.

- Scope and Association
- Defining Generic Names for Procedures

Resolving Procedure References

The procedure name in a procedure reference is either established to be generic or specific, or is not established. The rules for resolving a procedure reference differ depending on whether the procedure is established and how it is established.
This section discusses the following topics:

- References to Generic Names
- References to Specific Names
- References to Nonestablished Names

**References to Generic Names**

Within a scoping unit, a procedure name is established to be generic if any of the following is true:

- The scoping unit contains an interface block with that procedure name.
- The procedure name matches the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
- The procedure name is established to be generic in a module, and the scoping unit contains a USE statement making that procedure name accessible.
- The scoping unit contains no declarations for that procedure name, but the procedure name is established to be generic in a host scoping unit.

To resolve a reference to a procedure name established to be generic, the following rules are used in the order shown:

1. If an interface block with that procedure name appears in one of the following, the reference is to the specific procedure providing that interface:
   - The scoping unit that contains the reference
   - A module made accessible by a USE statement in the scoping unit

   The reference must be consistent with one of the specific interfaces of the interface block.

2. If the procedure name is specified with the INTRINSIC attribute in one of the following, the reference is to that intrinsic procedure:
   - The same scoping unit
   - A module made accessible by a USE statement in the scoping unit

   The reference must be consistent with the interface of that intrinsic procedure.

3. If the following is true, the reference is resolved by applying rules 1 and 2 to the host scoping unit:
   - The procedure name is established to be generic in the host scoping unit
   - There is agreement between the scoping unit and the host scoping unit as to whether the procedure is a function or subroutine name.
4. If none of the preceding rules apply, the reference must be to the generic intrinsic procedure with that name. The reference must be consistent with the interface of that intrinsic procedure.
Examples

The following example shows how a module can define three separate procedures, and a main program give them a generic name DUP through an interface block. Although the main program calls all three by the generic name, there is no ambiguity since the arguments are of different data types, and DUP is a function rather than a subroutine. The module UN_MOD must give each procedure a different name.

```
MODULE UN_MOD
!
CONTAINS
  subroutine dup1(x,y)
    real x,y
    print *, ' Real arguments', x, y
  end subroutine dup1
  subroutine dup2(m,n)
    integer m,n
    print *, ' Integer arguments', m, n
  end subroutine dup2
  character function dup3 (z)
    character(len=2) z
    dup3 = 'String argument '// z
  end function dup3
END MODULE

program unclear
!
! shows how to use generic procedure references
USE UN_MOD
INTERFACE DUP
  MODULE PROCEDURE dup1, dup2, dup3
END INTERFACE
```
real a, b
integer c, d
character (len=2) state
a = 1.5
b = 2.32
c = 5
d = 47
state = 'WA'
call dup(a, b)
call dup(c, d)
print *, dup(state) ! actual output is 'S' only
END

Note that the function DUP3 only prints one character, since module UN_MOD specifies no length parameter for the function result.

If the dummy arguments x and y for DUP were declared as integers instead of reals, then any calls to DUP would be ambiguous. If this is the case, a compile-time error results.

The subroutine definitions, DUP1, DUP2, and DUP3, must have different names. The generic name is specified in the first line of the interface block, and in the example is DUP.

References to Specific Names

In a scoping unit, a procedure name is established to be specific if it is not established to be generic and any of the following is true:

- The scoping unit contains an interface body with that procedure name.
- The scoping unit contains an internal procedure, module procedure, or statement function with that procedure name.
- The procedure name is the same as the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
- The procedure name is specified with the EXTERNAL attribute in that scoping unit.
- The procedure name is established to be specific in a module, and the scoping unit contains a USE statement making that procedure name accessible.
- The scoping unit contains no declarations for that procedure name, but the procedure name is established to be specific in a host scoping unit.
To resolve a reference to a procedure name established to be specific, the following rules are used in the order shown:

1. If either of the following is true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   a. The scoping unit is a subprogram, and it contains an interface body with that procedure name.
   b. The procedure name has been declared EXTERNAL, and the procedure name is a dummy argument of that subprogram.

   The procedure invoked by the reference is the one supplied as the corresponding actual argument.

2. If the scoping unit contains an interface body or the procedure name has been declared EXTERNAL, and Rule 1 does not apply, the reference is to an external procedure with that name.

3. If the scoping unit contains an internal procedure or statement function with that procedure name, the reference is to that entity.

4. If the procedure name has been declared INTRINSIC in the scoping unit, the reference is to the intrinsic procedure with that name.

5. If the scoping unit contains a USE statement that makes the name of a module procedure accessible, the reference is to that procedure. (The USE statement allows renaming, so the name referenced may differ from the name of the module procedure.)

6. If none of the preceding rules apply, the reference is resolved by applying these rules to the host scoping unit.

References to Nonestablished Names

In a scoping unit, a procedure name is not established if it is not determined to be generic or specific.

To resolve a reference to a procedure name that is not established, the following rules are used in the order shown:

1. If both of the following are true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   a. The scoping unit is a subprogram.
   b. The procedure name is a dummy argument of that subprogram.

   The procedure invoked by the reference is the one supplied as the corresponding actual argument.
2. If both of the following are true, the procedure is an intrinsic procedure and the reference is to that intrinsic procedure:
   
   a. The procedure name matches the name of an intrinsic procedure.
   
   b. There is agreement between the intrinsic procedure definition and the reference of the name as a function or subroutine.

3. If neither of the preceding rules apply, the reference is to an external procedure with that name.

Association

Association allows different program units to access the same value through different names. Entities are associated when each is associated with the same storage location.

There are three kinds of association:

- Name association
- Pointer association
- Storage association

The following example shows name, pointer, and storage association between an external program unit and an external procedure.
Example of Name, Pointer, and Storage Association

! Scoping Unit 1: An external program unit
REAL A, B(4)
REAL, POINTER :: M(:)
REAL, TARGET :: N(12)
COMMON /COM/...
EQUIVALENCE (A, B(1)) ! Storage association between A and B(1)
M => N ! Pointer association
CALL P (actual-arg,...)
...

! Scoping Unit 2: An external procedure
SUBROUTINE P (dummy-arg,...) ! Name and storage association between
! these arguments and the calling
! routine's arguments in scoping unit 1
COMMON /COM/... ! Storage association with common block COM
! in scoping unit 1
REAL Y
CALL Q (actual-arg,...)
CONTAINS
SUBROUTINE Q (dummy-arg,...) ! Name and storage association between
! these arguments and the calling
! routine's arguments in host procedure
! P (subprogram Q has host association
! with procedure P)
Y = 2.0*(Y-1.0) ! Name association with Y in host procedure P
...

Name Association

Name association allows an entity to be accessed from different scoping units by the same name or by different names. There are three types of name association: argument, use, and host.

Argument Association

Arguments are the values passed to and from functions and subroutines through calling program argument lists.

Execution of a procedure reference establishes argument association between an actual argument and its corresponding dummy argument. The name of a dummy argument can be different from the name of its associated actual argument (if any).

When the procedure completes execution, the argument association is terminated.

See Also
- Name Association
- Argument Association

Use and Host Association

Use association allows the entities in a module to be accessible to other scoping units. The mechanism for use association is the USE statement. The USE statement provides access to all public entities in the module, unless ONLY is specified. In this case, only the entities named in the ONLY list can be accessed.

Host association allows the entities in a host scoping unit to be accessible to an internal procedure, derived-type definition, or module procedure contained within the host. The accessed entities are known by the same name and have the same attributes as in the host. Entities that are local to a procedure are not accessible to its host.

Use or host association remains in effect throughout the execution of the executable program.

If an entity that is accessed by use association has the same nongeneric name as a host entity, the host entity is inaccessible. A name that appears in the scoping unit as an external name in an EXTERNAL statement is a global name, and any entity of the host that has this as its nongeneric name is inaccessible.

An interface body does not access named entities by host association, but it can access entities by use association.

If a procedure gains access to a pointer by host association, the association of the pointer with a target that is current at the time the procedure is invoked remains current within the procedure. This pointer association can be changed within the procedure. After execution of the procedure, the pointer association remains current, unless the execution caused the target to become undefined. If this occurs, the host associated pointer becomes undefined.
NOTE. Implicit declarations can cause problems for host association. It is recommended that you use IMPLICIT NONE in both the host and the contained procedure, and that you explicitly declare all entities.

When all entities are explicitly declared, local declarations override host declarations, and host declarations that are not overridden are available in the contained procedure.

Examples

The following example shows host and use association:

```fortran
MODULE SHARE_DATA
  REAL Y, Z
END MODULE

PROGRAM DEMO
  USE SHARE_DATA ! All entities in SHARE_DATA are available
  REAL B, Q ! through use association.
  ...
  CALL CONS (Y)
END PROGRAM DEMO

CONTAINS

SUBROUTINE CONS (Y) ! Y is a local entity (dummy argument).
  REAL C, Y
  ...
  Y = B + C + Q + Z ! B and Q are available through host association.
  ...
  ! C is a local entity, explicitly declared. Z
END SUBROUTINE CONS

END PROGRAM DEMO
```
The following example shows how a host and an internal procedure can use host-associated entities:

```fortran
program INTERNAL
    ! shows use of internal subroutine and CONTAINS statement
    real a,b,c
    call find
    print *, c
contains
    subroutine find
        read *, a,b
        c = sqrt(a**2 + b**2)
    end subroutine find
end
```

In this example, the variables `a`, `b`, and `c` are available to the internal subroutine `find` through host association. They do not have to be passed as arguments to the internal procedure. In fact, if they are, they become local variables to the subroutine and hide the variables declared in the host program. Conversely, the host program knows the value of `c`, when it returns from the internal subroutine that has defined `c`.

**See Also**
- Name Association
- USE statement
- Scope

**Pointer Association**

A pointer can be associated with a target. At different times during the execution of a program, a pointer can be undefined, associated with different targets, or be disassociated. The initial association status of a pointer is undefined. A pointer can become associated by the following:

- By pointer assignment (pointer => target)
  The target must be associated, or specified with the TARGET attribute. If the target is allocatable, it must be currently allocated.
- By allocation (successful execution of an ALLOCATE statement)
  The ALLOCATE statement must reference the pointer.
A pointer becomes disassociated if any of the following occur:

- The pointer is nullified by a NULLIFY statement.
- The pointer is deallocated by a DEALLOCATE statement.
- The pointer is assigned a disassociated pointer (or the NULL intrinsic function).

When a pointer is associated with a target, the definition status of the pointer is defined or undefined, depending on the definition status of the target. A target is undefined in the following cases:

- If it was never allocated
- If it is not deallocated through the pointer
- If a RETURN or END statement causes it to become undefined

If a pointer is associated with a definable target, the definition status of the pointer can be defined or undefined, according to the rules for a variable.

If the association status of a pointer is disassociated or undefined, the pointer must not be referenced or deallocated.

Whatever its association status, a pointer can always be nullified, allocated, or associated with a target. When a pointer is nullified, it is disassociated. When a pointer is allocated, it becomes associated, but is undefined. When a pointer is associated with a target, its association and definition status are determined by its target.

**See Also**

- Association
- Pointer assignments
- NULL intrinsic function
- Dynamic Allocation

**Storage Association**

*Storage association* is the association of two or more data objects. It occurs when two or more storage sequences share (or are aligned with) one or more storage units. Storage sequences are used to describe relationships among variables, common blocks, and result variables.

**Storage Units and Storage Sequence**

A *storage unit* is a fixed unit of physical memory allocated to certain data. A *storage sequence* is a sequence of storage units. The size of a storage sequence is the number of storage units in the storage sequence. A storage unit can be numeric, character, or unspecified.
A nonpointer scalar of type default real, integer, or logical occupies one numeric storage unit. A nonpointer scalar of type double precision real or default complex occupies two contiguous numeric storage units. In Intel® Fortran, one numeric storage unit corresponds to 4 bytes of memory.

A nonpointer scalar of type default character with character length 1 occupies one character storage unit. A nonpointer scalar of type default character with character length \( len \) occupies \( len \) contiguous character storage units. In Intel Fortran, one character storage unit corresponds to 1 byte of memory.

A nonpointer scalar of nondefault data type occupies a single unspecified storage unit. The number of bytes corresponding to the unspecified storage unit differs depending on the data type.

The following table lists the storage requirements (in bytes) for the intrinsic data types:

**Table 679: Data Type Storage Requirements**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Requirements (in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>2, 4, or 8 ¹</td>
</tr>
<tr>
<td>LOGICAL(1)</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(2)</td>
<td>2</td>
</tr>
<tr>
<td>LOGICAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>LOGICAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>INTEGER</td>
<td>2, 4, or 8 ¹</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>1</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>2</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>8</td>
</tr>
<tr>
<td>REAL</td>
<td>4, 8, or 16 ²</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>4</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>8</td>
</tr>
<tr>
<td>Data Type</td>
<td>Storage Requirements (in bytes)</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>8</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>8, 16, or 32 ^2</td>
</tr>
<tr>
<td>COMPLEX(4)</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(8)</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(16)</td>
<td>32</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>1</td>
</tr>
<tr>
<td>CHARACTER*len</td>
<td>len ^3</td>
</tr>
<tr>
<td>CHARACTER*(*)</td>
<td>assumed-length ^4</td>
</tr>
</tbody>
</table>

1 Depending on default integer, LOGICAL and INTEGER can have 2, 4, or 8 bytes. The default allocation is four bytes.

2 Depending on default real, REAL can have 4, 8, or 16 bytes and COMPLEX can have 8, 16, or 32 bytes. The default allocations are four bytes for REAL and eight bytes for COMPLEX.

3 The value of len is the number of characters specified. The largest valid value is 2**31-1 on IA-32 architecture; 2**63-1 on Intel® 64 architecture and IA-64 architecture. Negative values are treated as zero.

4 The assumed-length format *(*) applies to dummy arguments, PARAMETER statements, or character functions, and indicates that the length of the actual argument or function is used. (See Assumed-Length Character Arguments and Building Applications.)

A nonpointer scalar of sequence derived type occupies a sequence of storage sequences corresponding to the components of the structure, in the order they occur in the derived-type definition. (A sequence derived type has a SEQUENCE statement.)

A pointer occupies a single unspecified storage unit that is different from that of any nonpointer object and is different for each combination of type, type parameters, and rank.

The definition status and value of a data object affects the definition status and value of any storage-associated entity.
When two objects occupy the same storage sequence, they are totally storage-associated. When two objects occupy parts of the same storage sequence, they are partially associated. An EQUIVALENCE statement, a COMMON statement, or an ENTRY statement can cause total or partial storage association of storage sequences.

**See Also**
- Storage Association
- Assumed-Length Character Arguments
- COMMON
- ENTRY
- EQUIVALENCE

*Building Applications* for details on the hardware representations of data types

**Array Association**

A nonpointer array occupies a sequence of contiguous storage sequences, one for each array element, in array element order.

Two or more arrays are associated when each one is associated with the same storage location. They are partially associated when part of the storage associated with one array is the same as part or all of the storage associated with another array.

If arrays with different data types are associated (or partially associated) with the same storage location, and the value of one array is defined (for example, by assignment), the value of the other array becomes undefined. This happens because an element of an array is considered defined only if the storage associated with it contains data of the same type as the array name.

An array element, array section, or whole array is defined by a DATA statement before program execution. (The array properties must be declared in a previous specification statement.) During program execution, array elements and sections are defined by an assignment or input statement, and entire arrays are defined by input statements.

- Storage Association
- Arrays
- DATA statement
- Array Elements
Fortran 90 identified some FORTRAN 77 features to be obsolescent. Fortran 95 deletes some of these features, and identifies a few more language features to be obsolescent. Features considered obsolescent may be removed from future revisions of the Fortran Standard.

To have these features flagged, you can specify compiler option stand.

**NOTE.** Intel® Fortran fully supports features deleted from Fortran 95.

### Deleted Language Features in Fortran 95

Some language features, considered redundant in FORTRAN 77, are not included in Fortran 95. However, they are still fully supported by Intel® Fortran:

- ASSIGN and assigned GO TO statements
- Assigned FORMAT specifier
- Branching to an END IF statement from outside its IF block
- H edit descriptor
- PAUSE statement
- Real and double precision DO control variables and DO loop control expressions

Intel Fortran flags these features if you specify compiler option stand.

### See Also

- Deleted and Obsolescent Language Features
- Obsolescent Language Features in Fortran 90

### Obsolescent Language Features in Fortran 95

Some language features, considered redundant in Fortran 90 are identified as obsolescent in Fortran 95.

Intel® Fortran flags these features if you specify compiler option stand.

Other methods are suggested to achieve the functionality of the following obsolescent features:
• Alternate returns
  To replace this functionality, it is recommended that you use an integer variable to return a value to the calling program, and let the calling program use a **CASE construct** to test the value and perform operations.

• Arithmetic IF
  To replace this functionality, it is recommended that you use an **IF statement or construct**.

• Assumed-length character functions
  To replace this functionality, it is recommended that you use one of the following:
  • An automatic character-length function, where the length of the function result is declared in a specification expression
  • A subroutine whose arguments correspond to the function result and the function arguments

  Dummy arguments of a function can still have assumed character length; this feature is not obsolescent.

• CHARACTER*(*) form of CHARACTER declaration
  To replace this functionality, it is recommended that you use the Fortran 90 forms of specifying a length selector in CHARACTER declarations (see Declaration Statements for Character Types).

• Computed GO TO statement
  To replace this functionality, it is recommended that you use a **CASE construct**.

• DATA statements among executable statements
  This functionality has been included since FORTRAN 66, but is considered to be a potential source of errors.

• Fixed source form
  Newer methods of entering data have made this source form obsolescent and error-prone. The recommended method for coding is to use **free source form**.

• Shared DO termination and termination on a statement other than END DO or CONTINUE
  To replace this functionality, it is recommended that you use an END DO statement (see Forms for DO Constructs) or a **CONTINUE statement**.

• Statement functions
  To replace this functionality, it is recommended that you use an **internal function**.
Obsolescent Language Features in Fortran 90

Fortran 90 did not delete any of the features in FORTRAN 77, but some FORTRAN 77 features were identified as obsolescent.

Intel® Fortran flags these features if you specify compiler option stand.

Other methods are suggested to achieve the functionality of the following obsolescent features:

- **Alternate return (labels in an argument list)**
  To replace this functionality, it is recommended that you use an integer variable to return a value to the calling program, and let the calling program test the value and perform operations, using a computed GO TO statement or CASE construct.

- **Arithmetic IF**
  To replace this functionality, it is recommended that you use an IF statement or construct.

- **ASSIGN and assigned GO TO statements**
  These statements are usually used to simulate internal procedures, which can now be coded directly.

- **Assigned FORMAT specifier (label of a FORMAT statement assigned to an integer variable)**
  To replace this functionality, it is recommended that you use character expressions to define format specifications.

- **Branching to an END IF statement from outside its IF block**
  To replace this functionality, it is recommended that you branch to the statement following the END IF statement (see IF Construct).

- **H edit descriptor**
  To replace this functionality, it is recommended that you use the character constant edit descriptor (see Character Constant Editing).

- **PAUSE statement**
  To replace this functionality, it is recommended that you use a READ statement that awaits input data.

- **Real and double precision DO control variables and DO loop control expressions**
  To replace this functionality, it is recommended that you use integer DO variables and expressions (see DO Constructs).

- **Shared DO termination and termination on a statement other than END DO or CONTINUE**
  To replace this functionality, it is recommended that you use an END DO statement (see Forms for DO Constructs) or a CONTINUE statement.
To facilitate compatibility with older versions of Fortran, Intel® Fortran provides the following additional language features:

- The DEFINE FILE statement
- The ENCODE and DECODE statements
- The FIND statement
- The INTERFACE TO statement
- FORTRAN 66 Interpretation of the EXTERNAL Statement
- An alternative syntax for the PARAMETER statement
- The VIRTUAL statement
- An alternative syntax for octal and hexadecimal constants
- An alternative syntax for a record specifier
- An alternate syntax for the DELETE statement
- An alternative form for namelist external records
- The integer POINTER statement
- Record structures

These language features are particularly useful in porting older Fortran programs to Fortran 95/90. However, you should avoid using them in new programs on these systems, and in new programs for which portability to other Fortran 95/90 implementations is important.

**FORTRAN 66 Interpretation of the EXTERNAL Statement**

If you specify compiler option f66, the EXTERNAL statement is interpreted in a way that facilitates compatibility with older versions of Fortran. (The Fortran 95/90 interpretation is incompatible with previous Fortran standards and previous Compaq* implementations.)

The FORTRAN 66 interpretation of the EXTERNAL statement combines the functionality of the INTRINSIC statement with that of the EXTERNAL statement.

This lets you use subprograms as arguments to other subprograms. The subprograms to be used as arguments can be either user-supplied functions or Fortran 95/90 library functions.

The FORTRAN 66 EXTERNAL statement takes the following form:

EXTERNAL [ ^ ] v [, [ ^ ] v ] ...
Specifies that a user-supplied function is to be used instead of a Fortran 95/90 library function having the same name.

\( \triangleright \) Is the name of a subprogram or the name of a dummy argument associated with the name of a subprogram.

**Description**

The FORTRAN 66 EXTERNAL statement declares that each name in its list is an external function name. Such a name can then be used as an actual argument to a subprogram, which then can use the corresponding dummy argument in a function reference or CALL statement.

However, when used as an argument, a complete function reference represents a value, not a subprogram name; for example, SQRT(B) in CALL SUBR(A, SQRT(B), C). It is not, therefore, defined in an EXTERNAL statement (as would be the incomplete reference SQRT).
Examples

The following example shows the FORTRAN 66 EXTERNAL statement:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subprograms</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERNAL SIN, COS, *TAN, SINDEG</td>
<td>SUBROUTINE TRIG(X,F,Y)</td>
</tr>
<tr>
<td></td>
<td>Y = F(X)</td>
</tr>
<tr>
<td></td>
<td>RETURN</td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE, SIN, SINE)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>CALL TRIG(ANGLE, COS, COSINE)</td>
<td>RETURN</td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>CALL TRIG(ANGLE, TAN, TANGNT)</td>
<td>FUNCTION SINDEG(X)</td>
</tr>
<tr>
<td></td>
<td>SINDEG = SIN(X*3.1459/180)</td>
</tr>
<tr>
<td></td>
<td>RETURN</td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
<tr>
<td>CALL TRIG(ANGLED, SINDEG, SINE)</td>
<td></td>
</tr>
</tbody>
</table>

The CALL statements pass the name of a function to the subroutine TRIG. The function reference F(X) subsequently invokes the function in the second statement of TRIG. Depending on which CALL statement invoked TRIG, the second statement is equivalent to one of the following:

Y = SIN(X)
Y = COS(X)
Y = TAN(X)
Y = SINDEG(X)
The functions SIN and COS are examples of trigonometric functions supplied in the Fortran 95/90 library. The function TAN is also supplied in the library, but the asterisk (*) in the EXTERNAL statement specifies that the user-supplied function be used, instead of the library function. The function SINDEG is also a user-supplied function. Because no library function has the same name, no asterisk is required.

**See Also**
- Additional Language Features
- f66 compiler option

**Alternative Syntax for the PARAMETER Statement**

The PARAMETER statement discussed here is similar to the one discussed in PARAMETER; they both assign a name to a constant. However, this PARAMETER statement differs from the other one in the following ways:

- Its list is not bounded with parentheses.
- The form of the constant, rather than implicit or explicit typing of the name, determines the data type of the variable.

This PARAMETER statement takes the following form:

```
PARAMETER c = expr [, c = expr] ...
```

- `c` is the name of the constant.
- `expr` is an initialization expression. It can be of any data type.

**Description**

Each name `c` becomes a constant and is defined as the value of expression `expr`. Once a name is defined as a constant, it can appear in any position in which a constant is allowed. The effect is the same as if the constant were written there instead of the name.

The name of a constant cannot appear as part of another constant, except as the real or imaginary part of a complex constant. For example:

```
PARAMETER I=3
PARAMETER M=1.25 ! Not allowed
PARAMETER N=(1.703, I) ! Allowed
```
The name used in the PARAMETER statement identifies only the name’s corresponding constant in that program unit. Such a name can be defined only once in PARAMETER statements within the same program unit.

The name of a constant assumes the data type of its corresponding constant expression. The data type of a parameter constant cannot be specified in a type declaration statement. Nor does the initial letter of the constant’s name implicitly affect its data type.

**Examples**

The following are valid examples of this form of the PARAMETER statement:

```
PARAMETER PI=3.1415927, DPI=3.141592653589793238D0
PARAMETER PIOV2=PI/2, DPIOV2=DPI/2
PARAMETER FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS'
```

**Alternative Syntax for Binary, Octal, and Hexadecimal Constants**

In Intel Fortran, you can use an alternative syntax for binary, octal, and hexadecimal constants. The following table shows the alternative syntax and equivalents:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Alternative Syntax</th>
<th>Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary</td>
<td>'0..1'B</td>
<td>B'0..1'</td>
</tr>
<tr>
<td>Octal</td>
<td>'0..7'O</td>
<td>O'0..7'</td>
</tr>
<tr>
<td>Hexadecimal</td>
<td>'0..F'X</td>
<td>X'0..F'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Z'0..F'</td>
</tr>
</tbody>
</table>

You can use a quotation mark (") in place of an apostrophe in all the above syntax forms. For information on the # syntax for integers not in base 10, see Integer Constants.

**See Also**

- Additional Language Features
- Binary constants
- Octal constants
Alternative Syntax for a RecordSpecifier

In Intel® Fortran, you can specify the following form for a record specifier in an I/O control list:

'r

r Is a numeric expression with a value that represents the position of the record to be accessed using direct access I/O.

The value must be greater than or equal to 1, and less than or equal to the maximum number of records allowed in the file. If necessary, a record number is converted to integer data type before being used.

If this nonkeyword form is used in an I/O control list, it must immediately follow the nonkeyword form of the io-unit specifier.

Alternative Syntax for the DELETE Statement

In Intel® Fortran, you can specify the following form of the DELETE statement when deleting records from a relative file:

DELETE (io-unit 'r [, ERR=label] [, IOSTAT=i-var])

io-unit Is the number of the logical unit containing the record to be deleted.

r Is the positional number of the record to be deleted.

label Is the label of an executable statement that receives control if an error condition occurs.

i-var Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

This form deletes the direct access record specified by r.

See Also

- Additional Language Features
- DELETE statement

Alternative Form for Namelist External Records

In Intel® Fortran, you can use the following form for an external record:

$group-name object = value [object = value] ...$[END]
group-name is the name of the group containing the objects to be given values. The name must have been previously defined in a NAMELIST statement in the scoping unit.

object is the name (or subobject designator) of an entity defined in the NAMELIST declaration of the group name. The object name must not contain embedded blanks, but it can be preceded or followed by blanks.

value is a null value, a constant (or list of constants), a repetition of constants in the form r*c, or a repetition of null values in the form r*.

If more than one object=value or more than one value is specified, they must be separated by value separators.

A value separator is any number of blanks, or a comma or slash, preceded or followed by any number of blanks.

- NAMELIST statement
- Rules for Namelist Sequential READ Statements
- Rules for Namelist Sequential WRITE Statements

Record Structures

The record structure was defined in earlier versions of Intel® Fortran as a language extension. It is still supported, although its functionality has been replaced by standard Fortran 95/90 derived data types. Record structures in existing code can be easily converted to Fortran 95/90 derived type structures for portability, but can also be left in their old form. In most cases, an Intel Fortran record and a Fortran 95/90 derived type can be used interchangeably.

Intel Fortran record structures are similar to Fortran 95/90 derived types.

A record structure is an aggregate entity containing one or more elements. (Record elements are also called fields or components.) You can use records when you need to declare and operate on multi-field data structures in your programs.

Creating a record is a two-step process:

1. You must define the form of the record with a multistatement structure declaration.
2. You must use a RECORD statement to declare the record as an entity with a name. (More than one RECORD statement can refer to a given structure.)
Examples
Intel Fortran record structures, using only intrinsic types, easily convert to Fortran 95/90 derived types. The conversion can be as simple as replacing the keyword STRUCTURE with TYPE and removing slash (/) marks. The following shows an example conversion:

<table>
<thead>
<tr>
<th>Record Structure</th>
<th>Fortran 95/90 Derived-Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRUCTURE /employee_name/</td>
<td>TYPE employee_name</td>
</tr>
<tr>
<td>CHARACTER*25  last_name</td>
<td>CHARACTER*25  last_name</td>
</tr>
<tr>
<td>CHARACTER*15  first_name</td>
<td>CHARACTER*15  first_name</td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td>END TYPE</td>
</tr>
<tr>
<td>STRUCTURE /employee_addr/</td>
<td>TYPE employee_addr</td>
</tr>
<tr>
<td>CHARACTER*20  street_name</td>
<td>CHARACTER*20  street_name</td>
</tr>
<tr>
<td>INTEGER(2)  street_number</td>
<td>INTEGER(2)  street_number</td>
</tr>
<tr>
<td>INTEGER(2)  apt_number</td>
<td>INTEGER(2)  apt_number</td>
</tr>
<tr>
<td>CHARACTER*20  city</td>
<td>CHARACTER*20  city</td>
</tr>
<tr>
<td>CHARACTER*2  state</td>
<td>CHARACTER*2  state</td>
</tr>
<tr>
<td>INTEGER(4)  zip</td>
<td>INTEGER(4)  zip</td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td>END TYPE</td>
</tr>
</tbody>
</table>

The record structures can be used as subordinate record variables within another record, such as the employee_data record. The equivalent Fortran 90 derived type would use the derived-type objects as components in a similar manner, as shown below:

<table>
<thead>
<tr>
<th>Record Structure</th>
<th>Fortran 95/90 Derived-Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRUCTURE /employee_data/</td>
<td>TYPE employee_data</td>
</tr>
<tr>
<td>RECORD /employee_name/ name</td>
<td>TYPE (employee_name) name</td>
</tr>
<tr>
<td>RECORD /employee_addr/ addr</td>
<td>TYPE (employee_addr) addr</td>
</tr>
<tr>
<td>INTEGER(4)  telephone</td>
<td>INTEGER(4)  telephone</td>
</tr>
<tr>
<td>INTEGER(2)  date_of_birth</td>
<td>INTEGER(2)  date_of_birth</td>
</tr>
<tr>
<td>INTEGER(2)  date_of_hire</td>
<td>INTEGER(2)  date_of_hire</td>
</tr>
<tr>
<td>INTEGER(2)  social_security(3)</td>
<td>INTEGER(2)  social_security(3)</td>
</tr>
<tr>
<td>Record Structure</td>
<td>Fortran 95/90 Derived-Type</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>LOGICAL(2) married</td>
<td>LOGICAL(2) married</td>
</tr>
<tr>
<td>INTEGER(2) dependents</td>
<td>INTEGER(2) dependents</td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td>END TYPE</td>
</tr>
</tbody>
</table>

## Structure Declarations

A **structure declaration** defines the field names, types of data within fields, and order and alignment of fields within a record. Fields and structures can be initialized, but records cannot be initialized. For more information, see **STRUCTURE**.

### Type Declarations within Record Structures

The syntax of a type declaration within a record structure is identical to that of a normal Fortran type statement.

The following rules and behavior apply to type declarations in record structures:

- `%FILL` can be specified in place of a field name to leave space in a record for purposes such as alignment. This creates an unnamed field.
  
  `%FILL` can have an array specification; for example:
  
  ```fortran
  INTEGER %FILL (2,2)
  ```

  Unnamed fields cannot be initialized. For example, the following statement is invalid and generates an error message:
  
  ```fortran
  INTEGER %FILL /1980/
  ```

- Initial values can be supplied in field declaration statements. Unnamed fields cannot be initialized; they are always undefined.
• Field names must always be given explicit data types. The IMPLICIT statement does not affect field declarations.
• Any required array dimensions must be specified in the field declaration statements. DIMENSION statements cannot be used to define field names.
• Adjustable or assumed sized arrays and assumed-length CHARACTER declarations are not allowed in field declarations.

Substructure Declarations
A field within a structure can itself be a structured item composed of other fields, other structures, or both. You can declare a substructure in two ways:

• By nesting structure declarations within other structure or union declarations (with the limitation that you cannot refer to a structure inside itself at any level of nesting).
  One or more field names must be defined in the STRUCTURE statement for the substructure, because all fields in a structure must be named. In this case, the substructure is being used as a field within a structure or union.
  Field names within the same declaration nesting level must be unique, but an inner structure declaration can include field names used in an outer structure declaration without conflict.
• By using a RECORD statement that specifies another previously defined record structure, thereby including it in the structure being declared.

See the example in STRUCTURE for a sample structure declaration containing both a nested structure declaration (TIME) and an included structure (DATE).

References to Record Fields
References to record fields must correspond to the kind of field being referenced. Aggregate field references refer to composite structures (and substructures). Scalar field references refer to singular data items, such as variables.
An operation on a record can involve one or more fields.
Record field references take one of the following forms:

Aggregate Field Reference:

\[ \text{record-name} \[.\text{aggregate-field-name}\] ... \]

Scalar Field Reference:

\[ \text{record-name} \[.\text{aggregate-field-name}\] ... .\text{scalar-field-name} \]

**record-name** Is the name used in a RECORD statement to identify a record.

**aggregate-field-name** Is the name of a field that is a substructure (a record or a nested structure declaration) within the record structure identified by the record name.

**scalar-field-name** Is the name of a data item (having a data type) defined within a structure declaration.

**Description**

Records and record fields cannot be used in DATA statements, but individual fields can be initialized in the STRUCTURE definition.

An automatic array cannot be a record field.

A scalar field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names followed by the name of a scalar field. A scalar field reference refers to a single data item (having a data type) and can be treated like a normal reference to a Fortran variable or array element.

You can use scalar field references in statement functions and in executable statements. However, they cannot be used in COMMON, SAVE, NAMELIST, or EQUIVALENCE statements, or as the control variable in an indexed DO-loop.

Type conversion rules for scalar field references are the same as those for variables and array elements.

An aggregate field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names.

You can only assign an aggregate field to another aggregate field (record = record) if the records have the same structure. Intel® Fortran supports no other operations (such as arithmetic or comparison) on aggregate fields.

Intel Fortran requires qualification on all levels. While some languages allow omission of aggregate field names when there is no ambiguity as to which field is intended, Intel Fortran requires all aggregate field names to be included in references.

You can use aggregate field references in unformatted I/O statements; one I/O record is written no matter how many aggregate and array name references appear in the I/O list. You cannot use aggregate field references in formatted, namelist, and list-directed I/O statements.
You can use aggregate field references as actual arguments and record dummy arguments. The declaration of the dummy record in the subprogram must match the form of the aggregate field reference passed by the calling program unit; each structure must have the same number and types of fields in the same order. The order of map fields within a union declaration is irrelevant.

Records are passed by reference. Aggregate field references are treated like normal variables. You can use adjustable arrays in RECORD statements that are used as dummy arguments.

**Examples**

The following examples show record and field references. Consider the following structure declarations:

**Structure DATE:**

```
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
END STRUCTURE
```

**Structure APPOINTMENT:**

```
STRUCTURE /APPOINTMENT/
  RECORD /DATE/   APP_DATE
  STRUCTURE /TIME/ APP_TIME(2)
    INTEGER*1 HOUR, MINUTE
END STRUCTURE
  CHARACTER*20 APP_MEMO(4)
  LOGICAL*1 APP_FLAG
END STRUCTURE
```

The following RECORD statement creates a variable named NEXT_APP and a 10-element array named APP_LIST. Both the variable and each element of the array take the form of the structure APPOINTMENT:

```
RECORD /APPOINTMENT/   NEXT_APP,APP_LIST(10)
```

Each of the following examples of record and field references are derived from the previous structure declarations and RECORD statement:
Aggregate Field References

- The record NEXT_APP:
  NEXT_APP

- The field APP_DATE, a 4-byte array field in the record array APP_LIST(3):
  APP_LIST(3).APP_DATE

Scalar Field References

- The field APP_FLAG, a LOGICAL field of the record NEXT_APP:
  NEXT_APP.APP_FLAG

- The first character of APP_MEMO(1), a CHARACTER*20 field of the record NEXT_APP:
  NEXT_APP.APP_MEMO(1)(1:1)

NOTE. Because periods are used in record references to separate fields, you should avoid using relational operators (.EQ., .XOR.), logical constants (.TRUE., .FALSE.), and logical expressions (.AND., .NOT., .OR.) as field names in structure declarations. Dots can also be used instead of % to separate fields of a derived type.
Consider the following example:

```fortran
module mod
  type T1_t
    integer :: i
  end type T1_t
  type T2_t
    type (T1_t) :: eq
    integer :: i
  end type T2_t
  interface operator (.eq.)
    module procedure eq_func
  end interface operator (.eq.)
contains
  function eq_func(t2, i) result (rslt)
    type(T2_t), intent (in) :: t2
    integer, intent (in) :: i
    rslt = t2%eq%i + i
  end function eq_func
end module mod
use mod
  type(T2_t) :: t2
  integer :: i
  t2%eq%i = 0
  t2%i = -10
  i = -10
  print *, t2.eq.i, (t2).eq.i
end
```

In this case, the reference "t2.eq.i" prints 0. The reference "(t2).eq.i" will invoke eq_func and will print -10.

Building Applications for details on alignment of data

Aggregate Assignment

For aggregate assignment statements, the variable and expression must have the same structure as the aggregate they reference.

The aggregate assignment statement assigns the value of each field of the aggregate on the right of an equal sign to the corresponding field of the aggregate on the left. Both aggregates must be declared with the same structure.
Examples

The following example shows valid aggregate assignments:

```fortran
STRUCTURE /DATE/
    INTEGER*1 DAY, MONTH
    INTEGER*2 YEAR
END STRUCTURE
RECORD /DATE/ TODAY, THIS_WEEK(7)
STRUCTURE / APPOINTMENT/
    ...
    RECORD /DATE/ APP_DATE
END STRUCTURE
RECORD /APPOINTMENT/ MEETING
DO I = 1,7
    CALL GET_DATE (TODAY)
    THIS_WEEK(I) = TODAY
    THIS_WEEK(I).DAY = TODAY.DAY + 1
END DO
MEETING.APP_DATE = TODAY
```
This topic contains information about the following additional character sets:

- Character and Key Code Charts for Windows* OS
- The ASCII Character Set for Linux* OS and Mac OS* X

**Character and Key Code Charts for Windows* OS**

This topic contains the ASCII and ANSI character code charts, and the Key code charts that are available on Windows* OS.

**ASCII Character Codes for Windows* Systems**

The ASCII character code charts contain the decimal and hexadecimal values of the extended ASCII (American Standards Committee for Information Interchange) character set. The extended character set includes the ASCII character set (Chart 1) and 128 other characters for graphics and line drawing (Chart 2), often called the "IBM* character set".
ASCII Character Codes Chart 1 (W*32, W*64)

2212
ASCII Character Codes Chart 2: IBM* Character Set (W*32, W*64)
ANSI Character Codes for Windows® Systems

The ANSI character code chart lists the extended character set of most of the programs used by Windows® systems. The codes of the ANSI (American National Standards Institute) character set from 32 through 126 are displayable characters from the ASCII character set. The ANSI characters displayed as solid blocks are undefined characters and may appear differently on output devices.
ANSI Character Codes Chart (W*32, W*64)
Key Codes for Windows* Systems

Some keys, such as function keys, cursor keys, and ALT+KEY combinations, have no ASCII code. When a key is pressed, a microprocessor within the keyboard generates an "extended scan code" of two bytes.

The first (low-order) byte contains the ASCII code, if any. The second (high-order) byte has the scan code—a unique code generated by the keyboard when a key is either pressed or released. Because the extended scan code is more extensive than the standard ASCII code, programs can use it to identify keys which do not have an ASCII code.

For more details on key codes, see:

• Key Codes Chart 1
• Key Codes Chart 2
Key Codes Chart 1 (W*32, W*64)
Key Codes Chart 2 (W*32, W*64)
**ASCII Character Set for Linux* OS and Mac OS* X**

This topic describes the ASCII character set that is available on Linux* OS and Mac OS* X. The ASCII character set contains characters with decimal values 0 through 127. The first half of each of the numbered columns identifies the character as you would enter it on a terminal or as you would see it on a printer. Except for SP and HT, the characters with names are nonprintable. In the figure, the characters with names are defined as follows:

<table>
<thead>
<tr>
<th>Character</th>
<th>Name</th>
<th>Character</th>
<th>Name</th>
<th>Character</th>
<th>Name</th>
</tr>

</table>

2220
The remaining half of each column identifies the character by the binary value of the byte; the value is stated in three radixes—octal, decimal, and hexadecimal. For example, the uppercase letter A has, under ASCII conventions, a storage value of hexadecimal 41 (a bit configuration of 01000001), equivalent to 101 in octal notation and 65 in decimal notation.
Figure 35: ASCII Character Set (L*X, M*X)
Several of the numeric intrinsic functions are defined by a model set for integers (for each intrinsic kind used) and reals (for each real kind used). The bit functions are defined by a model set for bits (binary digits).

The following intrinsic functions provide information on the data representation models:

<table>

</tbody>
</table>

For more information on the range of values for each data type (and kind), see *Building Applications*. This appendix discusses the following topics:

- The model for Integer Data
- The model for Real Data
- The model for Bit Data

### Model for Integer Data

In general, the model set for integers is defined as follows:

\[
i = s \times \sum_{k=1}^{q} w_k \times r^{k-1}
\]

The following values apply to this model set:
- \( i \) is the integer value.
- \( s \) is the sign (either +1 or -1).
- \( q \) is the number of digits (a positive integer).
- \( r \) is the radix (an integer greater than 1).
- \( w_k \) is a nonnegative number less than \( r \).

The model for INTEGER(4) follows:

\[
i = s \times \sum_{k=1}^{31} w_k \times r^{-k}
\]

The following example shows the general integer model for \( i = -20 \) using a base \( (r) \) of 2:

\[
i = (-1) \times (0 \times 2^0 + 0 \times 2^1 + 1 \times 2^2 + 0 \times 2^3 + 1 \times 2^4)
\]
\[
i = (-1) \times (4 + 16)
\]
\[
i = -20
\]

**Model for Real Data**

The model set for reals, in general, is defined as one of the following:

\[
x = 0
\]

\[
x = s \times b^e \times \sum_{k=1}^{n} f_k \times b^{-k}
\]

The following values apply to this model set:

- \( x \) is the real value.
- \( s \) is the sign (either +1 or -1).
- \( b \) is the base (real radix; an integer greater than 1; \( b = 2 \) in Intel® Fortran).
• $p$ is the number of mantissa digits (an integer greater than 1). The number of digits differs depending on the real format, as follows:

<table>
<thead>
<tr>
<th>Format</th>
<th>Format Type</th>
<th>Digits</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL(4)</td>
<td>IEEE S_floating</td>
<td>24</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>IEEE T_floating</td>
<td>53</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>IEEE X_floating</td>
<td>113</td>
</tr>
</tbody>
</table>

• $e$ is an integer in the range $e_{\text{min}}$ to $e_{\text{max}}$ inclusive. This range differs depending on the real format, as follows:

<table>
<thead>
<tr>
<th>Format</th>
<th>Format Type</th>
<th>$e_{\text{min}}$</th>
<th>$e_{\text{max}}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL(4)</td>
<td>IEEE S_floating</td>
<td>-125</td>
<td>128</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>IEEE T_floating</td>
<td>-1021</td>
<td>1024</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>IEEE X_floating</td>
<td>-16381</td>
<td>16384</td>
</tr>
</tbody>
</table>

• $f_k$ is a nonnegative number less than $b$ ($f_1$ is also nonzero).

For $x = 0$, its exponent $e$ and digits $f_k$ are defined to be zero.

The model set for single-precision real (REAL(4)) is defined as one of the following:

$$x = 0$$

$$x = s \times 2^e \times \left[1 / 2 + \sum_{k=2}^{24} f_k \times 2^{-k}\right], -125 \leq e \leq 128$$

The following example shows the general real model for $x = 20.0$ using a base ($b$) of 2:

$$x = 1 \times 2^5 \times (1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3})$$

$$x = 1 \times 32 \times (.5 + .125)$$

$$x = 32 \times (.625)$$

$$x = 20.0$$
Model for Bit Data

The model set for bits (binary digits) interprets a nonnegative scalar data object of type integer as a sequence, as follows:

\[ j = \sum_{k=0}^{s-1} w_k \times 2^k \]

The following values apply to this model set:
- \( j \) is the integer value.
- \( s \) is the number of bits.
- \( w_k \) is a bit value of 0 or 1.

The bits are numbered from right to left beginning with 0.

The following example shows the bit model for \( j = 1001 \) (integer 9) using a bit number \( s \) of 4:

\[
\begin{array}{cccc}
1 & 0 & 0 & 1 \\
\downarrow & \downarrow & \downarrow & \downarrow \\
w_3 & w_2 & w_1 & w_0 \\
\end{array}
\]

\[
j = (w_0 \times 2^0) + (w_1 \times 2^1) + (w_2 \times 2^2) + (w_3 \times 2^3)
\]

\[
j = 0 + 0 + 0 + 8
\]

\[
j = 9
\]
Run-Time Library Routines

Intel® Fortran provides the following run-time library routines, which are summarized in this appendix:

- Module routines
- OpenMP® Fortran routines

Module Routines

Intel® Fortran provides library modules containing the following routines:

- Routines that help you write programs for graphics, QuickWin, and other applications (in modules IFQWIN, IFLOGM, and IFCORE):
  - QuickWin routines (W*32, W*64)
  - Graphics routines (W*32, W*64)
  - Dialog routines (W*32, W*64)
  - Miscellaneous run-time routines

- Routines systems that help you write programs using Component Object Model (COM) and Automation servers (in modules IFCOM and IFAUTO):
  - COM routines (W*32, W*64)
  - AUTO routines (W*32, W*64)

- Portability routines that help you port your programs to or from other systems, or help you perform basic I/O to serial ports on Windows* systems (in module IFPORT).

- National Language Support routines that help you write foreign language programs for international markets (in module IFNLS). These routines are only available on Windows* systems.

- POSIX routines that help you write Fortran programs that comply with the POSIX* Standard (in module IFPOSIX).

When you include the statement USE module-name in your program, these library routines are automatically linked to your program if called.

You can restrict what is accessed from a USE module by adding ONLY clauses to the USE statement.

- Run-Time Library Routines
OpenMP Fortran Routines

The following table summarizes the OpenMP Fortran API run-time library routines you can use for directed parallel decomposition. These routines are all external procedures.

To use these routines, you must add a USE OMP_LIB statement to the program unit containing the routine.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OMP_SET_NUM_THREADS</td>
<td>Sets the number of threads to use for the next parallel region.</td>
</tr>
<tr>
<td>OMP_GET_NUM_THREADS</td>
<td>Gets the number of threads currently in the team executing the parallel region from which the routine is called.</td>
</tr>
<tr>
<td>OMP_GET_MAX_THREADS</td>
<td>Gets the maximum value that can be returned by calls to the OMP_GET_NUM_THREADS function.</td>
</tr>
<tr>
<td>OMP_GET_THREAD_NUM</td>
<td>Gets the thread number, within the team, in the range from zero to OMP_GET_NUM_THREADS minus one.</td>
</tr>
<tr>
<td>OMP_GET_NUM_PROCS</td>
<td>Gets the number of processors that are available to the program.</td>
</tr>
<tr>
<td>OMP_IN_PARALLEL</td>
<td>Informs whether or not a region is executing in parallel.</td>
</tr>
<tr>
<td>OMP_SET_DYNAMIC</td>
<td>Enables or disables dynamic adjustment of the number of threads available for execution of parallel regions.</td>
</tr>
<tr>
<td>OMP_GET_DYNAMIC</td>
<td>Informs whether or not dynamic thread adjustment is enabled.</td>
</tr>
<tr>
<td>OMP_SET_NESTED</td>
<td>Enables or disables nested parallelism.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OMP_GET_NESTED</td>
<td>Informs whether or not nested parallelism is enabled.</td>
</tr>
<tr>
<td>OMP_INIT_LOCK</td>
<td>Initializes a lock to be used in subsequent calls.</td>
</tr>
<tr>
<td>OMP_DESTROY_LOCK</td>
<td>Disassociates a lock variable from any locks.</td>
</tr>
<tr>
<td>OMP_SET_LOCK</td>
<td>Makes the executing thread wait until the specified lock is available.</td>
</tr>
<tr>
<td>OMP_UNSET_LOCK</td>
<td>Releases the executing thread from ownership of a lock.</td>
</tr>
<tr>
<td>OMP_TEST_LOCK</td>
<td>Tries to set the lock associated with a lock variable.</td>
</tr>
<tr>
<td>OMP_INIT_NEST_LOCK</td>
<td>Initializes a nested lock for use in subsequent calls.</td>
</tr>
<tr>
<td>OMP_DESTROY_NEST_LOCK</td>
<td>Disassociates a lock variable from a nested lock.</td>
</tr>
<tr>
<td>OMP_SET_NEST_LOCK</td>
<td>Makes the executing thread wait until the specified nested lock is available.</td>
</tr>
<tr>
<td>OMP_UNSET_NEST_LOCK</td>
<td>Releases the executing thread from ownership of a nested lock if the nesting count is zero.</td>
</tr>
<tr>
<td>OMP_TEST_NEST_LOCK</td>
<td>Tries to set the nested lock associated with a lock variable.</td>
</tr>
<tr>
<td>OMP_GET_WTIME</td>
<td>Returns a double-precision value equal to the elapsed wallclock time (in seconds) relative to an arbitrary reference time.</td>
</tr>
<tr>
<td>OMP_GETWTICK</td>
<td>Returns a double-precision value equal to the number of seconds between successive clock ticks.</td>
</tr>
</tbody>
</table>

**Intel® Fortran Extensions:**
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KMP_GET_STACKSIZE_S&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Returns the number of bytes that will be allocated for each parallel thread to use as its private stack.</td>
</tr>
<tr>
<td>KMP_SET_STACKSIZE_S&lt;sup&gt;2&lt;/sup&gt;</td>
<td>Sets the number of bytes that will be allocated for each parallel thread to use as its private stack.</td>
</tr>
<tr>
<td>KMP_GET_BLOCKTIME</td>
<td>Returns the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping.</td>
</tr>
<tr>
<td>KMP_SET_BLOCKTIME</td>
<td>Sets the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping.</td>
</tr>
<tr>
<td>KMP_MALLOC</td>
<td>Allocates a memory block of a specified size (in bytes) from the thread-local heap.</td>
</tr>
<tr>
<td>KMP_CALLOC</td>
<td>Allocates an array of a specified number of elements and size from the thread-local heap.</td>
</tr>
<tr>
<td>KMP_REALLOC</td>
<td>Reallocates a memory block at a specified address and of a specified size from the thread-local heap.</td>
</tr>
<tr>
<td>KMP_FREE</td>
<td>Frees a memory block at a specified address from the thread-local heap.</td>
</tr>
</tbody>
</table>

<sup>1</sup> For backwards compatibility, this can also be specified as KMP_GET_STACKSIZE.

<sup>2</sup> For backwards compatibility, this can also be specified as KMP_SET_STACKSIZE.

For more information on a specific routine, see the appropriate reference page; for example, for more information on OMP_SET_LOCK, see `omp_set_lock(3f)`.

Summary of Language Extensions

This appendix summarizes the Intel® Fortran language extensions to the ANSI/ISO Fortran 95 Standard. Most extensions are available on all supported operating systems. However, some extensions are limited to one or more platforms. If an extension is limited, it is labeled.

Extensions related to the following topics are discussed:

- Source Forms
- Names
- Character Sets
- Intrinsic Data Types
- Constants
- Expressions and Assignment
- Specification Statements
- Execution Control
- Program Units and Procedures
- Compilation Control Statements
- Built-In Functions
- I/O Statements
- I/O Formatting
- File Operation Statements
- Compiler Directives
- Intrinsic Procedures
- Additional Language Features
- Run-Time Library Routines

Language Extensions: Source Forms

The following are extensions to the methods and rules for source forms:

- Tab-formatting as a method to code lines
- The letter D as a debugging statement indicator in column 1 of fixed or tab source form
• An optional statement field width of 132 columns for fixed or tab source form
• An optional sequence number field for fixed source form
• Up to 511 continuation lines in a source program

Language Extensions: Names
The following are extensions to the Fortran 90 rules for names (see names):
• Names can contain up to 63 characters
• The dollar sign ($) is a valid character in names, and can be the first character

Language Extensions: Character Sets
The following are extensions to the Fortran 90 character set:
• The Tab (<Tab>) character (see Character Sets)
• ASCII Character Code Chart 2 -- IBM* Character Set
• ANSI Character Code Chart
• Key Code Charts

Language Extensions: Intrinsic Data Types
The following are data-type extensions:

<table>
<thead>
<tr>
<th>BYTE</th>
<th>INTEGER*1</th>
<th>REAL*16</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOUBLE COMPLEX</td>
<td>INTEGER*2</td>
<td>COMPLEX*8</td>
</tr>
<tr>
<td>LOGICAL*1</td>
<td>INTEGER*4</td>
<td>COMPLEX*16</td>
</tr>
<tr>
<td>LOGICAL*2</td>
<td>INTEGER*8</td>
<td>COMPLEX*32</td>
</tr>
<tr>
<td>LOGICAL*4</td>
<td>REAL*4</td>
<td></td>
</tr>
<tr>
<td>LOGICAL*8</td>
<td>REAL*8</td>
<td></td>
</tr>
</tbody>
</table>
See Also

- Summary of Language Extensions
- Intrinsic Data Types

Language Extensions: Constants

Hollerith constants are allowed as an extension.

C Strings are allowed as extensions in character constants.

Language Extensions: Expressions and Assignment

When operands of different intrinsic data types are combined in expressions, conversions are performed as necessary (see Data Type of Numeric Expressions).

Binary, octal, hexadecimal, and Hollerith constants can appear wherever numeric constants are allowed.

The following are extensions allowed in logical expressions:

- .XOR. as a synonym for .NEQV.
- Integers as valid logical items
- Logical operators applied to integers bit-by-bit

Language Extensions: Specification Statements

The following specification attributes and statements are extensions:

- AUTOMATIC attribute and statement
- PROTECTED attribute and statement
- STATIC attribute and statement
- VOLATILE attribute and statement

A double colon is now optional for the INTRINSIC, SAVE, STATIC, AUTOMATIC, EXTERNAL, and VOLATILE statements.

Language Extensions: Execution Control

The following control statements are extensions to Fortran 95:
ASSIGN
Assigned GO TO
PAUSE

These are older Fortran features that have been deleted in Fortran 95. Intel® Fortran fully supports these features.

Language Extensions: Program Units and Procedures

The following program units and statement are extensions:

- Intrinsic modules
- The IMPORT statement

Language Extensions: Compilation Control Lines and Statements

The following line option and statement are extensions that can influence compilation:

- [/][NO]LIST], which can be specified in an INCLUDE line
- The OPTIONS statement

Language Extensions: Built-In Functions

The following built-in functions are extensions:

- %VAL, %REF, and %LOC, which facilitate references to non-Fortran procedures
- %FILL, which can be used in record structure type definitions

Language Extensions: I/O Statements

The following I/O statements are extensions:

- The ACCEPT statement
- The FLUSH statement
- The REWRITE statement
- The TYPE statement, which is a synonym for the PRINT statement
- The WAIT statement
**Language Extensions: I/O Formatting**

The following are extensions allowed in I/O Formatting:

- The Q edit descriptor
- The dollar sign ($) edit descriptor and carriage-control character
- The backslash (\) edit descriptor
- The ASCII NUL carriage-control character
- Variable format expressions
- The H edit descriptor

This is an older Fortran feature that has been deleted in Fortran 95. Intel® Fortran fully supports this feature.

**Language Extensions: File Operation Statements**

The following statement specifiers and statements are extensions:

- **CLOSE** statement specifiers:
  - STATUS values: 'SAVE' (as a synonym for 'KEEP'), 'PRINT', 'PRINT/DELETE', 'SUBMIT', 'SUBMIT/DELETE'
  - DISPOSE (or DISP)
- **DELETE** statement
- **INQUIRE** statement specifiers:
  - ASYNCHRONOUS
  - BINARY (W*32, W*64)
  - BLOCKSIZE
  - BUFFERED
  - CARRIAGECONTROL
  - CONVERT
  - DEFAULTFILE
  - FORM values: 'UNKNOWN', 'BINARY' (W*32, W*64)
  - IOFOCUS (W*32, W*64)
• MODE as a synonym for ACTION
• ORGANIZATION
• PENDING
• POS
• RECORDTYPE
• SHARE (W*32, W*64)

See also INQUIRE Statement.

• OPEN statement specifiers:
  • ACCESS values: 'APPEND'
  • ASSOCIATEVARIABLE
  • ASYNCHRONOUS
  • BLOCKSIZE
  • BUFFERCOUNT
  • BUFFERED
  • CARRIAGECONTROL
  • CONVERT
  • DEFAULTFILE
  • DISPOSE (or DISP)
  • FORM value: 'BINARY' (W*32, W*64)
  • IOFOCUS (W*32, W*64)
  • MAXREC
  • MODE as a synonym for ACTION
  • NAME as a synonym for FILE
  • NOSHARED
  • ORGANIZATION
  • READONLY
  • RECORDSIZE as a synonym for RECL
  • RECORDTYPE
  • SHARE (W*32, W*64)
  • SHARED
  • TITLE (W*32, W*64)
• TYPE as a synonym for STATUS
• USEROPEN

See also OPEN Statement.

Language Extensions: Compiler Directives

The following General Directives are extensions:

• ALIAS
• ASSUME_ALIGNED
• ATTRIBUTES
• DECLARE and NODECLARE
• DEFINE and UNDEFINE
• DISTRIBUTE POINT
• FIXEDFORMLINESIZE
• FREEFORM and NOFREEFORM
• IDENT
• IF and IF DEFINED
• INTEGER
• IVDEP
• LOOP COUNT
• MEMORYTOUCH (i64 only)
• MEMREF_CONTROL (i64 only)
• MESSAGE
• OBJCOMMENT
• OPTIMIZE and NOOPTIMIZE
• OPTIONS
• PACK
• PARALLEL and NOPARALLEL (loop)
• PREFETCH and NOPREFETCH
• PSECT
• REAL
• STRICT and NOSTRICT
• SWP and NOSWP (i64 only)
• UNROLL and NOUNROLL
• UNROLL_AND_JAM and NOUNROLL_AND_JAM
• VECTOR ALIGNED and VECTOR UNALIGNED
• VECTOR ALWAYS and NOVECTOR
• VECTOR TEMPORAL and VECTOR NONTEMPORAL (i32, i64em)

The following OpenMP* Fortran directives are extensions:

• ATOMIC
• BARRIER
• CRITICAL
• DO
• FLUSH
• MASTER
• ORDERED
• PARALLEL
• PARALLEL DO
• PARALLEL SECTIONS
• PARALLEL WORKSHARE
• SECTIONS
• SINGLE
• TASK
• TASKWAIT
• THREADPRIVATE
• WORKSHARE

**Language Extensions: Intrinsic Procedures**

The following intrinsic procedures are extensions available on all platforms:

Language Extensions: Additional Language Features

The following are language extensions that facilitate compatibility with other versions of Fortran:

- DEFINE FILE statement
- ENCODE and DECODE statements
- FIND statement
- The INTERFACE TO statement
• FORTRAN 66 Interpretation of the EXTERNAL statement
• An alternative syntax for the PARAMETER statement
• VIRTUAL statement
• AND, OR, XOR, IMAG, LSHIFT, RSHIFT intrinsics (see the A to Z Reference)
• An alternative syntax for octal and hexadecimal constants
• An alternative syntax for an I/O record specifier
• An alternate syntax for the DELETE statement
• An alternative form for namelist external records
• The integer POINTER statement
• Record structures

Language Extensions: Run-Time Library Routines

The following run-time library routines are available as extensions:
• Module routines
• OpenMP* Fortran routines
This section contains the following:

- **Language Summary Tables**
  This section organizes the functions, subroutines, and statements available in Intel® Fortran by the operations they perform. You can use the tables to locate a particular routine for a particular task.
  The descriptions of all Intel Fortran statements, intrinsics, directives, and module library routines, which are listed in alphabetical order.
  In the description of routines, pointers and handles are INTEGER(4) on IA-32 architecture and INTEGER(8) on Intel® 64 architecture and IA-64 architecture.

The Fortran compiler understands statements and intrinsic functions in your program without any additional information, such as that provided in modules.

However, modules must be included in programs that contain the following routines:

- **Quickwin routines and graphics routines (W*32, W*64)**
  These routines require a USE IFQWIN statement to include the library and graphics modules.

- **Portability routines and serial port I/O routines**
  These routines require a USE IFPORT statement to access the portability library. The serial port I/O routines are only available on Windows* systems.

- **NLS routines (W*32, W*64)**
  These routines require a USE IFNLS statement to access the NLS library.

- **POSIX* routines**
  These routines require a USE IFPOSIX statement to access the POSIX library.

- **Dialog routines (W*32, W*64)**
  These routines require a USE IFLOGM statement to access the dialog library.

- **Component Object Module (COM) routines (W*32, W*64)**
  These routines require a USE IFCOM statement to access the COM library.

- **Automation server routines (W*32, W*64)**
  These routines require a USE IFAUTO statement to access the AUTO library.

- **Miscellaneous Run-Time Routines**
  Most of these routines require a USE IFCORE statement to obtain the proper interfaces.
Whenever required, these USE module statements are prominent in the A to Z Reference. In addition to the appropriate USE statement, for some routines you must specify the types of libraries to be used when linking.

**Language Summary Tables**

The Fortran procedures and statements have been organized into the following tables:

- Statements for Program Unit Calls and Definition
- Statements Affecting Variables
- Statements for Input and Output
- Compiler Directives
- Program Control Statements and Procedures
- Inquiry Intrinsic Procedures
- Random Number Intrinsic Procedures
- Date and Time Intrinsic Subroutines
- Keyboard and Speaker Library Routines
- Statements and Intrinsic Procedures Memory Allocation and Deallocation
- Intrinsic Functions for Arrays
- Intrinsic Functions for Numeric and Type Conversion
- Trigonometric, Exponential, Root, and Logarithmic Intrinsic Procedures
- Intrinsic Functions for Floating-Point Inquiry and Control
- Character Intrinsic Functions
- Intrinsic Procedures for Bit Operation and Representation
- QuickWin Library Routines
- Graphics Library Routines
- Portability Library Routines
- National Language Standard Library Routines
- POSIX* Library Routines
- Dialog Library Routines
- COM and Automation Library Routines
- Miscellaneous Run-Time Library Routines
- Functions Not Allowed as Actual Arguments

Statements for Program Unit Calls and Definitions

The following table lists statements used for program unit calls and definition.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK DATA</td>
<td>Identifies a block-data subprogram.</td>
</tr>
<tr>
<td>CALL</td>
<td>Executes a subroutine.</td>
</tr>
<tr>
<td>COMMON</td>
<td>Delineates variables shared between program units.</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Identifies start of a module within a host module.</td>
</tr>
<tr>
<td>ENTRY</td>
<td>Specifies a secondary entry point to a subroutine or external function.</td>
</tr>
<tr>
<td>EXTERNAL</td>
<td>Declares a user-defined subroutine or function to be passable as an argument.</td>
</tr>
<tr>
<td>FUNCTION</td>
<td>Identifies a program unit as a function.</td>
</tr>
<tr>
<td>INCLUDE</td>
<td>Inserts the contents of a specified file into the source file.</td>
</tr>
<tr>
<td>INTERFACE</td>
<td>Specifies an explicit interface for external functions and subroutines.</td>
</tr>
<tr>
<td>INTRINSIC</td>
<td>Declares a predefined function.</td>
</tr>
<tr>
<td>MODULE</td>
<td>Identifies a module program unit.</td>
</tr>
<tr>
<td>PROGRAM</td>
<td>Identifies a program unit as a main program.</td>
</tr>
<tr>
<td>RETURN</td>
<td>Returns control to the program unit that called a subroutine or function.</td>
</tr>
<tr>
<td>SUBROUTINE</td>
<td>Identifies a program unit as a subroutine.</td>
</tr>
<tr>
<td>USE</td>
<td>Gives a program unit access to a module.</td>
</tr>
</tbody>
</table>

**Statements Affecting Variables**

The following table lists statements that affect variable.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMATIC</td>
<td>Declares a variable on the stack, rather than at a static memory location.</td>
</tr>
<tr>
<td>BYTE</td>
<td>Specifies variables as the BYTE data type; BYTE is equivalent to INTEGER(1).</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>Specifies variables as the CHARACTER data type.</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>Specifies variables as the COMPLEX data type.</td>
</tr>
<tr>
<td>DATA</td>
<td>Assigns initial values to variables.</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>Identifies a variable as an array and specifies the number of elements.</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>Specifies variables as the DOUBLE COMPLEX data type, equivalent to COMPLEX(8).</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>Specifies variables as the DOUBLE-PRECISION real data type, equivalent to REAL(8).</td>
</tr>
<tr>
<td>EQUIVALENCE</td>
<td>Specifies that two or more variables or arrays share the same memory location.</td>
</tr>
<tr>
<td>IMPLICIT</td>
<td>Specifies the default typing for real and integer variables and functions.</td>
</tr>
<tr>
<td>INTEGER</td>
<td>Specifies variables as the INTEGER data type.</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>Specifies variables as the LOGICAL data type.</td>
</tr>
<tr>
<td>MAP</td>
<td>Within a UNION statement, delimits a group of variable type declarations that are to be ordered contiguously within memory.</td>
</tr>
<tr>
<td>NAMELIST</td>
<td>Declares a group name for a set of variables to be read or written in a single statement.</td>
</tr>
<tr>
<td>PARAMETER</td>
<td>Equates a constant expression with a name.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PROTECTED</td>
<td>Specifies limitations on the use of module entities.</td>
</tr>
<tr>
<td>REAL</td>
<td>Specifies variables as the REAL data type.</td>
</tr>
<tr>
<td>RECORD</td>
<td>Declares one or more variables of a user-defined structure type.</td>
</tr>
<tr>
<td>SAVE</td>
<td>Causes variables to retain their values between invocations of the procedure in which they are defined.</td>
</tr>
<tr>
<td>STATIC</td>
<td>Declares a variable is in a static memory location, rather than on the stack.</td>
</tr>
<tr>
<td>STRUCTURE</td>
<td>Defines a new variable type, composed of a collection of other variable types.</td>
</tr>
<tr>
<td>TYPE</td>
<td>Defines a new variable type, composed of a collection of other variable types.</td>
</tr>
<tr>
<td>UNION</td>
<td>Within a structure, causes two or more maps to occupy the same memory locations.</td>
</tr>
<tr>
<td>VOLATILE</td>
<td>Specifies that the value of an object is totally unpredictable based on information available to the current program unit.</td>
</tr>
</tbody>
</table>

**Statements for Input and Output**

The following table lists statements used for input and output.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCEPT</td>
<td>Statement</td>
<td>Similar to a formatted, sequential READ statement.</td>
</tr>
<tr>
<td>BACKSPACE</td>
<td>Statement</td>
<td>Positions a file to the beginning of the previous record.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>----------------</td>
<td>--------------------------------------------------------------</td>
</tr>
<tr>
<td>CLOSE</td>
<td>Statement</td>
<td>Disconnects the specified unit.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Statement</td>
<td>Deletes a record from a relative file.</td>
</tr>
<tr>
<td>ENDFILE</td>
<td>Statement</td>
<td>Writes an end-of-file record or truncates a file.</td>
</tr>
<tr>
<td>EOF</td>
<td>Intrinsic Function</td>
<td>Checks for end-of-file record. .TRUE. if at or past end-of-file.</td>
</tr>
<tr>
<td>INQUIRE</td>
<td>Statement</td>
<td>Returns the properties of a file or unit.</td>
</tr>
<tr>
<td>OPEN</td>
<td>Statement</td>
<td>Associates a unit number with an external device or file.</td>
</tr>
<tr>
<td>PRINT (or TYPE)</td>
<td>Statement</td>
<td>Displays data on the screen.</td>
</tr>
<tr>
<td>READ</td>
<td>Statement</td>
<td>Transfers data from a file to the items in an I/O list.</td>
</tr>
<tr>
<td>REWIND</td>
<td>Statement</td>
<td>Repositions a file to its first record.</td>
</tr>
<tr>
<td>REWRITE</td>
<td>Statement</td>
<td>Rewrites the current record.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Statement</td>
<td>Transfers data from the items in an I/O list to a file</td>
</tr>
</tbody>
</table>

**Compiler Directives**

The following table lists available compiler directives.

Each general directive name is preceded by the prefix `c`DEC$; for example, `c`DEC$ ALIAS. Each OpenMP* Fortran directive name is preceded by the prefix `c`$OMP; for example, `c`$OMP ATOMIC. The `c` in either can be a c, C, *, or ! in fixed-form source code; only ! in free-form source code.
### Table 697: General Directives

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALIAS</td>
<td>Specifies an alternate external name to be used when referring to external subprograms.</td>
</tr>
<tr>
<td>ASSUME_ALIGNED</td>
<td>Specifies that an entity in memory is aligned.</td>
</tr>
<tr>
<td>ATTRIBUTES</td>
<td>Applies attributes to variables and procedures.</td>
</tr>
<tr>
<td>DECLARE</td>
<td>Generates warning messages for undeclared variables.</td>
</tr>
<tr>
<td>DEFINE</td>
<td>Creates a variable whose existence can be tested during conditional compilation.</td>
</tr>
<tr>
<td>DISTRIBUTED POINT</td>
<td>Specifies distribution for a DO loop.</td>
</tr>
<tr>
<td>ELSE</td>
<td>Marks the beginning of an alternative conditional-compilation block to an IF directive construct.</td>
</tr>
<tr>
<td>ELSEIF</td>
<td>Marks the beginning of an alternative conditional-compilation block to an IF directive construct.</td>
</tr>
<tr>
<td>ENDIF</td>
<td>Marks the end of a conditional-compilation block.</td>
</tr>
<tr>
<td>FIXEDFORMAT</td>
<td>Sets fixed-form line length. This directive has no effect on freeform code.</td>
</tr>
<tr>
<td>FREEFORM</td>
<td>Uses freeform format for source code.</td>
</tr>
<tr>
<td>IDENT</td>
<td>Specifies an identifier for an object module.</td>
</tr>
<tr>
<td>IF</td>
<td>Marks the beginning of a conditional-compilation block.</td>
</tr>
<tr>
<td>IF DEFINED</td>
<td>Marks the beginning of a conditional-compilation block.</td>
</tr>
<tr>
<td>INTEGER</td>
<td>Selects default integer size.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IVDEP</td>
<td>Assists the compiler's dependence analysis of iterative DO loops.</td>
</tr>
<tr>
<td>LOOP COUNT</td>
<td>Specifies the loop count for a DO loop; this assists the optimizer.</td>
</tr>
<tr>
<td>MEMORYTOUCH(^1)</td>
<td>Ensures that a specific memory location is updated dynamically.</td>
</tr>
<tr>
<td>MEMREF_CONTROL(^1)</td>
<td>Lets you provide cache hints on prefetches, loads, and stores.</td>
</tr>
<tr>
<td>MESSAGE</td>
<td>Sends a character string to the standard output device.</td>
</tr>
<tr>
<td>NODEDECLARE</td>
<td>(Default) Turns off warning messages for undeclared variables.</td>
</tr>
<tr>
<td>NOFREEFORM</td>
<td>(Default) Uses standard FORTRAN 77 code formatting column rules.</td>
</tr>
<tr>
<td>NOPARALLEL</td>
<td>Disables auto-parallelization for an immediately following DO loop.</td>
</tr>
<tr>
<td>NOOPTIMIZE</td>
<td>Disables optimizations.</td>
</tr>
<tr>
<td>NOPREFetch</td>
<td>Disables a data prefetch from memory.</td>
</tr>
<tr>
<td>NOSTRICT</td>
<td>(Default) Disables a previous STRICT directive.</td>
</tr>
<tr>
<td>NOSWP(^1)</td>
<td>Disables software pipelining for a DO loop.</td>
</tr>
<tr>
<td>NOUNROLL</td>
<td>Disables the unrolling of a DO loop.</td>
</tr>
<tr>
<td>NOUNROLL_AND_JAM</td>
<td>Disables loop unrolling and jamming.</td>
</tr>
<tr>
<td>NOVECTOR(^2)</td>
<td>Disables vectorization of a DO loop.</td>
</tr>
<tr>
<td>OBJCOMMENT</td>
<td>Specifies a library search path in an object file.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OPTIMIZE</td>
<td>Enables optimizations.</td>
</tr>
<tr>
<td>OPTIONS</td>
<td>Controls whether fields in records and data items in common blocks are naturally aligned or packed on arbitrary byte boundaries.</td>
</tr>
<tr>
<td>PACK</td>
<td>Specifies the memory starting addresses of derived-type items.</td>
</tr>
<tr>
<td>PARALLEL</td>
<td>Enables auto-parallelization for an immediately following DO loop.</td>
</tr>
<tr>
<td>PREFETCH</td>
<td>Enables a data prefetch from memory.</td>
</tr>
<tr>
<td>PSECT</td>
<td>Modifies certain characteristics of a common block.</td>
</tr>
<tr>
<td>REAL</td>
<td>Selects default real size.</td>
</tr>
<tr>
<td>STRICT</td>
<td>Disables Intel® Fortran features not in the language standard specified on the command line (Fortran 95 or Fortran 90).</td>
</tr>
<tr>
<td>SWP(^1)</td>
<td>Enables software pipelining for a DO loop.</td>
</tr>
<tr>
<td>UNDEFINE</td>
<td>Removes a symbolic variable name created with the DEFINE directive.</td>
</tr>
<tr>
<td>UNROLL</td>
<td>Tells the compiler's optimizer how many times to unroll a DO loop.</td>
</tr>
<tr>
<td>UNROLL_AND_JAM</td>
<td>Enables loop unrolling and jamming.</td>
</tr>
<tr>
<td>VECTOR ALIGNED</td>
<td>Specifies that all data is aligned in a DO loop.</td>
</tr>
<tr>
<td>VECTOR ALWAYS</td>
<td>Enables vectorization of a DO loop.</td>
</tr>
<tr>
<td>VECTOR NONTEMPORAL(^2)</td>
<td>Directs the compiler to use non-temporal (that is, streaming) stores.</td>
</tr>
<tr>
<td>VECTOR NOVECTOR</td>
<td>Disables vectorization of a DO loop.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------</td>
</tr>
<tr>
<td>VECTOR TEMPORAL (^2)</td>
<td>Directs the compiler to use temporal (that is, non-streaming) stores.</td>
</tr>
<tr>
<td>VECTOR UNALIGNED</td>
<td>Specifies that no data is aligned in a DO loop.</td>
</tr>
</tbody>
</table>

\(^1\) i64 only  
\(^2\) i32, i64em

To use the following directives, you must specify compiler option `-openmp` (Linux and Mac OS X) or `/Qopenmp` (Windows).

**Table 698: OpenMP Fortran Directives**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATOMIC</td>
<td>Specifies that a specific memory location is to be updated dynamically.</td>
</tr>
<tr>
<td>BARRIER</td>
<td>Synchronizes all the threads in a team.</td>
</tr>
<tr>
<td>CRITICAL</td>
<td>Restricts access for a block of code to only one thread at a time.</td>
</tr>
<tr>
<td>DO</td>
<td>Specifies that the iterations of the immediately following DO loop must be executed in parallel.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Specifies synchronization points where the implementation must have a consistent view of memory.</td>
</tr>
<tr>
<td>MASTER</td>
<td>Specifies a block of code to be executed by the master thread of the team.</td>
</tr>
<tr>
<td>ORDERED</td>
<td>Specifies a block of code to be executed sequentially.</td>
</tr>
<tr>
<td>PARALLEL</td>
<td>Defines a parallel region.</td>
</tr>
<tr>
<td>PARALLEL DO</td>
<td>Defines a parallel region that contains a single DO directive.</td>
</tr>
</tbody>
</table>
### Program Control Statements and Procedures

The following table lists statements and a procedure that affect program control.

**Table 699: Statements**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE</td>
<td>Within a SELECT CASE structure, marks a block of statements that are executed if an associated value matches the SELECT CASE expression.</td>
</tr>
<tr>
<td>CONTINUE</td>
<td>Often used as the target of GOTO or as the terminal statement in a DO loop; performs no operation.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CYCLE</td>
<td>Advances control to the end statement of a DO loop; the intervening loop statements are not executed.</td>
</tr>
<tr>
<td>DO</td>
<td>Evaluates statements in the DO loop, through and including the ending statement, a specific number of times.</td>
</tr>
<tr>
<td>DO WHILE</td>
<td>Evaluates statements in the DO WHILE loop, through and including the ending statement, until a logical condition becomes .FALSE..</td>
</tr>
<tr>
<td>ELSE</td>
<td>Introduces an ELSE block.</td>
</tr>
<tr>
<td>ELSE IF</td>
<td>Introduces an ELSE IF block.</td>
</tr>
<tr>
<td>ELSEWHERE</td>
<td>Introduces an ELSEWHERE block.</td>
</tr>
<tr>
<td>END</td>
<td>Marks the end of a program unit.</td>
</tr>
<tr>
<td>END DO</td>
<td>Marks the end of a series of statements following a DO or DO WHILE statement.</td>
</tr>
<tr>
<td>END FORALL</td>
<td>Marks the end of a series of statements following a block FORALL statement.</td>
</tr>
<tr>
<td>END IF</td>
<td>Marks the end of a series of statements following a block IF statement.</td>
</tr>
<tr>
<td>END SELECT</td>
<td>Marks the end of a SELECT CASE statement.</td>
</tr>
<tr>
<td>END WHERE</td>
<td>Marks the end of a series of statements following a block WHERE statement.</td>
</tr>
<tr>
<td>EXIT</td>
<td>Leaves a DO loop; execution continues with the first statement that follows.</td>
</tr>
<tr>
<td>FORALL</td>
<td>Controls conditional execution of other statements.</td>
</tr>
<tr>
<td>GOTO</td>
<td>Transfers control to a specified part of the program.</td>
</tr>
</tbody>
</table>
### Controls conditional execution of other statements.

- **IF**
  - Controls conditional execution of other statements.

- **PAUSE**
  - Suspends program execution and, optionally, executes operating-system commands.

- **SELECT CASE**
  - Transfers program control to a block of statements, determined by a controlling argument.

- **STOP**
  - Terminates program execution.

- **WHERE**
  - Controls conditional execution of other statements.

### Table 700: Procedure

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXIT</td>
<td>(Intrinsic Subroutine) Terminates the program, flushes and closes all open files, and returns control to the operating system.</td>
</tr>
</tbody>
</table>

The portability routines RAISEQQ, SIGNALQQ, and SLEEPQQ also supply this functionality.

### Inquiry Intrinsic Functions

The following table lists inquiry intrinsic functions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Determines whether an allocatable array is allocated.</td>
</tr>
<tr>
<td>ASSOCIATED</td>
<td>Determines whether a the first pointer argument and the second (optional) pointer argument are associated.</td>
</tr>
<tr>
<td>BIT_SIZE</td>
<td>Returns the number of bits in an integer type.</td>
</tr>
<tr>
<td>CACHE_SIZE</td>
<td>Returns the size of a level of the memory cache.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>COMMAND_ARGUMENT_COUNT</td>
<td>Returns the number of command arguments.</td>
</tr>
<tr>
<td>DIGITS</td>
<td>Returns number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>EOF</td>
<td>Determines whether a file is at or beyond the end-of-file record.</td>
</tr>
<tr>
<td>EPSILON</td>
<td>Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.</td>
</tr>
<tr>
<td>HUGE</td>
<td>Returns the largest number that can be represented by numbers of type the argument.</td>
</tr>
<tr>
<td>IARGC</td>
<td>Returns the index of the last command-line argument.</td>
</tr>
<tr>
<td>INT_PTR_KIND</td>
<td>Returns the INTEGER KIND that will hold an address.</td>
</tr>
<tr>
<td>KIND</td>
<td>Returns the value of the kind parameter of the argument.</td>
</tr>
<tr>
<td>LBOUND</td>
<td>Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.</td>
</tr>
<tr>
<td>LEN</td>
<td>Returns the length of a character expression.</td>
</tr>
<tr>
<td>LOC</td>
<td>Returns the address of the argument.</td>
</tr>
<tr>
<td>MAXEXponent</td>
<td>Returns the largest positive decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>MINEXponent</td>
<td>Returns the largest negative decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NARGS</td>
<td>Returns the total number of command-line arguments, including the command.</td>
</tr>
<tr>
<td>PRECISION</td>
<td>Returns the number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>PRESENT</td>
<td>Determines whether an optional argument is present.</td>
</tr>
<tr>
<td>RADIX</td>
<td>Returns the base for data of the same type as the argument.</td>
</tr>
<tr>
<td>RANGE</td>
<td>Returns the decimal exponent range for data of the same type as the argument.</td>
</tr>
<tr>
<td>SELECTED_INT_KIND</td>
<td>Returns the value of the kind parameter of integers in range $x$.</td>
</tr>
<tr>
<td>SELECTED_REAL_KIND</td>
<td>Returns the value of the kind parameter of reals with (optional) first argument digits and (optional) second argument exponent range. At least one optional argument is required.</td>
</tr>
<tr>
<td>SHAPE</td>
<td>Returns the shape of an array or scalar argument.</td>
</tr>
<tr>
<td>SIZEOF</td>
<td>Returns the number of bytes of storage used by the argument.</td>
</tr>
<tr>
<td>TINY</td>
<td>Returns the smallest positive number that can be represented by numbers of type the argument.</td>
</tr>
<tr>
<td>UBOUND</td>
<td>Returns the upper bounds for all dimensions of an array, or the upper bound for a specified dimension.</td>
</tr>
</tbody>
</table>

**Random Number Intrinsic Procedures**

The following table lists random number intrinsic procedures.
Intrinsic function RAN
Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1.

Intrinsic subroutine RANDOM_NUMBER
Returns a pseudorandom real value greater than or equal to zero and less than one.

Intrinsic subroutine RANDOM_SEED
Changes the starting point of RANDOM_NUMBER; takes one or no arguments.

Intrinsic subroutine RANDU
Computes a pseudorandom number as a single-precision value.

The portability routines RANDOM and SEED also supply this functionality.

**Date and Time Intrinsic Subroutines**

The following table lists date and time intrinsic subroutines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU_TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the processor time in seconds.</td>
</tr>
<tr>
<td>DATE</td>
<td>Intrinsic subroutine</td>
<td>Returns the ASCII representation of the current date (in dd-mmm-yy form).</td>
</tr>
<tr>
<td>DATE_AND_TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the date and time. This is the preferred procedure for date and time.</td>
</tr>
<tr>
<td>IDATE</td>
<td>Intrinsic subroutine</td>
<td>Returns three integer values representing the current month, day, and year.</td>
</tr>
</tbody>
</table>
### Intrinsic subroutine SYSTEM_CLOCK

Intrinsic subroutine `SYSTEM_CLOCK` returns data from the system clock.

### Intrinsic subroutine TIME

Intrinsic subroutine `TIME` returns the ASCII representation of the current time (in hh:mm:ss form).

The portability routines `GETDAT`, `GETTIM`, `SETDAT`, and `SETTIM` also supply this functionality.

### Keyboard and Speaker Library Routines

The following table lists keyboard and speaker library routines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETCHARQQ</td>
<td>Run-time Function</td>
<td>Returns the next keyboard keystroke.</td>
</tr>
<tr>
<td>BEEPQQ</td>
<td>Portability subroutine</td>
<td>Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.</td>
</tr>
<tr>
<td>GETSTRQQ</td>
<td>Run-time function</td>
<td>Reads a character string from the keyboard using buffered input.</td>
</tr>
<tr>
<td>PEEKCHARQQ</td>
<td>Run-time function</td>
<td>Checks the buffer to see if a keystroke is waiting.</td>
</tr>
</tbody>
</table>

### Statements and Intrinsic Procedures for Memory Allocation and Deallocation

The following table lists statements and intrinsic procedures that are used for memory allocation and deallocation.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE</td>
<td>Statement</td>
<td>Dynamically establishes allocatable array dimensions.</td>
</tr>
</tbody>
</table>
The following table lists intrinsic functions for arrays.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Intrinsic Function</td>
<td>Determines whether an allocatable array is allocated.</td>
</tr>
<tr>
<td>DEALLOCATE</td>
<td>Statement</td>
<td>Frees the storage space previously reserved in an ALLOCATE statement.</td>
</tr>
<tr>
<td>FREE</td>
<td>Intrinsic Subroutine</td>
<td>Frees the memory block specified by the integer pointer argument.</td>
</tr>
<tr>
<td>MALLOC</td>
<td>Intrinsic Function</td>
<td>Allocates a memory block of size bytes and returns an integer pointer to the block.</td>
</tr>
<tr>
<td>MOVE_ALLOC</td>
<td>Intrinsic Subroutine</td>
<td>Moves an allocation from one allocatable object to another.</td>
</tr>
</tbody>
</table>

**Intrinsic Functions for Arrays**

Determines whether all array values meet the conditions in a mask along a (optional) dimension.

Determines whether any array values meet the conditions in a mask along a (optional) dimension.

Counts the number of array elements that meet the conditions in a mask along a (optional) dimension.

Performs a circular shift along a (optional) dimension.

Identifies a variable as an array and specifies the number of elements.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOT_PRODUCT</td>
<td>Performs dot-product multiplication on vectors (one-dimensional arrays).</td>
</tr>
<tr>
<td>EOSHIFT</td>
<td>Shifts elements off one end of array along a (optional) dimension and copies (optional) boundary values in other end.</td>
</tr>
<tr>
<td>LBOUND</td>
<td>Returns lower dimensional bounds of an array along a (optional) dimension.</td>
</tr>
<tr>
<td>MATMUL</td>
<td>Performs matrix multiplication on matrices (two-dimensional arrays).</td>
</tr>
<tr>
<td>MAXLOC</td>
<td>Returns the location of the maximum value in an array meeting conditions in a (optional) mask along a (optional) dimension.</td>
</tr>
<tr>
<td>MAXVAL</td>
<td>Returns the maximum value in an array along a (optional) dimension that meets conditions in a (optional) mask.</td>
</tr>
<tr>
<td>MERGE</td>
<td>Merges two arrays according to conditions in a mask.</td>
</tr>
<tr>
<td>MINLOC</td>
<td>Returns the location of the minimum value in an array meeting conditions in a (optional) mask along a (optional) dimension.</td>
</tr>
<tr>
<td>MINVAL</td>
<td>Returns the minimum value in an array along a (optional) dimension that meets conditions in a (optional) mask.</td>
</tr>
<tr>
<td>PACK</td>
<td>Packs an array into a vector (one-dimensional array) of an (optional) size using a mask.</td>
</tr>
<tr>
<td>PRODUCT</td>
<td>Returns product of elements of an array along a (optional) dimension that meet conditions in a (optional) mask.</td>
</tr>
<tr>
<td>RESHAPE</td>
<td>Reshapes an array with (optional) subscript order, padded with (optional) array elements.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>SHAPE</td>
<td>Returns the shape of an array.</td>
</tr>
<tr>
<td>SIZE</td>
<td>Returns the extent of an array along a (optional) dimension.</td>
</tr>
<tr>
<td>SPREAD</td>
<td>Replicates an array by adding a dimension.</td>
</tr>
<tr>
<td>SUM</td>
<td>Sums array elements along a (optional) dimension that meet conditions of an (optional) mask.</td>
</tr>
<tr>
<td>TRANSPOSE</td>
<td>Transposes a two-dimensional array.</td>
</tr>
<tr>
<td>UBOUND</td>
<td>Returns upper dimensional bounds of an array along a (optional) dimension.</td>
</tr>
<tr>
<td>UNPACK</td>
<td>Unpacks a vector (one-dimensional array) into an array under a mask padding with values from a field.</td>
</tr>
</tbody>
</table>

The DIMENSION statement identifies variables as arrays.

**Intrinsic Functions for Numeric and Type Conversion**

The following table lists intrinsic functions for numeric and type conversion.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS</td>
<td>Returns the absolute value of the argument.</td>
</tr>
<tr>
<td>AIMAG</td>
<td>Returns imaginary part of complex number $z$.</td>
</tr>
<tr>
<td>AINT</td>
<td>Truncates the argument to a whole number of a specified (optional) kind.</td>
</tr>
<tr>
<td>AMAX0</td>
<td>Returns largest value among integer arguments as real.</td>
</tr>
<tr>
<td>AMIN0</td>
<td>Returns smallest value among integer arguments as real.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ANINT</td>
<td>Rounds to the nearest whole number of a specified (optional) kind.</td>
</tr>
<tr>
<td>CEILING</td>
<td>Returns smallest integer greater than the argument.</td>
</tr>
<tr>
<td>CMPLX</td>
<td>Converts the first argument and (optional) second argument to complex of a (optional) kind.</td>
</tr>
<tr>
<td>CONJG</td>
<td>Returns the conjugate of a complex number.</td>
</tr>
<tr>
<td>DBLE</td>
<td>Converts the argument to double precision type.</td>
</tr>
<tr>
<td>DCMPLX</td>
<td>Converts the argument to double complex type.</td>
</tr>
<tr>
<td>DFLOAT</td>
<td>Converts an integer to double precision type.</td>
</tr>
<tr>
<td>DIM</td>
<td>Returns the first argument - the second argument if positive; else 0.</td>
</tr>
<tr>
<td>DPROD</td>
<td>Returns double-precision product of two single precision arguments.</td>
</tr>
<tr>
<td>FLOAT</td>
<td>Converts the argument to REAL(4).</td>
</tr>
<tr>
<td>FLOOR</td>
<td>Returns the greatest integer less than or equal to the argument.</td>
</tr>
<tr>
<td>IFIX</td>
<td>Converts a single-precision real argument to an integer argument by truncating.</td>
</tr>
<tr>
<td>IMAG</td>
<td>Same as AIMAG.</td>
</tr>
<tr>
<td>INT</td>
<td>Converts a value to integer type.</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>Converts between logical arguments of (optional) kind.</td>
</tr>
<tr>
<td>MAX</td>
<td>Returns largest value among arguments.</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
MAX1 | Returns largest value among real arguments as integer.
MIN | Returns smallest value among arguments.
MIN1 | Returns smallest value among real arguments as integer.
MOD | Returns the remainder of the first argument divided by the second argument.
MODULO | Returns the first argument modulo of the second argument.
NINT | Returns the nearest integer to the argument.
REAL | Converts a value to real type.
SIGN | Returns absolute value of the first argument times the sign of the second argument.
SNGL | Converts a double-precision argument to single-precision real type.
TRANSFER | Transforms first argument into type of second argument with (optional) size if an array.
ZEXT | Extends the argument with zeros.

### Trigonometric, Exponential, Root, and Logarithmic Intrinsic Procedures

The following table lists intrinsic procedures for trigonometric, exponential, root, and logarithmic operations.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACOS</td>
<td>Returns the arccosine of the argument, expressed in radians between 0 and pi.</td>
</tr>
<tr>
<td>ACOSD</td>
<td>Returns the arccosine of the argument, expressed in degrees between 0 and 180.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ALOG</td>
<td>Returns natural log of the argument.</td>
</tr>
<tr>
<td>ALOG10</td>
<td>Returns common log (base 10) of the argument.</td>
</tr>
<tr>
<td>ASIN</td>
<td>Returns the arcsine of the argument, expressed in radians between ±π/2.</td>
</tr>
<tr>
<td>ASIND</td>
<td>Returns the arcsine of the argument, expressed in degrees between ±90°.</td>
</tr>
<tr>
<td>ATAN</td>
<td>Returns the arctangent of the argument, expressed in radians between ±π/2.</td>
</tr>
<tr>
<td>ATAND</td>
<td>Returns the arctangent of the argument, expressed in degrees between ±90°.</td>
</tr>
<tr>
<td>ATAN2</td>
<td>Returns the arctangent of the first argument divided by the second argument, expressed in radians between ±π.</td>
</tr>
<tr>
<td>ATAN2D</td>
<td>Returns the arctangent of the first argument divided by the second argument, expressed in degrees between ±180°.</td>
</tr>
<tr>
<td>CCOS</td>
<td>Returns complex cosine of the argument.</td>
</tr>
<tr>
<td>CDCOS</td>
<td>Returns the double-precision complex cosine of the argument.</td>
</tr>
<tr>
<td>CDEXP</td>
<td>Returns double-precision complex exponential value of the argument.</td>
</tr>
<tr>
<td>CDLOG</td>
<td>Returns the double-precision complex natural log of the argument.</td>
</tr>
<tr>
<td>CDSIN</td>
<td>Returns the double-precision complex sine of the argument.</td>
</tr>
<tr>
<td>CDSQRT</td>
<td>Returns the double-precision complex square root of the argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CEXP</td>
<td>Returns the complex exponential value of the argument.</td>
</tr>
<tr>
<td>CLOG</td>
<td>Returns the complex natural log of the argument.</td>
</tr>
<tr>
<td>COS</td>
<td>Returns the cosine of the argument, which is in radians.</td>
</tr>
<tr>
<td>COSD</td>
<td><strong>COSD</strong>(x). Returns the cosine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>COSH</td>
<td>Returns the hyperbolic cosine of the argument.</td>
</tr>
<tr>
<td>COTAN</td>
<td>Returns the cotangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>COTAND</td>
<td>Returns the cotangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>CSIN</td>
<td>Returns the complex sine of the argument.</td>
</tr>
<tr>
<td>CSQRT</td>
<td>Returns the complex square root of the argument.</td>
</tr>
<tr>
<td>DACOS</td>
<td>Returns the double-precision arccosine of the argument radians between 0 and pi.</td>
</tr>
<tr>
<td>DACOSD</td>
<td>Returns the arccosine of the argument in degrees between 0 and 180.</td>
</tr>
<tr>
<td>DASIN</td>
<td>Returns the double-precision arcsine of the argument in radians between ±pi/2.</td>
</tr>
<tr>
<td>DASIND</td>
<td>Returns the double-precision arcsine of the argument degrees between ±90°.</td>
</tr>
<tr>
<td>DATAN</td>
<td>Returns the double-precision arctangent of the argument radians between ±pi/2.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DATAND</td>
<td>Returns the double-precision arctangent of the argument degrees between ±90°.</td>
</tr>
<tr>
<td>DATAN2</td>
<td>Returns the double-precision arctangent of the second argument divided by the first argument radians between ±pi.</td>
</tr>
<tr>
<td>DATAN2D</td>
<td>Returns the double-precision arctangent of the second argument divided by the first argument degrees between ±180°.</td>
</tr>
<tr>
<td>DCOS</td>
<td>Returns the double-precision cosine of the argument radians.</td>
</tr>
<tr>
<td>DCOSD</td>
<td>Returns the double-precision cosine of the argument degrees.</td>

<tr>
<td>DCOSH</td>
<td>Returns the double-precision hyperbolic cosine of the argument.</td>
</tr>
<tr>
<td>DCOTAN</td>
<td>Returns the double-precision cotangent of the argument.</td>
</tr>
<tr>
<td>DEXP</td>
<td>Returns the double-precision exponential value of the argument.</td>
</tr>
<tr>
<td>DLOG</td>
<td>Returns the double-precision natural log of the argument.</td>
</tr>
<tr>
<td>DLOG10</td>
<td>Returns the double-precision common log (base 10) of the argument.</td>
</tr>
<tr>
<td>DSIN</td>
<td>Returns the double-precision sin of the argument radians.</td>
</tr>
<tr>
<td>DSIND</td>
<td>Returns the double-precision sin of the argument degrees.</td>
</tr>
<tr>
<td>DSINH</td>
<td>Returns the double-precision hyperbolic sine of the argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DSQRT</td>
<td>Returns the double-precision square root of the argument.</td>
</tr>
<tr>
<td>DTAN</td>
<td>Returns the double-precision tangent of the argument radians.</td>
</tr>
<tr>
<td>DTAND</td>
<td>Returns the double-precision tangent of the argument degrees.</td>
</tr>
<tr>
<td>DTANH</td>
<td>Returns the double-precision hyperbolic tangent of the argument.</td>
</tr>
<tr>
<td>EXP</td>
<td>Returns the exponential value of the argument.</td>
</tr>
<tr>
<td>LOG</td>
<td>Returns the natural log of the argument.</td>
</tr>
<tr>
<td>LOG10</td>
<td>Returns the common log (base 10) of the argument.</td>
</tr>
<tr>
<td>SIN</td>
<td>Returns the sine of the argument, which is in radians.</td>
</tr>
<tr>
<td>SIND</td>
<td>Returns the sine of the argument, which is in degrees.</td>

</table>

**Intrinsic Functions for Floating-Point Inquiry and Control**

The following table lists intrinsic functions for floating-point inquiry and control.
Certain functions (EXPONENT, FRACTION, NEAREST, RRSPACING, SCALE, SET_EXPONENT and SPACING) return values related to components of the model set of real numbers. For a description of this model, see the Model for Real Data.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIGITS</td>
<td>Returns number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>EPSILON</td>
<td>Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.</td>
</tr>
<tr>
<td>EXPONENT</td>
<td>Returns the exponent part of the representation of $x$.</td>
</tr>
<tr>
<td>FRACTION</td>
<td>Returns the fractional part of the representation of the argument.</td>
</tr>
<tr>
<td>HUGE</td>
<td>Returns largest number that can be represented by data of type the argument.</td>
</tr>
<tr>
<td>MAXEXPONENT</td>
<td>Returns the largest positive decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>MINEXPONENT</td>
<td>Returns the largest negative decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>NEAREST</td>
<td>Returns the nearest different machine representable number to the first argument in the direction of the sign of the second argument.</td>
</tr>
<tr>
<td>PRECISION</td>
<td>Returns the number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>RADIX</td>
<td>Returns the base for data of the same type as the argument.</td>
</tr>
<tr>
<td>RANGE</td>
<td>Returns the decimal exponent range for data of the same type as the argument.</td>
</tr>
</tbody>
</table>
### Description

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RRSPACING</td>
<td>Returns the reciprocal of the relative spacing of numbers near the argument.</td>
</tr>
<tr>
<td>SCALE</td>
<td>Multiplies the first argument by 2 raised to the power of the second argument.</td>
</tr>
<tr>
<td>SET_EXPONENT</td>
<td>Returns a number whose fractional part is the first argument and whose exponential part is the second argument.</td>
</tr>
<tr>
<td>SPACING</td>
<td>Returns the absolute spacing of numbers near the argument.</td>
</tr>
<tr>
<td>TINY</td>
<td>Returns smallest positive number that can be represented by data of type of the argument.</td>
</tr>
</tbody>
</table>

The portability routines `GETCONTROLFPQQ`, `GETSTATUSFPQQ`, `LCWRQQ`, `SCWRQQ`, `SETCONTROLFPQQ`, and `SSWRQQ` also supply this functionality.

### Character Intrinsic Functions

The following table lists character intrinsic functions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACHAR</td>
<td>Returns character in a specified position in the ASCII character set.</td>
</tr>
<tr>
<td>ADJUSTL</td>
<td>Adjusts left, removing leading blanks and inserting trailing blanks.</td>
</tr>
<tr>
<td>ADJUSTR</td>
<td>Adjusts right, removing trailing blanks and inserting leading blanks.</td>
</tr>
<tr>
<td>CHAR</td>
<td>Returns character in a specified position in the processor's character set of (optional) kind.</td>
</tr>
<tr>
<td>IACHAR</td>
<td>Returns the position of the argument in the ASCII character set.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ICHAR</td>
<td>Returns the position of the argument in the processor’s character set.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Returns the starting position of a substring in a string, leftmost or (optional) rightmost occurrence.</td>
</tr>
<tr>
<td>LEN</td>
<td>Returns the size of the argument.</td>
</tr>
<tr>
<td>LEN_TRIM</td>
<td>Returns the number of characters in the argument, not counting trailing blanks.</td>
</tr>
<tr>
<td>LGE</td>
<td>Tests whether the first argument is greater than or equal to the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LGT</td>
<td>Tests whether the first argument is greater than the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LLE</td>
<td>Tests whether the first argument is less than or equal to the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LLT</td>
<td>Tests whether the first argument is less than the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>REPEAT</td>
<td>Concatenates multiple copies of a string.</td>
</tr>
<tr>
<td>SCAN</td>
<td>Scans a string for any characters in a set and returns leftmost or (optional) rightmost position where a match is found.</td>
</tr>
<tr>
<td>TRIM</td>
<td>Removes trailing blanks from a string.</td>
</tr>
<tr>
<td>VERIFY</td>
<td>Returns the position of the leftmost or (optional) rightmost character in the argument string not in a set, or zero if all characters in the set are present.</td>
</tr>
</tbody>
</table>
Intrinsic Procedures for Bit Operation and Representation

The following tables list intrinsic procedures for bit operation and representation.

**Table 711: Bit Operation**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIT_SIZE</td>
<td>Intrinsic Function</td>
<td>Returns the number of bits in integers of type the argument.</td>
</tr>
<tr>
<td>BTEST</td>
<td>Intrinsic Function</td>
<td>Tests a bit in a position of the argument; true if bit is 1.</td>
</tr>
<tr>
<td>IAND</td>
<td>Intrinsic Function</td>
<td>Performs a logical AND.</td>
</tr>
<tr>
<td>IBCHNG</td>
<td>Intrinsic Function</td>
<td>Reverses value of bit in a position of the argument.</td>
</tr>
<tr>
<td>IBCLR</td>
<td>Intrinsic Function</td>
<td>Clears the bit in a position of the argument to zero.</td>
</tr>
<tr>
<td>IBITS</td>
<td>Intrinsic Function</td>
<td>Extracts a sequence of bits of length from the argument starting in a position.</td>
</tr>
<tr>
<td>IBSET</td>
<td>Intrinsic Function</td>
<td>Sets the bit in a position of the argument to one.</td>
</tr>
<tr>
<td>IEOR</td>
<td>Intrinsic Function</td>
<td>Performs an exclusive OR.</td>
</tr>
<tr>
<td>IOR</td>
<td>Intrinsic Function</td>
<td>Performs an inclusive OR.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ISHA</td>
<td>Intrinsic Function</td>
<td>Shifts the argument arithmetically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from the right, ones shifted in from the left.</td>
</tr>
<tr>
<td>ISHC</td>
<td>Intrinsic Function</td>
<td>Performs a circular shift of the argument left or right by shift bits; left if shift positive, right if shift negative. No bits lost.</td>
</tr>
<tr>
<td>ISHFT</td>
<td>Intrinsic Function</td>
<td>Shifts the argument logically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from opposite end.</td>
</tr>
<tr>
<td>ISHFTC</td>
<td>Intrinsic Function</td>
<td>Performs a circular shift of the rightmost bits of (optional) size by shift bits. No bits lost.</td>
</tr>
<tr>
<td>ISHL</td>
<td>Intrinsic Function</td>
<td>Shifts the argument logically left or right by shift bits. Zeros shifted in from opposite end.</td>
</tr>
<tr>
<td>MVBITS</td>
<td>Intrinsic Subroutine</td>
<td>Copies a sequence of bits from one integer to another.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>NOT</td>
<td>Intrinsic Function</td>
<td>Performs a logical complement.</td>
</tr>
</tbody>
</table>

**Table 712: Bit Representation**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEADZ</td>
<td>Intrinsic Function</td>
<td>Returns leading zero bits in an integer.</td>
</tr>
<tr>
<td>POPCNT</td>
<td>Intrinsic Function</td>
<td>Returns number of 1 bits in an integer.</td>
</tr>
<tr>
<td>POPPAR</td>
<td>Intrinsic Function</td>
<td>Returns the parity of an integer.</td>
</tr>
<tr>
<td>TRAILZ</td>
<td>Intrinsic Function</td>
<td>Returns trailing zero bits in an integer.</td>
</tr>
</tbody>
</table>

**QuickWin Library Routines (W*32, W*64)**

The following table lists Quickwin library routines.

Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABOUTBOXQQ</td>
<td>Function</td>
<td>Adds an About Box with customized text.</td>
</tr>
<tr>
<td>APPENDMENUQQ</td>
<td>Function</td>
<td>Appends a menu item.</td>
</tr>
<tr>
<td>CLICKMENUQQ</td>
<td>Function</td>
<td>Sends menu click messages to the application window.</td>
</tr>
<tr>
<td>DELETEMENUQQ</td>
<td>Function</td>
<td>Deletes a menu item.</td>
</tr>
<tr>
<td>FOCUSQQ</td>
<td>Function</td>
<td>Makes a child window active, and gives focus to the child window.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------</td>
</tr>
<tr>
<td>GETACTIVEQQ</td>
<td>Function</td>
<td>Gets the unit number of the active child window.</td>
</tr>
<tr>
<td>GETEXITQQ</td>
<td>Function</td>
<td>Gets the setting for a QuickWin application's exit behavior.</td>
</tr>
<tr>
<td>GETHWNDQQ</td>
<td>Function</td>
<td>Gets the true windows handle from window with the specified unit number.</td>
</tr>
<tr>
<td>GETWINDOWCONFIG</td>
<td>Function</td>
<td>Returns the current window's properties.</td>
</tr>
<tr>
<td>GETWSIZEQQ</td>
<td>Function</td>
<td>Gets the size of the child or frame window.</td>
</tr>
<tr>
<td>GETUNITQQ</td>
<td>Function</td>
<td>Gets the unit number corresponding to the specified windows handle. Inverse of GETHWNDQQ.</td>
</tr>
<tr>
<td>INCHARQQ</td>
<td>Function</td>
<td>Reads a keyboard input and return its ASCII value.</td>
</tr>
<tr>
<td>INITIALSETTINGS</td>
<td>Function</td>
<td>Controls initial menu settings and initial frame window settings.</td>
</tr>
<tr>
<td>INQFOCUSQQ</td>
<td>Function</td>
<td>Determines which window is active and has the focus.</td>
</tr>
<tr>
<td>INSERTMENUQQ</td>
<td>Function</td>
<td>Inserts a menu item.</td>
</tr>
<tr>
<td>INTEGERTORGB</td>
<td>Subroutine</td>
<td>Converts a true color value into its red, green and blue components.</td>
</tr>
<tr>
<td>MESSAGEBOXQQ</td>
<td>Function</td>
<td>Displays a message box.</td>
</tr>
<tr>
<td>MODIFYMENUFLAGSQQ</td>
<td>Function</td>
<td>Modifies a menu item state.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MODIFYMENUROUTINEQQ</td>
<td>Function</td>
<td>Modifies a menu item's callback routine.</td>
</tr>
<tr>
<td>MODIFYMENUSTRINGQQ</td>
<td>Function</td>
<td>Changes a menu item's text string.</td>
</tr>
<tr>
<td>PASSDIRKEYSQQ</td>
<td>Function</td>
<td>Determines the behavior of direction and page keys.</td>
</tr>
<tr>
<td>REGISTERMOUSEEVENT</td>
<td>Function</td>
<td>Registers the application-defined routines to be called on mouse events.</td>
</tr>
<tr>
<td>RGBTOINTEGER</td>
<td>Function</td>
<td>Converts a trio of red, green and blue values to a true color value for use with RGB functions and subroutines.</td>
</tr>
<tr>
<td>SETACTIVEQQ</td>
<td>Function</td>
<td>Makes the specified window the current active window without giving it the focus.</td>
</tr>
<tr>
<td>SETEXITQQ</td>
<td>Function</td>
<td>Sets a QuickWin application's exit behavior.</td>
</tr>
<tr>
<td>SETMESSAGEQQ</td>
<td>Subroutine</td>
<td>Changes any QuickWin message, including status bar messages, state messages and dialog box messages.</td>
</tr>
<tr>
<td>SETMOUSECURSOR</td>
<td>Function</td>
<td>Sets the mouse cursor for the window in focus.</td>
</tr>
<tr>
<td>SETWINDOWCONFIG</td>
<td>Function</td>
<td>Configures the current window's properties.</td>
</tr>
<tr>
<td>SETWINDOWMENUQQ</td>
<td>Function</td>
<td>Sets the Window menu to which current child window names will be appended.</td>
</tr>
<tr>
<td>SETWSIZEQQ</td>
<td>Function</td>
<td>Sets the size of the child or frame window.</td>
</tr>
</tbody>
</table>
Routine Type | Description
---|---
Function | Removes the callback routine registered by REGISTERMOUSEEVENT.
Function | Blocks return until a mouse event occurs.

### Graphics Library Routines (W*32, W*64)

The following table lists library routines for graphics. Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARC, ARC_W</td>
<td>Functions</td>
<td>Draws an arc.</td>
</tr>
<tr>
<td>CLEARSCREEN</td>
<td>Subroutine</td>
<td>Clears the screen, viewport, or text window.</td>
</tr>
<tr>
<td>DISPLAYCURSOR</td>
<td>Function</td>
<td>Turns the cursor off and on.</td>
</tr>
<tr>
<td>ELLIPSE, ELLIPSE_W</td>
<td>Functions</td>
<td>Draws an ellipse or circle.</td>
</tr>
<tr>
<td>FLOODFILL, FLOODFILL_W</td>
<td>Functions</td>
<td>Fills an enclosed area of the screen with the current color index, using the current fill mask.</td>
</tr>
<tr>
<td>FLOODFILLRGB,</td>
<td>Functions</td>
<td>Fills an enclosed area of the screen with the current RGB color, using the current fill mask.</td>
</tr>
<tr>
<td>FLOODFILLRGB_W</td>
<td></td>
<td></td>
</tr>
<tr>
<td>GETARCINFO</td>
<td>Function</td>
<td>Determines the end points of the most recently drawn arc or pie.</td>
</tr>
<tr>
<td>GETBKCOLOR</td>
<td>Function</td>
<td>Returns the current background color index.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>--------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>GETBKCOLORRGB</td>
<td>Function</td>
<td>Returns the current background RGB color.</td>
</tr>
<tr>
<td>GETCOLOR</td>
<td>Function</td>
<td>Returns the current color index.</td>
</tr>
<tr>
<td>GETCOLORRGB</td>
<td>Function</td>
<td>Returns the current RGB color.</td>
</tr>
<tr>
<td>GETCURRENTPOSITION,</td>
<td>Subroutines</td>
<td>Returns the coordinates of the current graphics-output position.</td>
</tr>
<tr>
<td>GETCURRENTPOSITION_W</td>
<td></td>
<td></td>
</tr>
<tr>
<td>GETFILLMASK</td>
<td>Subroutine</td>
<td>Returns the current fill mask.</td>
</tr>
<tr>
<td>GETFONTINFO</td>
<td>Function</td>
<td>Returns the current font characteristics.</td>
</tr>
<tr>
<td>GETGTEXTEXTENT</td>
<td>Function</td>
<td>Determines the width of the specified text in the current font.</td>
</tr>
<tr>
<td>GETGTEXTROTATION</td>
<td>Function</td>
<td>Get the current text rotation angle.</td>
</tr>
<tr>
<td>GETIMAGE, GETIMAGE_W</td>
<td>Subroutines</td>
<td>Stores a screen image in memory.</td>
</tr>
<tr>
<td>GETLINESTYLE</td>
<td>Function</td>
<td>Returns the current line style.</td>
</tr>
<tr>
<td>GETPHYSCOORD</td>
<td>Subroutine</td>
<td>Converts viewport coordinates to physical coordinates.</td>
</tr>
<tr>
<td>GETPIXEL, GETPIXEL_W</td>
<td>Functions</td>
<td>Returns a pixel's color index.</td>
</tr>
<tr>
<td>GETPIXELRGB, GETPIXELRGB_W</td>
<td>Functions</td>
<td>Returns a pixel's RGB color.</td>
</tr>
<tr>
<td>GETPIXELS</td>
<td>Function</td>
<td>Returns the color indices of multiple pixels.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GETPIXELSRGB</td>
<td>Function</td>
<td>Returns the RGB colors of multiple pixels.</td>
</tr>
<tr>
<td>GETTEXTCOLOR</td>
<td>Function</td>
<td>Returns the current text color index.</td>
</tr>
<tr>
<td>GETTEXTCOLORRGB</td>
<td>Function</td>
<td>Returns the current text RGB color.</td>
</tr>
<tr>
<td>GETTEXTPOSITION</td>
<td>Subroutine</td>
<td>Returns the current text-output position.</td>
</tr>
<tr>
<td>GETTEXTWINDOW</td>
<td>Subroutine</td>
<td>Returns the boundaries of the current text window.</td>
</tr>
<tr>
<td>GETVIEWCOORD,</td>
<td>Subroutines</td>
<td>Converts physical or window coordinates to viewport coordinates.</td>
</tr>
<tr>
<td>GETVIEWCOORD_W</td>
<td></td>
<td></td>
</tr>
<tr>
<td>GETWINDOWCOORD</td>
<td>Subroutine</td>
<td>Converts viewport coordinates to window coordinates.</td>
</tr>
<tr>
<td>GETWRITEMODE</td>
<td>Function</td>
<td>Returns the logical write mode for lines.</td>
</tr>
<tr>
<td>GRSTATUS</td>
<td>Function</td>
<td>Returns the status (success or failure) of the most recently called graphics routine.</td>
</tr>
<tr>
<td>IMAGESIZE, IMAGESIZE_W</td>
<td>Functions</td>
<td>Returns image size in bytes.</td>
</tr>
<tr>
<td>INITIALIZEFONTS</td>
<td>Function</td>
<td>Initializes the font library.</td>
</tr>
<tr>
<td>LINETO, LINETO_W</td>
<td>Functions</td>
<td>Draws a line from the current position to a specified point.</td>
</tr>
<tr>
<td>LINETOAR</td>
<td>Function</td>
<td>Draws a line between points in one array and corresponding points in another array.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LINETOAREX</td>
<td>Function</td>
<td>Similar to LINETOAR, but also lets you specify color and line style.</td>
</tr>
<tr>
<td>LOADIMAGE, LOADIMAGE_W</td>
<td>Functions</td>
<td>Reads a Windows bitmap file (.BMP) and displays it at the specified location.</td>
</tr>
<tr>
<td>MOVETO, MOVETO_W</td>
<td>Subroutines</td>
<td>Moves the current position to the specified point.</td>
</tr>
<tr>
<td>OUTGTEXT</td>
<td>Subroutine</td>
<td>Sends text in the current font to the screen at the current position.</td>
</tr>
<tr>
<td>OUTTEXT</td>
<td>Subroutine</td>
<td>Sends text to the screen at the current position.</td>
</tr>
<tr>
<td>PIE, PIE_W</td>
<td>Functions</td>
<td>Draws a pie slice.</td>
</tr>
<tr>
<td>POLYBEZIER, POLYBEZIER_W</td>
<td>Functions</td>
<td>Draws one or more Bezier curves.</td>
</tr>
<tr>
<td>POLYBEZIERTO, POLYBEZIERTO_W</td>
<td>Functions</td>
<td>Draws one or more Bezier curves.</td>
</tr>
<tr>
<td>POLYGON, POLYGON_W</td>
<td>Functions</td>
<td>Draws a polygon.</td>
</tr>
<tr>
<td>POLYLINEQQ</td>
<td>Function</td>
<td>Draws a line between successive points in an array.</td>
</tr>
<tr>
<td>PUTIMAGE, PUTIMAGE_W</td>
<td>Subroutines</td>
<td>Retrieves an image from memory and displays it.</td>
</tr>
<tr>
<td>RECTANGLE, RECTANGLE_W</td>
<td>Functions</td>
<td>Draws a rectangle.</td>
</tr>
<tr>
<td>REMAPALLPALETTERGB</td>
<td>Function</td>
<td>Remaps a set of RGB color values to indices recognized by the current video configuration.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>REMAPPALETTERGB</td>
<td>Function</td>
<td>Remaps a single RGB color value to a color index.</td>
</tr>
<tr>
<td>SAVEIMAGE, SAVEIMAGE_W</td>
<td>Functions</td>
<td>Captures a screen image and saves it as a Windows bitmap file.</td>
</tr>
<tr>
<td>SCROLLTEXTWINDOW</td>
<td>Subroutine</td>
<td>Scrolls the contents of a text window.</td>
</tr>
<tr>
<td>SETBKCOLOR</td>
<td>Function</td>
<td>Sets the current background color.</td>
</tr>
<tr>
<td>SETBKCOLORRGB</td>
<td>Function</td>
<td>Sets the current background color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETCLIPRGN</td>
<td>Subroutine</td>
<td>Limits graphics output to a part of the screen.</td>
</tr>
<tr>
<td>SETCOLOR</td>
<td>Function</td>
<td>Sets the current color to a new color index.</td>
</tr>
<tr>
<td>SETCOLORRGB</td>
<td>Function</td>
<td>Sets the current color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETFILLMASK</td>
<td>Subroutine</td>
<td>Changes the current fill mask to a new pattern.</td>
</tr>
<tr>
<td>SETFONT</td>
<td>Function</td>
<td>Finds a single font matching the specified characteristics and assigns it to OUTGTEXT.</td>
</tr>
<tr>
<td>SETGTEXTROTATION</td>
<td>Subroutine</td>
<td>Sets the direction in which text is written to the specified angle.</td>
</tr>
<tr>
<td>SETLINESTYLE</td>
<td>Subroutine</td>
<td>Changes the current line style.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SETPIXEL, SETPIXEL_W</td>
<td>Functions</td>
<td>Sets color of a pixel at a specified location.</td>
</tr>
<tr>
<td>SETPIXELRGB, SETPIXELRGB_W</td>
<td>Functions</td>
<td>Sets RGB color of a pixel at a specified location.</td>
</tr>
<tr>
<td>SETPIXELS</td>
<td>Subroutine</td>
<td>Sets the color indices of multiple pixels.</td>
</tr>
<tr>
<td>SETPIXELSRGB</td>
<td>Subroutine</td>
<td>Sets the RGB color of multiple pixels.</td>
</tr>
<tr>
<td>SETTEXTCOLOR</td>
<td>Function</td>
<td>Sets the current text color to a new color index.</td>
</tr>
<tr>
<td>SETTEXTCOLORRGB</td>
<td>Function</td>
<td>Sets the current text color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETTEXTCURSOR</td>
<td>Function</td>
<td>Sets the height and width of the text cursor for the window in focus.</td>
</tr>
<tr>
<td>SETTEXTPosition</td>
<td>Subroutine</td>
<td>Changes the current text position.</td>
</tr>
<tr>
<td>SETTEXTWINDOW</td>
<td>Subroutine</td>
<td>Sets the current text display window.</td>
</tr>
<tr>
<td>SETVIEWORG</td>
<td>Subroutine</td>
<td>Positions the viewport coordinate origin.</td>
</tr>
<tr>
<td>SETVIEWPORT</td>
<td>Subroutine</td>
<td>Defines the size and screen position of the viewport.</td>
</tr>
<tr>
<td>SETWINDOW</td>
<td>Function</td>
<td>Defines the window coordinate system.</td>
</tr>
<tr>
<td>SETWRITEMODE</td>
<td>Function</td>
<td>Changes the current logical write mode for lines.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>WRAPON</td>
<td>Function</td>
<td>Turns line wrapping on or off.</td>
</tr>
</tbody>
</table>

**Portability Library Routines**

The following tables list library routines for portability.

Programs that use these routines must access the portability library with USE IFPORT.

**Table 715: Information Retrieval**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FSTAT</td>
<td>Function</td>
<td>Returns information about a logical file unit.</td>
</tr>
<tr>
<td>GETCWD</td>
<td>Function</td>
<td>Returns the pathname of the current working directory.</td>
</tr>
<tr>
<td>GETENV</td>
<td>Function</td>
<td>Searches the environment for a given string and returns its value if found.</td>
</tr>
<tr>
<td>GETGID</td>
<td>Function</td>
<td>Returns the group ID of the user.</td>
</tr>
<tr>
<td>GETLOG</td>
<td>Subroutine</td>
<td>Returns the user’s login name.</td>
</tr>
<tr>
<td>GETPID</td>
<td>Function</td>
<td>Returns the process ID of the process.</td>
</tr>
<tr>
<td>GETUID</td>
<td>Function</td>
<td>Returns the user ID of the user of the process.</td>
</tr>
<tr>
<td>HOSTNAM ¹</td>
<td>Function</td>
<td>Returns the name of the user’s host.</td>
</tr>
<tr>
<td>ISATTY</td>
<td>Function</td>
<td>Checks whether a logical unit number is a terminal.</td>
</tr>
</tbody>
</table>
### Table 716: Process Control

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSTAT</td>
<td>Function</td>
<td>Returns information about a named file. STAT is the preferred form of this function.</td>
</tr>
<tr>
<td>RENAME</td>
<td>Function</td>
<td>Renames a file.</td>
</tr>
<tr>
<td>STAT</td>
<td>Function</td>
<td>Returns information about a named file.</td>
</tr>
<tr>
<td>UNLINK</td>
<td>Function</td>
<td>Deletes the file given by path.</td>
</tr>
<tr>
<td>ABORT</td>
<td>Subroutine</td>
<td>Stops execution of the current process, clears I/O buffers, and writes a string to external unit 0.</td>
</tr>
<tr>
<td>ALARM</td>
<td>Function</td>
<td>Executes an external subroutine after waiting a specified number of seconds.</td>
</tr>
<tr>
<td>KILL</td>
<td>Function</td>
<td>Sends a signal code to the process given by ID.</td>
</tr>
<tr>
<td>SIGNAL</td>
<td>Function</td>
<td>Changes the action for signal.</td>
</tr>
<tr>
<td>SLEEP</td>
<td>Subroutine</td>
<td>Suspends program execution for a specified number of seconds.</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>Function</td>
<td>Executes a command in a separate shell.</td>
</tr>
</tbody>
</table>
### Table 717: Numeric Values and Conversion

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN</strong></td>
<td>Functions</td>
<td>Return single-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.</td>
</tr>
<tr>
<td><strong>BIC, BIS, BIT</strong></td>
<td>Subroutines</td>
<td>Perform bit level clear, set, and test for integers.</td>
</tr>
<tr>
<td><strong>CDFLOAT</strong></td>
<td>Function</td>
<td>Converts a COMPLEX(4) argument to DOUBLE PRECISION type.</td>
</tr>
<tr>
<td><strong>COMPLINT, COMPLREAL, COMPLLOG</strong></td>
<td>Functions</td>
<td>Return a BIT-WISE complement or logical .NOT. of the argument.</td>
</tr>
<tr>
<td><strong>CSMG</strong></td>
<td>Function</td>
<td>Performs an effective BIT-WISE store under mask.</td>
</tr>
<tr>
<td><strong>DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN</strong></td>
<td>Functions</td>
<td>Return double-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.</td>
</tr>
<tr>
<td><strong>DFLOATI, DFLOATJ, DFLOATK</strong></td>
<td>Functions</td>
<td>Convert an integer to double-precision real type.</td>
</tr>
<tr>
<td><strong>DRAND, DRANDM</strong></td>
<td>Functions</td>
<td>Return random numbers between 0.0 and 1.0.</td>
</tr>
<tr>
<td><strong>DRANSET</strong></td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td><strong>IDFLOAT</strong></td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to double-precision real type.</td>
</tr>
<tr>
<td><strong>IFLOATI, IFLOATJ</strong></td>
<td>Functions</td>
<td>Convert an integer to single-precision real type.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>INMAX</td>
<td>Function</td>
<td>Returns the maximum positive value for an integer.</td>
</tr>
<tr>
<td>INTC</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to INTEGER(2) type.</td>
</tr>
<tr>
<td>IRAND, IRANDM</td>
<td>Functions</td>
<td>Return a positive integer in the range 0 through 2<strong>31-1 or 2</strong>15-1 if called without an argument.</td>
</tr>
<tr>
<td>IRANGET</td>
<td>Subroutine</td>
<td>Returns the current seed.</td>
</tr>
<tr>
<td>IRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>JABS</td>
<td>Function</td>
<td>Computes an absolute value.</td>
</tr>
<tr>
<td>LONG</td>
<td>Function</td>
<td>Converts an INTEGER(2) argument to INTEGER(4) type.</td>
</tr>
<tr>
<td>QRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for a sequence of pseudo-random numbers.</td>
</tr>
<tr>
<td>RAND, RANDOM</td>
<td>Functions</td>
<td>Return random values in the range 0 through 1.0.</td>
</tr>
<tr>
<td>RANF</td>
<td>Function</td>
<td>Generates a random number between 0.0 and RAND_MAX.</td>
</tr>
<tr>
<td>RANGET</td>
<td>Subroutine</td>
<td>Returns the current seed.</td>
</tr>
<tr>
<td>RANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>SEED</td>
<td>Subroutine</td>
<td>Changes the starting point of RANDOM.</td>
</tr>
</tbody>
</table>
### Table 718: Input and Output

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHORT</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to INTEGER(2) type.</td>

<tr>
<td>SRAND</td>
<td>Subroutine</td>
<td>Seeds the random number generator used with IRAND and RAND.</td>
</tr>
<tr>
<td>ACCESS</td>
<td>Function</td>
<td>Checks a file for accessibility according to mode.</td>
</tr>
<tr>
<td>CHMOD</td>
<td>Function</td>
<td>Changes file attributes.</td>
</tr>
<tr>
<td>FGETC</td>
<td>Function</td>
<td>Reads a character from an external unit.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Subroutine</td>
<td>Flushes the buffer for an external unit to its associated file.</td>
</tr>
<tr>
<td>FPUTC</td>
<td>Function</td>
<td>Writes a character to an external unit.</td>
</tr>
<tr>
<td>FSEEK</td>
<td>Subroutine</td>
<td>Repositions a file on an external unit.</td>
</tr>
<tr>
<td>FTELL, FTELLI8</td>
<td>Function</td>
<td>Return the offset, in bytes, from the beginning of the file.</td>
</tr>
<tr>
<td>GETC</td>
<td>Function</td>
<td>Reads a character from unit 5.</td>
</tr>
<tr>
<td>GETPOS, GETPOSI8</td>
<td>Functions</td>
<td>Return the offset, in bytes, from the beginning of the file.</td>
</tr>
<tr>
<td>PUTC</td>
<td>Function</td>
<td>Writes a character to unit 6.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLOCK</td>
<td>Function</td>
<td>Returns current time in HH:MM:SS format using a 24-hour clock.</td>
</tr>
<tr>
<td>CLOCKX</td>
<td>Subroutine</td>
<td>Returns the processor clock to the nearest microsecond.</td>
</tr>
<tr>
<td>CTIME</td>
<td>Function</td>
<td>Converts system time to a 24-character ASCII string.</td>
</tr>
<tr>
<td>DATE</td>
<td>Subroutine or Function</td>
<td>Returns the current system date.</td>
</tr>
<tr>
<td>DATE4</td>
<td>Subroutine</td>
<td>Returns the current system date.</td>
</tr>
<tr>
<td>DCLOCK</td>
<td>Function</td>
<td>Returns the elapsed time in seconds since the start of the current process.</td>
</tr>
<tr>
<td>DTIME</td>
<td>Function</td>
<td>Returns CPU time since later of (1) start of program, or (2) most recent call to DTIME.</td>
</tr>
<tr>
<td>ETIME</td>
<td>Function</td>
<td>Returns elapsed CPU time since the start of program execution.</td>
</tr>
<tr>
<td>FDATE</td>
<td>Subroutine or Function</td>
<td>Returns the current date and time as an ASCII string.</td>
</tr>
<tr>
<td>GETDAT</td>
<td>Subroutine</td>
<td>Returns the date.</td>
</tr>
<tr>
<td>GETTIM</td>
<td>Subroutine</td>
<td>Returns the time.</td>
</tr>
<tr>
<td>GMTIME</td>
<td>Subroutine</td>
<td>Returns Greenwich Mean Time as a 9-element integer array.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>IDATE ^3</td>
<td>Subroutine</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>IDATE4</td>
<td>Subroutine</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>ITIME</td>
<td>Subroutine</td>
<td>Returns current time as a 3-element array (hour, minute, second).</td>
</tr>
<tr>
<td>JDATE ^3</td>
<td>Function</td>
<td>Returns current date as an 8-character string with the Julian date.</td>
</tr>
<tr>
<td>JDATE4</td>
<td>Function</td>
<td>Returns current date as a 10-character string with the Julian date.</td>
</tr>
<tr>
<td>LTIME</td>
<td>Subroutine</td>
<td>Returns local time as a 9-element integer array.</td>
</tr>
<tr>
<td>RTC</td>
<td>Function</td>
<td>Returns number of seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
<tr>
<td>SECNDS</td>
<td>Function</td>
<td>Returns number of seconds since midnight, less the value of its argument.</td>
</tr>
<tr>
<td>SETDAT</td>
<td>Function</td>
<td>Sets the date.</td>
</tr>
<tr>
<td>SETTIM</td>
<td>Function</td>
<td>Sets the time.</td>
</tr>
<tr>
<td>TIME</td>
<td>Subroutine or Function</td>
<td>As a subroutine, returns time formatted as HH:MM:SS; as a function, returns time in seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
</tbody>
</table>
### Table 720: Error Handling

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETLASTERROR</td>
<td>Function</td>
<td>Returns the last error set.</td>
</tr>
<tr>
<td>GETLASTERRORQQ</td>
<td>Function</td>
<td>Returns the last error set by a run-time function or subroutine.</td>
</tr>
<tr>
<td>IERRNO</td>
<td>Function</td>
<td>Returns the last code error.</td>
</tr>
<tr>
<td>SETERRORMODEQQ</td>
<td>Subroutine</td>
<td>Sets the mode for handling critical errors.</td>
</tr>
</tbody>
</table>

### Table 721: Program Control

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAISEQQ</td>
<td>Function</td>
<td>Sends an interrupt to the executing program, simulating an interrupt from the operating system.</td>
</tr>
<tr>
<td>RUNQQ</td>
<td>Function</td>
<td>Calls another program and waits for it to execute.</td>
</tr>
<tr>
<td>SIGNALQQ</td>
<td>Function</td>
<td>Controls signal handling.</td>
</tr>
<tr>
<td>SLEEPQQ</td>
<td>Subroutine</td>
<td>Delays execution of the program for the specified time.</td>
</tr>
</tbody>
</table>
Table 722: System, Drive, and Directory

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHDIR</td>
<td>Function</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>CHANGEDIRQQ</td>
<td>Function</td>
<td>Makes the specified directory the current (default) directory.</td>
</tr>
<tr>
<td>CHANGEDRIVEQQ</td>
<td>Function</td>
<td>Makes the specified drive the current drive.</td>
</tr>
<tr>
<td>DELDIRQQ</td>
<td>Function</td>
<td>Deletes a specified directory.</td>
</tr>
<tr>
<td>GETDRIVEDIRQQ</td>
<td>Function</td>
<td>Returns the current drive and directory path.</td>
</tr>
<tr>
<td>GETDRIVESIZEQQ</td>
<td>Function</td>
<td>Gets the size of the specified drive.</td>
</tr>
<tr>
<td>GETDRIVESQQ</td>
<td>Function</td>
<td>Reports the drives available to the system.</td>
</tr>
<tr>
<td>GETENVQQ</td>
<td>Function</td>
<td>Gets a value from the current environment.</td>
</tr>
<tr>
<td>MAKEDIRQQ</td>
<td>Function</td>
<td>Makes a directory with the specified directory name.</td>
</tr>
<tr>
<td>SETENVQQ</td>
<td>Function</td>
<td>Adds a new environment variable, or sets the value of an existing one.</td>
</tr>
<tr>
<td>SYSTEMQQ</td>
<td>Function</td>
<td>Executes a command by passing a command string to the operating system’s command interpreter.</td>
</tr>
</tbody>
</table>
### Table 723: Speaker

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEEPQQ</td>
<td>Subroutine</td>
<td>Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.</td>
</tr>
</tbody>
</table>

### Table 724: File Management

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DELFILESQQ</td>
<td>Function</td>
<td>Deletes the specified files in a specified directory.</td>
</tr>
<tr>
<td>FINDFILEQQ</td>
<td>Function</td>
<td>Searches for a file in the directories specified in the PATH environment variable.</td>
</tr>
<tr>
<td>FULLPATHQQ</td>
<td>Function</td>
<td>Returns the full path for a specified file or directory.</td>
</tr>
<tr>
<td>GETFILEINFOQQ</td>
<td>Function</td>
<td>Returns information about files with names that match a request string.</td>
</tr>
<tr>
<td>PACKTIMEQQ</td>
<td>Subroutine</td>
<td>Packs time values for use by SETFILETIMEQQ.</td>
</tr>
<tr>
<td>RENAMEFILEQQ</td>
<td>Function</td>
<td>Renames a file.</td>
</tr>
<tr>
<td>SETFILEACCESSQQ</td>
<td>Function</td>
<td>Sets file-access mode for the specified file.</td>
</tr>
<tr>
<td>SETFILETIMEQQ</td>
<td>Function</td>
<td>Sets modification time for a given file.</td>
</tr>
<tr>
<td>SPLITPATHQQ</td>
<td>Function</td>
<td>Breaks a full path into four components.</td>
</tr>
<tr>
<td>UNPACKTIMEQQ</td>
<td>Subroutine</td>
<td>Unpacks a file's packed time and date value into its component parts.</td>
</tr>
</tbody>
</table>
### Table 725: Arrays

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSEARCHQQ</td>
<td>Function</td>
<td>Performs a binary search for a specified element on a sorted one-dimensional array of non-structure data types (derived types are not allowed).</td>
</tr>
<tr>
<td>SORTQQ</td>
<td>Subroutine</td>
<td>Sorts a one-dimensional array of non-structure data types (derived types are not allowed).</td>
</tr>
</tbody>
</table>

### Table 726: Floating-Point Inquiry and Control

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLEARSTATUSFPQQ</td>
<td>Subroutine</td>
<td>Clears the exception flags in the floating-point processor status word.</td>
</tr>
<tr>
<td>GETCONTROLFPQQ</td>
<td>Subroutine</td>
<td>Returns the value of the floating-point processor control word.</td>
</tr>
<tr>
<td>GETSTATUSFPQQ</td>
<td>Subroutine</td>
<td>Returns the value of the floating-point processor status word.</td>
</tr>
<tr>
<td>LCWRQQ</td>
<td>Subroutine</td>
<td>Same as SETCONTROLFPQQ.</td>
</tr>
<tr>
<td>SCWRQQ</td>
<td>Subroutine</td>
<td>Same as GETCONTROLFPQQ.</td>
</tr>
<tr>
<td>SETCONTROLFPQQ</td>
<td>Subroutine</td>
<td>Sets the value of the floating-point processor control word.</td>
</tr>
<tr>
<td>SSWRQQ</td>
<td>Subroutine</td>
<td>Same as GETSTATUSFPQQ.</td>
</tr>
</tbody>
</table>
### Table 727: IEEE Functionality

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_FLAGS</td>
<td>Function</td>
<td>Sets, gets, or clears IEEE flags.</td>
</tr>
<tr>
<td>IEEE_HANDLER</td>
<td>Function</td>
<td>Establishes a handler for IEEE exceptions.</td>
</tr>
</tbody>
</table>

### Table 728: Serial Port I/O

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPORT_CANCEL_IO</td>
<td>Function</td>
<td>Cancels any I/O in progress to the specified port.</td>
</tr>
<tr>
<td>SPORT_CONNECT</td>
<td>Function</td>
<td>Establishes the connection to a serial port and defines certain usage parameters.</td>
</tr>
<tr>
<td>SPORT_CONNECT_EX</td>
<td>Function</td>
<td>Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception.</td>
</tr>
<tr>
<td>SPORT_GET_HANDLE</td>
<td>Function</td>
<td>Returns the Windows* handle associated with the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE</td>
<td>Function</td>
<td>Returns the baud rate, parity, data bits, and stop bit settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE_EX</td>
<td>Function</td>
<td>Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_TIMEOUTS</td>
<td>Function</td>
<td>Returns the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SPORT_PEEK_DATA</td>
<td>Function</td>
<td>Returns information about the availability of input data.</td>
</tr>
<tr>
<td>SPORT_PEEK_LINE</td>
<td>Function</td>
<td>Returns information about the availability of input records.</td>
</tr>
<tr>
<td>SPORT_PURGE</td>
<td>Function</td>
<td>Executes a purge function on the specified port.</td>
</tr>
<tr>
<td>SPORT_READ_DATA</td>
<td>Function</td>
<td>Reads available data from the port specified.</td>
</tr>
<tr>
<td>SPORT_READ_LINE</td>
<td>Function</td>
<td>Reads a record from the port specified.</td>
</tr>
<tr>
<td>SPORT_RELEASE</td>
<td>Function</td>
<td>Releases a serial port that has previously been connected.</td>
</tr>
<tr>
<td>SPORT_SET_STATE</td>
<td>Function</td>
<td>Sets the baud rate, parity, data bits and stop bit settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_STATE_EX</td>
<td>Function</td>
<td>Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_TIMEOUTS</td>
<td>Function</td>
<td>Sets the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>SPORT_SHOW_STATE</td>
<td>Function</td>
<td>Displays the state of a port.</td>
</tr>
<tr>
<td>SPORT_SPECIAL_FUNC</td>
<td>Function</td>
<td>Executes a communications function on a specified port.</td>
</tr>
<tr>
<td>SPORT_WRITE_DATA</td>
<td>Function</td>
<td>Outputs data to a specified port.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SPORT_WRITE_LINE</td>
<td>Function</td>
<td>Outputs data to a specified port and follows it with a record terminator.</td>
</tr>
</tbody>
</table>

**Table 729: Miscellaneous**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LNBLNK</td>
<td>Function</td>
<td>Returns the index of the last non-blank character in a string.</td>
</tr>
<tr>
<td>QSORT</td>
<td>Subroutine</td>
<td>Returns a sorted version of a one-dimensional array of a specified number of elements of a named size.</td>
</tr>
<tr>
<td>RINDEX</td>
<td>Function</td>
<td>Returns the index of the last occurrence of a substring in a string.</td>
</tr>
<tr>
<td>SCANENV</td>
<td>Subroutine</td>
<td>Scans the environment for the value of an environment variable.</td>
</tr>
<tr>
<td>TTYNAM</td>
<td>Function</td>
<td>Checks whether a logical unit is a terminal.</td>
</tr>
</tbody>
</table>

1 This routine can also be specified as HOSTNM.
2 There is also a RANDOM subroutine in the portability library.
3 The two-digit year return value of DATE, IDATE, and JDATE may cause problems with the year 2000. Use the intrinsic subroutine DATE_AND_TIME instead.
4 W*32, W*64

- Language Summary Tables

**National Language Support Library Routines (W*32, W*64)**

The following table lists library routines for National Language Support (NLS).
Programs that use these routines must access the NLS library with USE IFNLS. These routines are restricted to Windows* systems.

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MBCharLen</td>
<td>Function</td>
<td>Returns the length of the first multibyte character in a string.</td>
</tr>
<tr>
<td>MBConvertMBToUnicode</td>
<td>Function</td>
<td>Converts a character string from a multibyte codepage to a Unicode string.</td>
</tr>
<tr>
<td>MBConvertUnicodeToMB</td>
<td>Function</td>
<td>Converts a Unicode string to a multibyte character string of the current codepage.</td>
</tr>
<tr>
<td>MBCurMax</td>
<td>Function</td>
<td>Returns the longest possible multibyte character for the current codepage.</td>
</tr>
<tr>
<td>MBINCHARQQ</td>
<td>Function</td>
<td>Same as INCHARQQ, but can read a single multibyte character at once.</td>
</tr>
<tr>
<td>MBINDEX</td>
<td>Function</td>
<td>Same as INDEX, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>MBJISToJMS</td>
<td>Function</td>
<td>Converts a Japan Industry Standard (JIS) character to a Kanji (Shift JIS or JMS) character.</td>
</tr>
<tr>
<td>MBJMSToJIS</td>
<td>Function</td>
<td>Converts a Kanji (Shift JIS or JMS) character to a Japan Industry Standard (JIS) character.</td>
</tr>
<tr>
<td>MBLead</td>
<td>Function</td>
<td>Determines whether a given character is the first byte of a multibyte character.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MBLen</td>
<td>Function</td>
<td>Returns the number of multibyte characters in a string, including trailing spaces.</td>
</tr>
<tr>
<td>MBLen_Trim</td>
<td>Function</td>
<td>Returns the number of multibyte characters in a string, not including trailing spaces.</td>
</tr>
<tr>
<td>MBLGE, MBLGT, MBLLE, MBLLT, MBLEQ, MBLNE</td>
<td>Function</td>
<td>Same as LGE, LGT, LLE, and LLT, and the logical operators .EQ. and .NE., except that multibyte characters can be included in their arguments.</td>
</tr>
<tr>
<td>MBNext</td>
<td>Function</td>
<td>Returns the string position of the first byte of the multibyte character immediately after the given string position.</td>
</tr>
<tr>
<td>MBPrev</td>
<td>Function</td>
<td>Returns the string position of the first byte of the multibyte character immediately before the given string position.</td>
</tr>
<tr>
<td>MBSCAN</td>
<td>Function</td>
<td>Same as SCAN, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>MBStrLead</td>
<td>Function</td>
<td>Performs a context sensitive test to determine whether a given byte in a character string is a lead byte.</td>
</tr>
<tr>
<td>MBVERIFY</td>
<td>Function</td>
<td>Same as VERIFY, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>NLSEnumCodepages</td>
<td>Function</td>
<td>Returns an array of valid codepages for the current console.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NLSEnumLocales</td>
<td>Function</td>
<td>Returns an array of locales (language/country combinations) installed on the system.</td>
</tr>
<tr>
<td>NLSFormatCurrency</td>
<td>Function</td>
<td>Formats a currency number according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatDate</td>
<td>Function</td>
<td>Formats a date according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatNumber</td>
<td>Function</td>
<td>Formats a number according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatTime</td>
<td>Function</td>
<td>Formats a time according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSGetEnvironmentCodepage</td>
<td>Function</td>
<td>Returns the current codepage for the system Window or console.</td>
</tr>
<tr>
<td>NLSGetLocale</td>
<td>Subroutine</td>
<td>Returns the current language, country, and/or codepage.</td>
</tr>
<tr>
<td>NLSGetLocaleInfo</td>
<td>Function</td>
<td>Returns information about the current locale.</td>
</tr>
<tr>
<td>NLSSetEnvironmentCodepage</td>
<td>Function</td>
<td>Sets the codepage for the console.</td>
</tr>
<tr>
<td>NLSSetLocale</td>
<td>Function</td>
<td>Sets the current language, country, and codepage.</td>
</tr>
</tbody>
</table>

**POSIX* Library Procedures**

The following table lists library procedures for POSIX*. 
Programs that use POSIX procedures must access the appropriate libraries with USE IFPOSIX. The IPX \textit{nnnn} routines are functions; the PXF \textit{nnnn} routines are subroutines, except for the routines named PXFIS \textit{nnnn} and PXFWIF \textit{nnnn}.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPXFARGC</td>
<td>Returns the index of the last command-line argument.</td>
</tr>
<tr>
<td>IPXFCONST</td>
<td>Returns the value associated with a constant defined in the C POSIX standard.</td>
</tr>
<tr>
<td>IPXFLENTTRIM</td>
<td>Returns the index of the last non-blank character in an input string.</td>
</tr>
<tr>
<td>IPXFEXITSTATUS(^1)</td>
<td>Returns the exit code of a child process.</td>
</tr>
<tr>
<td>IPXFWSTOPSIG (^1)</td>
<td>Returns the number of the signal that caused a child process to stop.</td>
</tr>
<tr>
<td>IPXFWTERMSIG (^1)</td>
<td>Returns the number of the signal that caused a child process to terminate.</td>
</tr>
<tr>
<td>PXF(type)GET</td>
<td>Gets the value stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXF(type)SET</td>
<td>Sets the value of a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA(type)GET</td>
<td>Gets the array values stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA(type)SET</td>
<td>Sets the value of an array component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFACCESS</td>
<td>Determines the accessibility of a file.</td>
</tr>
<tr>
<td>PXFALARM</td>
<td>Schedules an alarm.</td>
</tr>
<tr>
<td>PXFCALLSUBLENDLE</td>
<td>Calls the associated subroutine.</td>
</tr>
<tr>
<td>PXFCFGETISPEED (^1)</td>
<td>Returns the input baud rate from a \textit{termios} structure.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFCFGETOSPEED</td>
<td>Returns the output baud rate from a termios structure.</td>
</tr>
<tr>
<td>PXFCFSETISPEED</td>
<td>Sets the input baud rate in a termios structure.</td>
</tr>
<tr>
<td>PXFCFSETOSPEED</td>
<td>Sets the output baud rate in a termios structure.</td>
</tr>
<tr>
<td>PXFCHDIR</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>PXFCHMOD</td>
<td>Changes the ownership mode of the file.</td>
</tr>
<tr>
<td>PXFCHOWN</td>
<td>Changes the owner and group of a file.</td>
</tr>
<tr>
<td>PXFCLEARENT</td>
<td>Clears the process environment.</td>
</tr>
<tr>
<td>PXFCLOSE</td>
<td>Closes the file associated with the descriptor.</td>
</tr>
<tr>
<td>PXFCLOSEDIR</td>
<td>Closes the directory stream.</td>
</tr>
<tr>
<td>PXFCNTL</td>
<td>Manipulates an open file descriptor.</td>
</tr>
<tr>
<td>PXFCONST</td>
<td>Returns the value associated with a constant.</td>
</tr>
<tr>
<td>PXFCREAT</td>
<td>Creates a new file or rewrites an existing file.</td>
</tr>
<tr>
<td>PXFCTERMID</td>
<td>Generates a terminal pathname.</td>
</tr>
<tr>
<td>PXFDUP, PXFDUP2</td>
<td>Duplicates an existing file descriptor.</td>
</tr>
<tr>
<td>PXFE(type)GET</td>
<td>Gets the value stored in an array element component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFE(type)SET</td>
<td>Sets the value of an array element component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFEXECV, PXFEXECVE, PXFEXECVP</td>
<td>Executes a new process by passing command-line arguments.</td>
</tr>
<tr>
<td>PXFEXIT, PXFFASTEXIT</td>
<td>Exits from a process.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFFDOPEN</td>
<td>Opens an external unit.</td>
</tr>
<tr>
<td>PXFFFLUSH</td>
<td>Flushes a file directly to disk.</td>
</tr>
<tr>
<td>PXFFGETC</td>
<td>Reads a character from a file.</td>
</tr>
<tr>
<td>PXFFILENO</td>
<td>Returns the file descriptor associated with a specified unit.</td>
</tr>
<tr>
<td>PXFFORK</td>
<td>Creates a child process that differs from the parent process only in its PID.</td>
</tr>
<tr>
<td>PXFFPATHCONF</td>
<td>Gets the value for a configuration option of an opened file.</td>
</tr>
<tr>
<td>PXFFPUTC</td>
<td>Writes a character to a file.</td>
</tr>
<tr>
<td>PXFFSEEK</td>
<td>Modifies a file position.</td>
</tr>
<tr>
<td>PXFFSTAT</td>
<td>Gets a file's status information.</td>
</tr>
<tr>
<td>PXFFTELL</td>
<td>Returns the relative position in bytes from the beginning of the file.</td>
</tr>
<tr>
<td>PXFGETARG</td>
<td>Gets the specified command-line argument.</td>
</tr>
<tr>
<td>PXFGETATTY</td>
<td>Tests whether a file descriptor is connected to a terminal.</td>
</tr>
<tr>
<td>PXFGETC</td>
<td>Reads a character from standard input unit 5.</td>
</tr>
<tr>
<td>PXFGETCWD</td>
<td>Returns the path of the current working directory.</td>
</tr>
<tr>
<td>PXFGETEGID</td>
<td>Gets the effective group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETENV</td>
<td>Gets the setting of an environment variable.</td>
</tr>
<tr>
<td>PXFGETEUID</td>
<td>Gets the effective user ID of the current process.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>PXFGETGID 1</td>
<td>Gets the real group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETGRGID 1</td>
<td>Gets group information for the specified GID.</td>
</tr>
<tr>
<td>PXFGETGRNAM 1</td>
<td>Gets group information for the named group.</td>
</tr>
<tr>
<td>PXFGETGROUPS 1</td>
<td>Gets supplementary group IDs.</td>
</tr>
<tr>
<td>PXFGETLOGIN</td>
<td>Gets the name of the user.</td>
</tr>
<tr>
<td>PXFGETPGRP 1</td>
<td>Gets the process group ID of the calling process.</td>
</tr>
<tr>
<td>PXFGETPID</td>
<td>Gets the process ID of the calling process.</td>
</tr>
<tr>
<td>PXFGETPPID</td>
<td>Gets the process ID of the parent of the calling process.</td>
</tr>
<tr>
<td>PXFGETPWNAM 1</td>
<td>Gets password information for a specified name.</td>
</tr>
<tr>
<td>PXFGETPWUID 1</td>
<td>Gets password information for a specified UID.</td>
</tr>
<tr>
<td>PXFGETSUBHANDLE</td>
<td>Returns a subroutine handle for a subroutine.</td>
</tr>
<tr>
<td>PXFGETUID 1</td>
<td>Gets the real user ID of the current process.</td>
</tr>
<tr>
<td>PXFISBLK</td>
<td>Tests for a block special file.</td>
</tr>
<tr>
<td>PXFISCHR</td>
<td>Tests for a character file.</td>
</tr>
<tr>
<td>PXFISCONST</td>
<td>Tests whether a string is a valid constant name.</td>
</tr>
<tr>
<td>PXFISDIR</td>
<td>Tests whether a file is a directory.</td>
</tr>
<tr>
<td>PXFISFIFO</td>
<td>Tests whether a file is a special FIFO file.</td>
</tr>
<tr>
<td>PXFISREG</td>
<td>Tests whether a file is a regular file.</td>
</tr>
<tr>
<td>PXFKILL</td>
<td>Sends a signal to a specified process.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFLINK</td>
<td>Creates a link to a file or directory.</td>
</tr>
<tr>
<td>PXFLOCALTIME</td>
<td>Converts a given elapsed time in seconds to local time.</td>
</tr>
<tr>
<td>PXFLSEEK</td>
<td>Positions a file a specified distance in bytes.</td>
</tr>
<tr>
<td>PXFMKDIR</td>
<td>Creates a new directory.</td>
</tr>
<tr>
<td>PXFMKFIFO</td>
<td>Creates a new FIFO.</td>
</tr>
<tr>
<td>PXFOPEN</td>
<td>Opens or creates a file.</td>

**COM and Automation Library Routines (W*32, W*64)**

The following tables list COM and Automation library routines.

Programs that use COM routines must access the appropriate libraries with USE IFCOM. Programs that use automation routines must access the appropriate libraries with USE IFAUTO. Some procedures also require the USE IFWINTY module.

The COM and Automation routines are restricted to Windows* systems.

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

**Table 733: Component Object Model (COM) Procedures (USE IFCOM)**

<td>Checks the buffer to see if a keystroke is waiting.</td>
</tr>
</tbody>
</table>
### Description

PERROR

Subroutine

**Description**

Sends a message to the standard error stream, preceded by a specified string, for the last detected error.

TRACEBACKQQ

Subroutine

**Description**

Provides traceback information.

---

**1 W*32, W*64**

---

### Intrinsic Functions Not Allowed as Actual Arguments

This table is now located in Intrinsic Procedures.

---

### A to B

**ABORT**

**Portability Subroutine:** Flushing and closing I/O buffers, and terminates program execution.

---

**Module**

USE IFPORT

---

**Syntax**

CALL ABORT[string]

*string* (Input; optional) Character*(*). Allows you to specify an abort message at program termination. When ABORT is called, "abort:" is written to external unit 0, followed by *string*. If omitted, the default message written to external unit 0 is "abort: Fortran Abort Called."

This subroutine causes the program to terminate and an exit code value of 134 is returned to the program that launched it.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
!The following prints "abort: Fortran Abort Called"
CALL ABORT
!The following prints "abort: Out of here!"
Call ABORT ("Out of here!")

See Also
• A to B
• EXIT
• STOP

ABOUTBOXQQ (W*32, W*64)
QuickWin Function: Specifies the information displayed in the message box that appears when the user selects the About command from a QuickWin application's Help menu.

Module
USE IFQWIN

Syntax
result=ABOUTBOXQQ(cstring)
cstring (Input; output) Character*(*) Null-terminated C string.

Results
The value of the result is INTEGER(4). It is zero if successful; otherwise, nonzero.
If your program does not call ABOUTBOXQQ, the QuickWin run-time library supplies a default string.

Compatibility
QUICKWIN GRAPHICS LIB
Example

USE IFQWIN
INTEGER(4) dummy
!
Set the About box message

dummy = ABOUTBOXQQ ('Matrix Multiplier\r
      Version 1.0'C)

ABS

Elemental Intrinsic Function (Generic):
Computes an absolute value.

Syntax

result = ABS(a)

a

(Input) Must be of type integer, real, or complex.

Results

The result has the same type and kind type parameter as a except if a is complex value, the result type is real. If a is an integer or real value, the value of the result is | a |; if a is a complex value (X, Y), the result is the real value SQRT (X**2 + Y**2).

<table>

<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>CQABS</td>
<td>COMPLEX(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

<sup>1</sup> Or HABS.

<sup>2</sup> Or JIABS. For compatibility with older versions of Fortran, IABS can also be specified as a generic function.

<sup>3</sup> The setting of compiler options specifying real size can affect CABS.

<sup>4</sup> This function can also be specified as ZABS.

**Example**

ABS (-7.4) has the value 7.4.

ABS ((6.0, 8.0)) has the value 10.0.

The following ABS.F90 program calculates two square roots, retaining the sign:

```fortran
REAL mag(2), sgn(2), result(2)
WRITE (*, '(A)') ' Enter two signed magnitudes: '
READ (*, *) mag
sgn = SIGN((/1.0, 1.0/), mag) ! transfer the signs to 1.0s
result = SQRT (ABS (mag))
! Restore the sign by multiplying by -1 or +1:
result = result * sgn
WRITE (*, *) result
END
```
**ACCEPT**

*Statement:* Transfers input data.

**Syntax**

*Formatted:*

```plaintext
ACCEPT form[,io-list]
```

*Formatted - List-Directed:*

```plaintext
ACCEPT*[,io-list]
```

*Formatted - Namelist:*

```plaintext
ACCEPTnml
```

- `form` Is the nonkeyword form of a format specifier (no FMT=).
- `io-list` Is an I/O list.
- `*` Is the format specifier indicating list-directed formatting.
- `nml` Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.

The ACCEPT statement is the same as a formatted, sequential READ statement, except that an ACCEPT statement must never be connected to user-specified I/O units. You can override this restriction by using an environment variable.

**Example**

In the following example, character data is read from the implicit unit and binary values are assigned to each of the five elements of array CHARAR:

```plaintext
CHARACTER*10 CHARAR(5)

ACCEPT 200, CHARAR

200 FORMAT (5A10)
```

**See Also**

- A to B

*Building Applications: Logical Devices*
**ACCESS Function**

*Portability Function*: Determines if a file exists and how it can be accessed.

**Module**

USE IFPORT

**Syntax**

```fortran
result = ACCESS(name, mode)
```

- **name** *(Input) Character*(*)*. Name of the file whose accessibility is to be determined.
- **mode** *(Input) Character*(*)*. Modes of accessibility to check for. Must be a character string of length one or greater containing only the characters "r", "w", "x", or "" (a blank). These characters are interpreted as follows.

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
<td>Tests for read permission</td>
</tr>
<tr>
<td>w</td>
<td>Tests for write permission</td>
</tr>
<tr>
<td>x</td>
<td>Tests for execute permission. On Windows* systems, the extension of <em>name</em> must be *.COM, .EXE, .BAT, .CMD, .PL, .KSH, or .CSH.</td>
</tr>
<tr>
<td>(blank)</td>
<td>Tests for existence</td>
</tr>
</tbody>
</table>

The characters within **mode** can appear in any order or combination. For example, wrx and r are legal forms of **mode** and represent the same set of inquiries.

**Results**

The value of the result is INTEGER(4). It is zero if all inquiries specified by **mode** are true. If either argument is invalid, or if the file cannot be accessed in all of the modes specified, one of the following error codes is returned:
• **EACCESS**: Access denied; the file's permission setting does not allow the specified access
• **EINVAL**: The mode argument is invalid
• **ENOENT**: File or path not found

For a list of error codes, see IERRNO.

The *name* argument can contain either forward or backward slashes for path separators.

On Windows* systems, all files are readable. A test for read permission always returns 0.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
! checks for read and write permission on the file "DATAFILE.TXT"
J = ACCESS ("DATAFILE.TXT", "rw")
PRINT *, J

! checks whether "DATAFILE.TXT" is executable. It is not, since
! it does not end in .COM, .EXE, .BAT, or .CMD
J = ACCESS ("DATAFILE.TXT", "x")
PRINT *, J
```

**ACHAR**

**Elemental Intrinsic Function (Generic):**

*Returns the character in a specified position of the ASCII character set, even if the processor's default character set is different. It is the inverse of the IACHAR function. In Intel © Fortran, ACHAR is equivalent to the CHAR function.***

**Syntax**

```fortran
result = ACHAR (i [, kind])
```
ACHAR (IACHAR(C)) has the value C for any character C capable of representation in the default character set. For a complete list of ASCII character codes, see Character and Key Code Charts.

Example

ACHAR (71) has the value 'G'.

ACHAR (63) has the value '?.

See Also

• A to B
• CHAR
• IACHAR
• ICHAR

ACOS

Elemental Intrinsic Function (Generic):

Produces the arccosine of \( x \).

Syntax

\[
\text{result} = \text{ACOS} (x)
\]

\( x \) (Input) Must be of type real. The \(| x |\) must be less than or equal to 1.

Results

The result type is the same as \( x \) and is expressed in radians. The value lies in the range 0 to \( \pi \).
ACOS

Elemental Intrinsic Function (Generic):

Produces the arccosine of $x$.

**Syntax**

```
result = ACOS(x)
```

$x$ (Input) Must be of type real. The $|x|$ must be less than or equal to 1.

**Results**

The result type is the same as $x$ and is expressed in degrees. The value lies in the range $-90$ to $90$ degrees.

### Specific Name | Argument Type | Result Type
--- | --- | ---
ACOS | REAL(4) | REAL(4)
DACOS | REAL(8) | REAL(8)
QACOS$^1$ | REAL(16) | REAL(16)

$^1$Or QARCOS.

**Example**

ACOS (0.68032123) has the value .8225955.

ACOSD

**Elemental Intrinsic Function (Generic):**

Produces the arccosine of $x$.

**Syntax**

```
result = ACOSD(x)
```

$x$ (Input) Must be of type real. The $|x|$ must be less than or equal to 1.

**Results**

The result type is the same as $x$ and is expressed in degrees. The value lies in the range $-90$ to $90$ degrees.

### Specific Name | Argument Type | Result Type
--- | --- | ---
ACOSD | REAL(4) | REAL(4)
DACOSD | REAL(8) | REAL(8)
QACOSD | REAL(16) | REAL(16)

**Example**

ACOSD (0.886579) has the value 27.55354.
ACOSH

Elemental Intrinsic Function (Generic):
Produces the hyperbolic arccosine of \( x \).

Syntax

\[
\text{result} = \text{ACOSH} (\text{x})
\]

\( x \) (Input) Must be of type real and must be greater than or equal to 1.

Results

The result type is the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACOSH</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DACOSH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QACOSH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

ACOSH (1.0) has the value 0.0.
ACOSH (180.0) has the value 5.8861.

ADJUSTL

Elemental Intrinsic Function (Generic): Adjusts a character string to the left, removing leading blanks and inserting trailing blanks.

Syntax

\[
\text{result} = \text{ADJUSTL} (\text{string})
\]

\( \text{string} \) (Input) Must be of type character.
Results
The result type is character with the same length and kind parameter as string. The value of the result is the same as string, except that any leading blanks have been removed and inserted as trailing blanks.

Example

```fortran
CHARACTER(16) STRING
STRING= ADJUSTL(' Fortran 90 ') ! returns 'Fortran 90 '
ADJUSTL (' SUMMERTIME') ! has the value 'SUMMERTIME '
```

See Also
- A to B
- ADJUSTR

ADJUSTR

**Elemental Intrinsic Function (Generic):** Adjusts a character string to the right, removing trailing blanks and inserting leading blanks.

Syntax

```
result = ADJUSTR (string)
```

string (Input) Must be of type character.

Results

The result type is character with the same length and kind parameter as string.

The value of the result is the same as string, except that any trailing blanks have been removed and inserted as leading blanks.

Example

```fortran
CHARACTER(16) STRING
STRING= ADJUSTL(' Fortran 90 ') ! returns ' Fortran 90'
ADJUSTL (' SUMMERTIME ')! has the value ' SUMMERTIME '
```

See Also
- A to B
- ADJUSTL
AIMAG

Elemental Intrinsic Function (Generic):
Returns the imaginary part of a complex number.
This function can also be specified as IMAG.

Syntax

result = AIMAG (z)

z (Input) Must be of type complex.

Results
The result type is real with the same kind parameter as z. If z has the value (x, y), the result has the value y.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIMAG (^1)</td>
<td>COMPLEX(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DIMAG</td>
<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QIMAG</td>
<td>COMPLEX(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\) The setting of compiler options specifying real size can affect AIMAG.

To return the real part of complex numbers, use REAL.

Example
AIMAG ((4.0, 5.0)) has the value 5.0.
The program AIMAG.F90 applies the quadratic formula to a polynomial and allows for complex results:

```fortran
REAL a, b, c
COMPLEX ans1, ans2, d
WRITE ( *, 100)
100 FORMAT (' Enter A, b, and c of the ', &
   'polynomial ax**2 + bx + c: ')
READ (*, *) a, b, c
d = CSQRT (CMPLX (b**2 - 4.0*a*c)) ! d is either:
   ! 0.0 + i root, or
   ! root + i 0.0
ans1 = (-b + d) / (2.0 * a)
ans2 = (-b + d) / (2.0 * a)
WRITE (*, 200)
200 FORMAT (/ ' The roots are:' /)
WRITE (*, 300) REAL(ans1), AIMAG(ans1), &
   REAL(ans2), AIMAG(ans2)
300 FORMAT (' X = ', F10.5, ' + i', F10.5)
END

See Also
• A to B
• CONJG
• DBLE

AINT

Elemental Intrinsic Function (Generic):
Truncates a value to a whole number.

Syntax
result = AINT (a [,kind])
```
a
(Input) Must be of type real.

kind
(Input; optional) Must be a scalar integer initialization expression.

Results
The result type is real. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter is that of a.

The result is defined as the largest integer whose magnitude does not exceed the magnitude of a and whose sign is the same as that of a. If |a| is less than 1, AINT(a) has the value zero.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>AINT</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DINT</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QINT</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

To round rather than truncate, use ANINT.

Example
AINT (3.678) has the value 3.0.
AINT (-1.375) has the value -1.0.
REAL r1, r2
REAL(8) r3(2)
r1 = AINT(2.6)  ! returns the value 2.0
r2 = AINT(-2.6) ! returns the value -2.0
r3 = AINT((/1.3, 1.9/), KIND = 8)  ! returns the values
       (1.0D0, 1.0D0)

See Also
• A to B
• ANINT
ALARM

**Portability Function:** Causes a subroutine to begin execution after a specified amount of time has elapsed.

**Module**

USE IFPORT

**Syntax**

```fortran
result = ALARM (time, proc)
```

- **time**  (Input) Integer. Specifies the time delay, in seconds, between the call to ALARM and the time when `proc` is to begin execution. If `time` is 0, the alarm is turned off and no routine is called.

- **proc**  (Input) Name of the procedure to call. The procedure takes no arguments and must be declared EXTERNAL.

**Results**

The return value is INTEGER(4). It is zero if no alarm is pending. If an alarm is pending (has already been set by a previous call to ALARM), it returns the number of seconds remaining until the previously set alarm is to go off, rounded up to the nearest second.

After ALARM is called and the timer starts, the calling program continues for `time` seconds. The calling program then suspends and calls `proc`, which runs in another thread. When `proc` finishes, the alarm thread terminates, the original thread resumes, and the calling program resets the alarm. Once the alarm goes off, it is disabled until set again.

If `proc` performs I/O or otherwise uses the Fortran library, you need to compile it with one of the multithread libraries.

The thread that `proc` runs in has a higher priority than any other thread in the process. All other threads are essentially suspended until `proc` terminates, or is blocked on some other event, such as I/O.

No alarms can occur after the main process ends. If the main program finishes or any thread executes an EXIT call, than any pending alarm is deactivated before it has a chance to run.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

INTEGER(4) numsec, istat
EXTERNAL subprog

numsec = 4
write *, "subprog will begin in ", numsec, " seconds"

ISTAT = ALARM (numsec, subprog)

See Also
- A to B

ALIAS Directive

*General Compiler Directive: Declares alternate external names for external subprograms.*

Syntax

c
DEC$ ALIAS internal-name, external-name

<table>
<thead>
<tr>
<th>c</th>
<th>internal-name</th>
<th>external-name</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>The name of the subprogram as used in the current program unit.</td>
<td>A name or a character constant, delimited by apostrophes or quotation marks.</td>
</tr>
<tr>
<td>internal-name</td>
<td>Is a c, C, !, or *. (See Syntax Rules for Compiler Directives.)</td>
<td></td>
</tr>
<tr>
<td>external-name</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Description

If a name is specified, the name (in uppercase) is used as the external name for the specified internal-name. If a character constant is specified, it is used as is; the string is not changed to uppercase, nor are blanks removed.

The ALIAS directive affects only the external name used for references to the specified internal-name.

Names that are not acceptable to the linker will cause link-time errors.

See Also
- A to B
• ATTRIBUTES- ALIAS option
• General Compiler Directives

**ALL**

Transformational Intrinsic Function (Generic):
Determines if all values are true in an entire array or in a specified dimension of an array.

**Syntax**

```
result = ALL (mask [,dim])
```

- `mask` (Input) Must be a logical array.
- `dim` (Input; optional) Must be a scalar integer with a value in the range 1 to n, where n is the rank of `mask`.

**Results**

The result is an array or a scalar of type logical.

The result is a scalar if `dim` is omitted or `mask` has rank one. A scalar result is true only if all elements of `mask` are true, or `mask` has size zero. The result has the value false if any element of `mask` is false.

An array result has the same type and kind parameters as `mask`, and a rank that is one less than `mask`. Its shape is \((d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n)\), where \((d_1, d_2, ..., d_n)\) is the shape of `mask`.

Each element in an array result is true only if all elements in the one dimensional array defined by `mask(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)` are true.
Example

LOGICAL mask( 2, 3), AR1(3), AR2(2)

mask = RESHAPE((/ .TRUE., .TRUE., .FALSE., .TRUE., .FALSE., &
                 .FALSE./), (/2,3/))

! mask is true false false
! true true false

AR1 = ALL(mask, DIM = 1) ! evaluates the elements column by
! column yielding [true false false]

AR2 = ALL(mask, DIM = 2) ! evaluates the elements row by row
! yielding [false false].

ALL ((/ .TRUE., .FALSE., .TRUE./)) has the value false because some elements of MASK are not
true.

ALL ((/ .TRUE., .TRUE., .TRUE./)) has the value true because all elements of MASK are true.

A is the array

    [ 1 5 7 ]
    [ 3 6 8 ]

and B is the array

    [ 0 5 7 ]
    [ 2 6 9 ].

ALL (A .EQ. B, DIM=1) tests to see if all elements in each column of A are equal to the elements
in the corresponding column of B. The result has the value (false, true, false) because only the
second column has elements that are all equal.

ALL (A .EQ. B, DIM=2) tests to see if all elements in each row of A are equal to the elements
in the corresponding row of B. The result has the value (false, false) because each row has
some elements that are not equal.

- COUNT
**ALLOCATABLE**

*Statement and Attribute:* Specifies that an array is an allocatable array with a deferred shape. The shape of an allocatable array is determined when an ALLOCATE statement is executed, dynamically allocating space for the array.

**Syntax**

The ALLOCATABLE attribute can be specified in a type declaration statement or an ALLOCATABLE statement, and takes one of the following forms:

**Type Declaration Statement:**

```plaintext
type, [att-ls,] ALLOCATABLE [att-ls,] :: a[(d-spec)] [, a[(d-spec)]] ...
```

**Statement:**

```plaintext
ALLOCATABLE [::] a[(d-spec)] [, a[(d-spec)]] ...
```

- *type* is a data type specifier.
- *att-ls* is an optional list of attribute specifiers.
- *a* is the name of the allocatable array.
- *d-spec* is a deferred-shape specification (: [:] ...). Each colon represents a dimension of the array.

**Description**

If the array is given the DIMENSION attribute elsewhere in the program, it must be declared as a deferred-shape array.

When the allocatable array is no longer needed, it can be deallocated by execution of a DEALLOCATE statement.

An allocatable array cannot be specified in a COMMON, EQUIVALENCE, DATA, or NAMELIST statement.

Allocatable arrays are not saved by default. If you want to retain the values of an allocatable array across procedure calls, you must specify the SAVE attribute for the array.
Example

!Method for creating and allocating deferred-shape arrays.
INTEGER, ALLOCATABLE :: matrix(:, :)
REAL, ALLOCATABLE :: vector(:)
...
ALLOCATE(matrix(3, 5), vector(-2:N+2))
...
The following example shows a type declaration statement specifying the ALLOCATABLE attribute:
REAL, ALLOCATABLE :: Z(:, :, :)
The following is an example of the ALLOCATABLE statement:
REAL A, B(:)
ALLOCATABLE :: A(:, :), B

See Also

- Compatible attributes
- DEALLOCATE
- Arrays
- Allocation of Allocatable Arrays
- SAVE

ALLOCATE

Statement: Dynamically creates storage for allocatable arrays and pointer targets. The storage space allocated is uninitialized.

Syntax
ALLOCATE (object[(s-spec)] [, object[(s-spec[, s-spec]...)] ]...[, alloc-opt])

object 
Is the object to be allocated. It is a variable name or structure component, and must be a pointer or allocatable array. The object can be of type character with zero length.
Is a shape specification in the form [lower-bound:]upper-bound. Each bound must be a scalar integer expression. The number of shape specifications must be the same as the rank of the object.

(Output) Is one of the following:

- STAT=sv  
  sv is a scalar integer variable in which the status of the allocation is stored.

- ERRMSG=ev  
  ev is a scalar default character value in which an error condition is stored if such a condition occurs.

Description

A bound in s-spec must not be an expression containing an array inquiry function whose argument is any allocatable object in the same ALLOCATE statement; for example, the following is not permitted:

```fortran
INTEGER ERR
INTEGER, ALLOCATABLE :: A(:), B(:)
...
ALLOCATE(A(10:25), B(SIZE(A)), STAT=ERR) ! A is invalid as an argument
  ! to function SIZE
```

If a STAT variable or ERRMSG variable is specified, it must not be allocated in the ALLOCATE statement in which it appears. If the allocation is successful, the variable is set to zero. If the allocation is not successful, an error condition occurs, and the variable is set to a positive integer value (representing the run-time error); the ERRMSG variable contains the error condition. If no STAT variable is specified and an error condition occurs, program execution terminates.

To release the storage for an allocated array, use DEALLOCATE.

To determine whether an allocatable array is currently allocated, use the AlLOCATED intrinsic function.

To determine whether a pointer is currently associated with a target, use the ASSOCIATED intrinsic function.
Example

! Method for creating and allocating deferred shape arrays.
INTEGER, ALLOCATABLE:: matrix(:,:)
REAL, ALLOCATABLE:: vector(:)

ALLOCATE (matrix(3,5), vector(-2:N+2))

The following shows another example of the ALLOCATE statement:

INTEGER J, N, ALLOC_ERR
REAL, ALLOCATABLE :: A(:), B(:,:)

ALLOCATE(A(0:80), B(-3:J+1, N), STAT = ALLOC_ERR)

See Also
• A to B
• ALLOCATABLE
• ALLOCATED
• DEALLOCATE
• ASSOCIATED
• POINTER
• Dynamic Allocation
• Pointer Assignments

ALLOCATED

Inquiry Intrinsic Function (Generic): Indicates whether an allocatable array is currently allocated.

Syntax

result = ALLOCATED (array)

array (Input) Must be an allocatable array.
**Results**

The result is a scalar of type default logical.

The result has the value true if *array* is currently allocated, false if *array* is not currently allocated, or undefined if its allocation status is undefined.

**Example**

```fortran
REAL, ALLOCATABLE :: A(:)

...
IF (.NOT. ALLOCATED(A)) ALLOCATE (A (5))
```

Consider the following:

```fortran
REAL, ALLOCATABLE, DIMENSION (:,:,:) :: E
PRINT *, ALLOCATED (E)   ! Returns the value false
ALLOCATE (E (12, 15, 20))
PRINT *, ALLOCATED (E)   ! Returns the value true
```

**See Also**

- A to B
- ALLOCATABLE
- ALLOCATE
- DEALLOCATE
- Arrays
- Dynamic Allocation
**AND**

*Elemental Intrinsic Function (Generic)*

**Example**

```fortran
INTEGER(1) i, m
INTEGER result
INTEGER(2) result2
i = 1
m = 3
result = AND(i,m) ! returns an integer of default type
    ! (INTEGER(4) unless reset by user) whose
    ! value = 1
result2 = AND(i,m) ! returns an INTEGER(2) with value = 1
```

**See Also**

- A to B
- IAND

**ANINT**

*Elemental Intrinsic Function (Generic): Calculates the nearest whole number.*

**Syntax**

```fortran
result = ANINT (a[,kind] )
```

- `a` (Input) Must be of type real.
- `kind` (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is real. If `kind` is present, the kind parameter is that specified by `kind`; otherwise, the kind parameter is that of `a`. If `a` is greater than zero, `ANINT (a)` has the value `AINT (a + 0.5)`; if `a` is less than or equal to zero, `ANINT (a)` has the value `AINT (a - 0.5)`.
To truncate rather than round, use \texttt{AINT}.

\textbf{Example}

\texttt{ANINT (3.456)} has the value 3.0.
\texttt{ANINT (-2.798)} has the value -3.0.

Consider the following:

\begin{verbatim}
REAL r1, r2
r1 = ANINT(2.6)  ! returns the value 3.0
r2 = ANINT(-2.6) ! returns the value -3.0
\end{verbatim}

\texttt{! ANINT.F90 Calculates and adds tax to a purchase amount.}

\begin{verbatim}
REAL amount, taxrate, tax, total
taxrate = 0.081
amount = 12.99
tax = ANINT (amount * taxrate * 100.0) / 100.0
total = amount + tax
WRITE (*, 100) amount, tax, total
100 FORMAT ( 1X, 'AMOUNT', F7.2 /
+ 1X, 'TAX ', F7.2 /
+ 1X, 'TOTAL ', F7.2)
\end{verbatim}

\texttt{END}

\textbf{See Also}

- A to B
- NINT
ANY

Transformational Intrinsic Function (Generic):
Determines if any value is true in an entire array
or in a specified dimension of an array.

Syntax

result = ANY (mask [, dim])

mask            (Input) Must be a logical array.
dim             (Input; optional) Must be a scalar integer expression with a value
                  in the range 1 to n, where n is the rank of mask.

Results

The result is an array or a scalar of type logical.
The result is a scalar if dim is omitted or mask has rank one. A scalar result is true if any elements
of mask are true. The result has the value false if no element of mask is true, or mask has size zero.

An array result has the same type and kind parameters as mask, and a rank that is one less
than mask. Its shape is (d₁, d₂, ..., dᵣ₋₁, dᵣ₊₁, ..., dₙ), where (d₁, d₂, ..., dₙ) is the shape
of mask.

Each element in an array result is true if any elements in the one dimensional array defined by
mask(s₁, s₂, ..., sᵣ₋₁, :, sᵣ₊₁, ..., sₙ) are true.

Example

LOGICAL mask( 2, 3), AR1(3), AR2(2)
logical, parameter :: T = .true.
logical, parameter :: F = .false.
DATA mask /T, T, F, T, F, F/

! mask is   true false false
! true true false

AR1 = ANY(mask,DIM = 1)  ! evaluates the elements column by
! column yielding [true true false]

AR2 = ANY(mask,DIM = 2)  ! evaluates the elements row by row
! yielding [true true]
ANY ((/FALSE., FALSE., TRUE./)) has the value true because one element is true.

A is the array

\[
\begin{bmatrix}
1 & 5 & 7 \\
3 & 6 & 8
\end{bmatrix}
\]

and B is the array

\[
\begin{bmatrix}
0 & 5 & 7 \\
2 & 6 & 9
\end{bmatrix}
\]

ANY (A EQ B, DIM=1) tests to see if any elements in each column of A are equal to the elements in the corresponding column of B. The result has the value (false, true, true) because the second and third columns have at least one element that is equal.

ANY (A EQ B, DIM=2) tests to see if any elements in each row of A are equal to the elements in the corresponding row of B. The result has the value (true, true) because each row has at least one element that is equal.

See Also
• A to B
• ALL
• COUNT

APPENDMENUQQ (W*32, W*64)

QuickWin Function: Appends a menu item to the end of a menu and registers its callback subroutine.

Module
USE IFQWIN

Syntax
result = APPENDMENUQQ (menuID, flags, text, routine)

menuID (Input) INTEGER(4). Identifies the menu to which the item is appended, starting with 1 as the leftmost menu.

flags (Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see the Results section below). The following constants are available:

• $MENUGRAYED - Disables and grays out the menu item.
• `$MENUDISABLED` - Disables but does not gray out the menu item.
• `$MENUENABLED` - Enables the menu item.
• `$MENUSEPARATOR` - Draws a separator bar.
• `$MENUCHECKED` - Puts a check by the menu item.
• `$MENUUNCHECKED` - Removes the check by the menu item.

**text**

(Input) Character*(*). Menu item name. Must be a null-terminated C string, for example, 'WORDS OF TEXT'C.

**routine**

(Input) EXTERNAL. Callback subroutine that is called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:

• WINPRINT - Prints the program.
• WINSAVE - Saves the program.
• WINEXIT - Terminates the program.
• WINSELECTTEXT - Selects text from the current window.
• WINSELECTGRAPHICS - Selects graphics from the current window.
• WINSELECTALL - Selects the entire contents of the current window.
• WININPUT - Brings to the top the child window requesting input and makes it the current window.
• WINCOPY - Copies the selected text and/or graphics from the current window to the Clipboard.
• WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
• WINCLEARPASTE - Clears the paste buffer.
• WINSIZETOFIT - Sizes output to fit window.
• WINFULLSCREEN - Displays output in full screen.
• WINSTATE - Toggles between pause and resume states of text output.
• WINCASCADE - Cascades active windows.
• WINTILE - Tiles active windows.
• WINARRANGE - Arranges icons.
• WINSTATUS - Enables a status bar.
• WININDEX - Displays the index for QuickWin help.
• WINUSING - Displays information on how to use Help.
• WINABOUT - Displays information about the current QuickWin application.
• NUL - No callback routine.

Results

The result type is logical. It is .TRUE. if successful; otherwise, .FALSE..

You do not need to specify a menu item number, because APPENDMENUSQQ always adds the new item to the bottom of the menu list. If there is no item yet for a menu, your appended item is treated as the top-level menu item (shown on the menu bar), and text becomes the menu title. APPENDMENUSQQ ignores the callback routine for a top-level menu item if there are any other menu items in the menu. In this case, you can set routine to NUL.

If you want to insert a menu item into a menu rather than append to the bottom of the menu list, use INSERTMENUSQQ.

The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUCHECKED .OR. $MENUBUFFERED. Some combinations do not make sense, such as $MENUBUFFERED and $MENUDISABLED, and lead to undefined behavior.

You can create quick-access keys in the text strings you pass to APPENDMENUSQQ as text by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, text should be "P&rint". Quick-access keys allow users of your program to activate that menu item with the key combination ALT+QUICK-ACCESS-KEY (ALT+R in the example) as an alternative to selecting the item with the mouse.

For more information about customizing QuickWin menus, see Building Applications: Using QuickWin Overview.

Compatibility

QUICKWIN GRAPHICS LIB
Example

USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str

...!

! Append two items to the bottom of the first (FILE) menu
str = '&Add to File Menu'C ! 'A' is a quick-access key
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
str = 'Menu Item &2b'C ! '2' is a quick-access key
result = APPENDMENUQQ(1, $MENUENABLED, str, WINCASCADE)

! Append an item to the bottom of the second (EDIT) menu
str = 'Add to Second &Menu'C ! 'M' is a quick-access key
result = APPENDMENUQQ(2, $MENUENABLED, str, WINTILE)

• MODIFYMENUROUTINEQQ
• MODIFYMENUSTRINGQQ

ARC, ARC_W (W*32, W*64)

Graphics Functions: Draw elliptical arcs using the current graphics color.

Module
USE IFQWIN

Syntax
result = ARC (x1, y1, x2, y2, x3, y3, x4, y4)
result = ARC_W (wx1, wy1, wx2, wy2, wx3, wy3, wx4, wy4)
$x1, y1$ (Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

$x2, y2$ (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

$x3, y3$ (Input) INTEGER(2). Viewport coordinates of start vector.

$x4, y4$ (Input) INTEGER(2). Viewport coordinates of end vector.

$wx1, wy1$ (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

$wx2, wy2$ (Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

$wx3, wy3$ (Input) REAL(8). Window coordinates of start vector.

$wx4, wy4$ (Input) REAL(8). Window coordinates of end vector.

**Results**

The result type is INTEGER(2). It is nonzero if successful; otherwise, 0. If the arc is clipped or partially out of bounds, the arc is considered successfully drawn and the return is 1. If the arc is drawn completely out of bounds, the return is 0.

The center of the arc is the center of the bounding rectangle defined by the points $(x1, y1)$ and $(x2, y2)$ for ARC and $(wx1, wy1)$ and $(wx2, wy2)$ for ARC_W.

The arc starts where it intersects an imaginary line extending from the center of the arc through $(x3, y3)$ for ARC and $(wx3, wy3)$ for ARC_W. It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through $(x4, y4)$ for ARC and $(wx4, wy4)$ for ARC_W.

ARC uses the view-coordinate system. ARC_W uses the window-coordinate system. In each case, the arc is drawn using the current color.

**NOTE.** The ARC routine described here is a QuickWin graphics routine. If you are trying to use the Microsoft* Platform SDK version of the Arc routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Arc.
Example

This program draws the arc shown below.

```fortran
USE IFQWIN

INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4
x1 = 80; y1 = 50
x2 = 240; y2 = 150
x3 = 120; y3 = 75
x4 = 90; y4 = 180
status = ARC( x1, y1, x2, y2, x3, y3, x4, y4 )
END
```

ASIN

Elemental Intrinsic Function (Generic):

Produces the arcsine of \( x \).

Syntax

```
result = ASIN( x )
```

\( x \)  
(Input) Must be of type real. The \(| x |\) must be less than or equal to 1.

Results

The result type is the same as \( x \) and is expressed in radians. The value lies in the range \(-\pi/2\) to \( \pi/2 \).
### Example

ASIN (0.79345021) has the value 0.9164571.

### ASIND

**Elemental Intrinsic Function (Generic):**

*Produces the arcsine of $x$.*

**Syntax**

\[
\text{result} = \text{ASIND} (x)
\]

$x$  
(Input) Must be of type real. The $|x|$ must be less than or equal to 1.

**Results**

The result type is the same as $x$ and is expressed in degrees. The value lies in the range $-90$ to $90$ degrees.

<table>
<thead>

<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ASIND (0.2467590) has the value 14.28581.
**ASINH**

*Elemental Intrinsic Function (Generic):*  
Produces the hyperbolic arcsine of \( x \).

**Syntax**

\[
\text{result} = \text{ASINH}(x)
\]

\( x \)  
(Input) Must be of type real.

**Results**

The result type is the same as \( x \).

<table>

<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ASINH (1.0) has the value -0.88137.

ASINH (180.0) has the value 5.88611.

**ASSIGN - Label Assignment**

*Statement:* Assigns a statement label value to an integer variable. This feature has been deleted in Fortran 95; it was obsolescent in Fortran 90. *Intel® Fortran* fully supports features deleted in Fortran 95.

**Syntax**

\[
\text{ASSIGN label TO var}
\]

\( label \)  
Is the label of a branch target or FORMAT statement in the same scoping unit as the ASSIGN statement.

\( var \)  
Is a scalar integer variable.
When an ASSIGN statement is executed, the statement label is assigned to the integer variable. The variable is then undefined as an integer variable and can only be used as a label (unless it is later redefined with an integer value).

The ASSIGN statement must be executed before the statements in which the assigned variable is used.

Indirect branching through integer variables makes program flow difficult to read, especially if the integer variable is also used in arithmetic operations. Using these statements permits inconsistent usage of the integer variable, and can be an obscure source of error. The ASSIGN statement was used to simulate internal procedures, which now can be coded directly.

**Example**

The value of a label is not the same as its number; instead, the label is identified by a number assigned by the compiler. In the following example, 400 is the label number (not the value) of IVBL:

```
ASSIGN 400 TO IVBL
```

Variables used in ASSIGN statements are not defined as integers. If you want to use a variable defined by an ASSIGN statement in an arithmetic expression, you must first define the variable by a computational assignment statement or by a READ statement, as in the following example:

```
IVBL = 400
```

The following example shows ASSIGN statements:

```
INTEGER ERROR
...
ASSIGN 10 TO NSTART
ASSIGN 99999 TO KSTOP
ASSIGN 250 TO ERROR
```

Note that NSTART and KSTOP are integer variables implicitly, but ERROR must be previously declared as an integer variable.

The following statement associates the variable NUMBER with the statement label 100:

```
ASSIGN 100 TO NUMBER
```

If an arithmetic operation is subsequently performed on variable NUMBER (such as follows), the run-time behavior is unpredictable:

```
NUMBER = NUMBER + 1
```
To return NUMBER to the status of an integer variable, you can use the following statement:

\[ \text{NUMBER} = 10 \]

This statement dissociates NUMBER from statement 100 and assigns it an integer value of 10. Once NUMBER is returned to its integer variable status, it can no longer be used in an assigned GO TO statement.

- A to B
- Assignment: intrinsic
- Obsolescent Features in Fortran 90

**Assignment(=) - Defined Assignment**

**Statement:** An interface block that defines generic assignment. The only procedures allowed in the interface block are subroutines that can be referenced as defined assignments.

**Syntax**

The initial line for such an interface block takes the following form:

\[ \text{INTERFACE ASSIGNMENT (=} \]

**Description**

The subroutines within the interface block must have two nonoptional arguments, the first with intent OUT or INOUT, and the second with intent IN.

A defined assignment is treated as a reference to a subroutine. The left side of the assignment corresponds to the first dummy argument of the subroutine; the right side of the assignment corresponds to the second argument.

The ASSIGNMENT keyword extends or redefines an assignment operation if both sides of the equal sign are of the same derived type.

Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE statement.

Any procedure reference involving generic assignment must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.
Example

The following is an example of a procedure interface block defining assignment:

```
INTERFACE ASSIGNMENT (=)
    SUBROUTINE BIT_TO_NUMERIC (NUM, BIT)
        INTEGER, INTENT(OUT) :: NUM
        LOGICAL, INTENT(IN) :: BIT(:)
    END SUBROUTINE BIT_TO_NUMERIC
    SUBROUTINE CHAR_TO_STRING (STR, CHAR)
        USE STRING_MODULE ! Contains definition of type STRING
        TYPE(STRING), INTENT(OUT) :: STR ! A variable-length string
        CHARACTER(*) , INTENT(IN) :: CHAR
    END SUBROUTINE CHAR_TO_STRING
END INTERFACE
```

The following example shows two equivalent ways to reference subroutine BIT_TO_NUMERIC:

```
CALL BIT_TO_NUMERIC(X, (NUM(I:J)))
X = NUM(I:J)
```
The following example shows two equivalent ways to reference subroutine CHAR_TO_STRING:

```fortran
CALL CHAR_TO_STRING(CH, '432C')
CH = '432C'
```

! Converting circle data to interval data.

```fortran
module mod1

TYPE CIRCLE
    REAL radius, center_point(2)
END TYPE CIRCLE

TYPE INTERVAL
    REAL lower_bound, upper_bound
END TYPE INTERVAL

CONTAINS

SUBROUTINE circle_to_interval(I,C)
    type (interval), INTENT(OUT)::I
    type (circle), INTENT(IN)::C

! Project circle center onto the x=-axis
! Note: the length of the interval is the diameter of the circle

    I%lower_bound = C%center_point(1) - C%radius
    I%upper_bound = C%center_point(1) + C%radius

END SUBROUTINE circle_to_interval

end module mod1

PROGRAM assign
    use mod1

    TYPE(CIRCLE) circle1
    TYPE(INTERVAL) interval1

    INTERFACE ASSIGNMENT(=)
        module procedure circle_to_interval
    END INTERFACE

    ! Begin executable part of program
```
circle1%radius = 2.5
circle1%center_point = (/3.0,5.0/)
interval1 = circle1

... 
END PROGRAM

• INTERFACE
• Assignment Statements

Assignment - Intrinsic Computational

**Statement:** Assigns a value to a nonpointer variable. In the case of pointers, intrinsic assignment is used to assign a value to the target associated with the pointer variable. The value assigned to the variable (or target) is determined by evaluation of the expression to the right of the equal sign.

**Syntax**

```
variable = expression
```

*variable* Is the name of a scalar or array of intrinsic or derived type (with no defined assignment). The array cannot be an assumed-size array, and neither the scalar nor the array can be declared with the PARAMETER or INTENT(IN) attribute.

*expression* Is of intrinsic type or the same derived type as *variable*. Its shape must conform with *variable*. If necessary, it is converted to the same type and kind as *variable*.

**Description**

Before a value is assigned to the variable, the expression part of the assignment statement and any expressions within the variable are evaluated. No definition of expressions in the variable can affect or be affected by the evaluation of the expression part of the assignment statement.
NOTE. When the run-time system assigns a value to a scalar integer or character variable and the variable is shorter than the value being assigned, the assigned value may be truncated and significant bits (or characters) lost. This truncation can occur without warning, and can cause the run-time system to pass incorrect information back to the program.

If the variable is a pointer, it must be associated with a definable target. The shape of the target and expression must conform and their type and kind parameters must match.

If the _DEC$ NOSTRICT compiler directive (the default) is in effect, then you can assign a character expression to a noncharacter variable, and a noncharacter variable or array element (but not an expression) to a character variable.
Example

REAL a, b, c
LOGICAL abigger
CHARACTER(16) assertion
c = .01
a = SQRT (c)
b = c**2
assertion = 'a > b'
abigger = (a .GT. b)
WRITE (*, 100) a, b
100 FORMAT (' a =', F7.4, ' b =', F7.4)
IF (abigger) THEN
    WRITE (*, *) assertion, ' is true.'
ELSE
    WRITE (*, *) assertion, ' is false.'
END IF
END

! The program above has the following output:
! a = .1000  b = .0001  a > b is true.
! The following code shows legal and illegal
! assignment statements:
!
! INTEGER i, j
REAL rone(4), rtwo(4), x, y
COMPLEX z
CHARACTER name6(6), name8(8)
i = 4
x = 2.0
z = (3.0, 4.0)
rone(1) = 4.0
rone(2) = 3.0
rone(3) = 2.0
rone(4) = 1.0
name8 = 'Hello,'

! The following assignment statements are legal:
i = rone(2); j = rone(i); j = x
y = x; y = z; y = rone(3); rtwo = rone; rtwo = 4.7
name6 = name8

! The following assignment statements are illegal:
name6 = x + 1.0; int = name8//'test'; y = rone

END

See Also
• A to B
• Assignment: defined
• NOSTRICT directive

ASSOCIATED

Inquiry Intrinsic Function (Generic): Returns the association status of its pointer argument or indicates whether the pointer is associated with the target.

Syntax

result = ASSOCIATED (pointer [, target])

| pointer | (Input) Must be a pointer. It can be of any data type. The pointer association status must be defined. |
| target  | (Input; optional) Must be a pointer or target. If it is a pointer, the pointer association status must be defined. |
Results
The result is a scalar of type default logical. The setting of compiler options specifying integer size can affect this function.

If only \texttt{pointer} appears, the result is true if it is currently associated with a target; otherwise, the result is false.

If \texttt{target} also appears and is a target, the result is true if \texttt{pointer} is currently associated with \texttt{target}; otherwise, the result is false.

If \texttt{target} is a pointer, the result is true if both \texttt{pointer} and \texttt{target} are currently associated with the same target; otherwise, the result is false. (If either \texttt{pointer} or \texttt{target} is disassociated, the result is false.)

Example

REAL C (:), D(:), E(5)
POINTER C, D
TARGET E
LOGICAL STATUS

\begin{verbatim}
C => E ! pointer assignment
D => E ! pointer assignment
STATUS = ASSOCIATED(C) ! returns TRUE; C is associated
STATUS = ASSOCIATED(C, E) ! returns TRUE; C is associated with E
STATUS = ASSOCIATED (C, D) ! returns TRUE; C and D are associated
! with the same target
\end{verbatim}

Consider the following:

\begin{verbatim}
REAL, TARGET, DIMENSION (0:50) :: TAR
REAL, POINTER, DIMENSION (:) :: PTR
PTR => TAR
PRINT *, ASSOCIATED (PTR, TAR) ! Returns the value true
\end{verbatim}
The subscript range for PTR is 0:50. Consider the following pointer assignment statements:

1. PTR => TAR (:) 
2. PTR => TAR (0:50) 
3. PTR => TAR (0:49) 

For statements 1 and 2, ASSOCIATED (PTR, TAR) is true because TAR has not changed (the subscript range for PTR in both cases is 1:51, following the rules for deferred-shape arrays). For statement 3, ASSOCIATED (PTR, TAR) is false because the upper bound of TAR has changed.

Consider the following:

```fortran
REAL, POINTER, DIMENSION (:) :: PTR2, PTR3
ALLOCATE (PTR2 (0:15))
PTR3 => PTR2
PRINT *, ASSOCIATED (PTR2, PTR3)  ! Returns the value true
...
NULLIFY (PTR2)
NULLIFY (PTR3)
PRINT *, ASSOCIATED (PTR2, PTR3)  ! Returns the value false
```

ASSUME_ALIGNED

*General Compiler Directive: Specifies that an entity in memory is aligned.*

**Syntax**

```fortran
cDEC$ ASSUME_ALIGNED address1:n1 [, address2:n2]... 
```

- `c`  
  - Is a c, C, !, or *. (See Syntax Rules for Compiler Directives.)
address  
A memory reference. It can be of any data type, kind, or rank. It cannot be any of the following:

- An entity in COMMON (or an entity EQUIVALENCEd to something in COMMON)
- A component of a variable of derived type or a record field reference
- An entity accessed by use or host association

n  
A positive integer initialization expression. Its value must be a power of 2 between 1 and 256, that is, 1, 2, 4, 8, 16, 32, 64, 128, 256.

If you specify more than one address item, they must be separated by a comma.

If address is a Cray POINTER or it has the POINTER attribute, it is the POINTER and not the pointee or the TARGET that is assumed aligned.

If you specify an invalid value for n, an error message is displayed.

See Also
- A to B
- PREFETCH
- ATTRIBUTES ALIGN

ASYNCHRONOUS

Statement and Attribute: Specifies that a variable can be used for asynchronous input and output.

Syntax
The ASYNCHRONOUS attribute can be specified in a type declaration statement or an ASYNCHRONOUS statement, and takes one of the following forms:

Type Declaration Statement:

\[ \text{type}, [\text{att-ls,}] \ \text{ASYNCHRONOUS} \ [\text{att-ls,}] \ :: \ \text{var},[, \text{var}] \ ... \]

Statement:

\[ \text{ASYNCHRONOUS} \ :: [\text{var},[,, \text{var}] \ ... \]

\[ \text{type} \quad \text{Is a data type specifier.} \]
att-\text{-}ls \quad \text{Is an optional list of attribute specifiers.}

\text{var} \quad \text{Is the name of a variable.}

\section*{Description}

Asynchronous I/O, or non-blocking I/O, allows a program to continue processing data while the I/O operation is performed in the background.

A variable can have the ASYNCHRONOUS attribute in a particular scoping unit without necessarily having it in other scoping units. If an object has the ASYNCHRONOUS attribute, then all of its subobjects also have the ASYNCHRONOUS attribute.

The ASYNCHRONOUS attribute can also be implied by use of a variable in an asynchronous READ or WRITE statement.

\section*{Examples}

The following example shows how the ASYNCHRONOUS attribute can be applied in an OPEN and READ statement.

\begin{verbatim}
program test
integer, asynchronous, dimension(100) :: array
open (unit=1, file='asynch.dat', asynchronous='YES', &
   form='unformatted')
write (1) (i,i=1,100)
rewind (1)
read (1, asynchronous='YES') array
wait(1)
write (*,*) array(1:10)
end
\end{verbatim}

\section*{See Also}

### ATAN

**Elemental Intrinsic Function (Generic):**

Produces the arctangent of \( x \).

**Syntax**

\[
\text{result} = \text{ATAN} \ (x)
\]

\( x \)  
(Input) Must be of type real.

**Results**

The result type is the same as \( x \) and is expressed in radians. The value lies in the range -\( \pi/2 \) to \( \pi/2 \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAN</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DATAN</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAN</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ATAN (1.5874993) has the value 1.008666.

### ATAN2

**Elemental Intrinsic Function (Generic):**

Produces an arctangent (inverse tangent). The result is the principal value of the argument of the nonzero complex number \((x, y)\).

**Syntax**

\[
\text{result} = \text{ATAN2} \ (y, x)
\]

\( y \)  
(Input) Must be of type real.

\( x \)  
(Input) Must have the same type and kind parameters as \( y \). If \( y \) has the value zero, \( x \) cannot have the value zero.
Results

The result type is the same as \( x \) and is expressed in radians. The value lies in the range \(-\pi \leq \text{ATAN2} (y, x) \leq \pi\).

If \( x \) is not zero, the result is approximately equal to the value of \( \arctan \left( \frac{y}{x} \right) \).

If \( y > 0 \), the result is positive.

If \( y < 0 \), the result is negative.

If \( y \) is zero and \( x > 0 \), the result is \( y \) (so for \( x > 0 \), \( \text{ATAN2} ((+0.0), x) = +0.0 \) and \( \text{ATAN2} ((-0.0), x) = -0.0 \)).

If \( y \) is a positive real zero and \( x < 0 \), the result is \( \pi \).

If \( y \) is a negative real zero and \( x < 0 \), the result is \(-\pi\).

If \( x \) is a positive real zero, the result is \( \pi/2 \).

If \( y \) is a negative real zero, the result is \(-\pi/2\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAN2</td>
<td>REAL(4)</td>
<td>REAL(4)</td>

<tr>
<td>DATAN2</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAN2</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

\( \text{ATAN2} (2.679676, 1.0) \) has the value 1.213623.

If \( Y \) is an array that has the value

\[
\begin{bmatrix}
  1 & 1 \\
  -1 & -1 \\
\end{bmatrix}
\]

and \( X \) is an array that has the value

\[
\begin{bmatrix}
  -1 & 1 \\
  -1 & 1 \\
\end{bmatrix},
\]

then \( \text{ATAN2} (Y, X) \) is
**ATAN2D**

*Elemental Intrinsic Function (Generic):*

*Produces an arctangent. The result is the principal value of the argument of the nonzero complex number \((x, y)\).*

**Syntax**

\[
\text{result} = \text{ATAN2D}(y, x)
\]

- **y**  
  (Input) Must be of type real.
- **x**  
  (Input) Must have the same type and kind parameters as \(y\). If \(y\) has the value zero, \(x\) cannot have the value zero.

**Results**

The result type is the same as \(x\) and is expressed in degrees. The value lies in the range -180 degrees to 180 degrees. If \(x\) zero, the result is approximately equal to the value of \(\arctan\left(\frac{y}{x}\right)\).

If \(y > 0\), the result is positive.

If \(y < 0\), the result is negative.

If \(y = 0\), the result is zero (if \(x > 0\)) or 180 degrees (if \(x < 0\)).

If \(x = 0\), the absolute value of the result is 90 degrees.

<table>
<thead>
<tr>
<th>Specific Name</th>

<td>QATAN2D</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>
Example

ATAN2D (2.679676, 1.0) has the value 69.53546.

ATAND

*Elemental Intrinsic Function (Generic):*

*Produces the arctangent of* $x$.

**Syntax**

```
result = ATAND (x)
```

$x$ (Input) Must be of type real and must be greater than or equal to zero.

**Results**

The result type is the same as $x$ and is expressed in degrees.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAND</td>

<tr>
<td>DATAND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

ATAND (0.0874679) has the value 4.998819.

ATANH

*Elemental Intrinsic Function (Generic):*

*Produces the hyperbolic arctangent of* $x$.

**Syntax**

```
result = ATANH (x)
```

$x$ (Input) Must be of type real, where $|x|$ is less than or equal to 1.
Results
The result type is the same as $x$. The value lies in the range -1.0 to 1.0.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATANH</td>
<td>REAL(4)</td>

<td>DATANH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATANH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example
ATANH (-0.77) has the value -1.02033.
ATANH (0.5) has the value 0.549306.

ATOMIC

OpenMP* Fortran Compiler Directive: Ensures that a specific memory location is updated dynamically; this prevents the possibility of multiple, simultaneous writing threads.

Syntax
c$OMP ATOMIC

Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

The ATOMIC directive permits optimization beyond that of the critical section around the assignment. An implementation can replace ATOMIC directives by enclosing each statement in a critical section. The critical section (or sections) must use the same unique name.

The ATOMIC directive applies only to the immediately following statement, which must have one of the following forms:

x = x operator expr
x = expr operator x
x = intrinsic (x, expr)

In the preceding statements:
• \(x\) is a scalar variable of intrinsic type
• \(expr\) is a scalar expression that does not reference \(x\)
• \(\text{intrinsic}\) is MAX, MIN, IAND, IOR, or Ieor
• \(\text{operator}\) is +, *, -, /, .AND., .OR., .EQV., or .NEQV.

All references to storage location \(x\) must have the same type and type parameters.
Only the loading and storing of \(x\) are dynamic; the evaluation of \(expr\) is not dynamic. To avoid race conditions (or concurrency races), all updates of the location in parallel must be protected using the ATOMIC directive, except those that are known to be free of race conditions. The function \(\text{intrinsic}\), the operator \(\text{operator}\), and the assignment must be the intrinsic function, operator, and assignment.

Example
The following example shows a way to avoid race conditions by using ATOMIC to protect all simultaneous updates of the location by multiple threads:

```fortran
C$OMP PARALLEL DO DEFAULT(PRIVATE) SHARED(X,Y,INDEX,N)
DO I=1,N
    CALL WORK(XLOCAL, YLOCAL)
C$OMP ATOMIC
    X(INDEX(I)) = X(INDEX(I)) + XLOCAL
    Y(I) = Y(I) + YLOCAL
END DO
```

Since the ATOMIC directive applies only to the statement immediately following it, note that \(Y\) is not updated atomically.

\(^1\) A common block name is specified as 
\[/\]common-block-name[/\]

\(^2\) This option can only be applied to arrays.
These options can be used in function and subroutine definitions, in type declarations, and with the INTERFACE and ENTRY statements.

Options applied to entities available through use or host association are in effect during the association. For example, consider the following:

```fortran
MODULE MOD1 INTERFACE
    SUBROUTINE SUB1
        !DEC$ ATTRIBUTES C, ALIAS:'othername' :: NEW_SUB
        END SUBROUTINE
    END INTERFACE
CONTAINS
    SUBROUTINE SUB2
        CALL NEW_SUB
    END SUBROUTINE
END MODULE
```

In this case, the call to NEW_SUB within SUB2 uses the C and ALIAS options specified in the interface block.

The following are ATTRIBUTES options:

- ALIAS
- ALIGN
- ALLOCATABLE
- ALLOW_NULL
- ARRAY_VISUALIZER
- C and STDCALL
OPTIONS

- DECORATE
- DEFAULT
- DLLEXPORT and DLLIMPORT
- EXTERN
- IGNORE_LOC
- INLINE, NOINLINE, and FORCEINLINE
- NO_ARG_CHECK
- NOMIXED_STR_LEN_ARG
- REFERENCE and VALUE
- VARYING

Options C, STDCALL, REFERENCE, VALUE, and VARYING affect the calling conventions of routines:

- You can specify C, STDCALL, REFERENCE, and VARYING for an entire routine.
- You can specify VALUE and REFERENCE for individual arguments.

Examples

INTERFACE

SUBROUTINE For_Sub (I)
  !DEC$ ATTRIBUTES C, ALIAS:_For_Sub :: For_Sub
  INTEGER I
END SUBROUTINE For_Sub

END INTERFACE

You can assign more than one option to multiple variables with the same compiler directive. All assigned options apply to all specified variables. For example:

  !DEC$ ATTRIBUTES REFERENCE, VARYING, C :: A, B, C

In this case, the variables A, B, and C are assigned the REFERENCE, VARYING, and C options. The only restriction on the number of options and variables is that the entire compiler directive must fit on one line.

The identifier of the variable or procedure that is assigned one or more options must be a simple name. It cannot include initialization or array dimensions. For example, the following is not allowed:

  !DEC$ ATTRIBUTES C :: A(10) ! This is illegal.
The following shows another example:

```fortran
SUBROUTINE ARRAYTEST(arr)

!DEC$ ATTRIBUTES DLLEXPORT :: ARRAYTEST

REAL(4) arr(3, 7)
INTEGER i, j
DO i = 1, 3
  DO j = 1, 7
    arr (i, j) = 11.0 * i + j
  END DO
END DO

END SUBROUTINE
```

General Compiler Directives

Programming with Mixed Languages Overview

ATTRIBUTES ALIAS

The ATTRIBUTES directive option ALIAS specifies an alternate external name to be used when referring to external subprograms. It takes the following form:

Syntax

`c$ ATTRIBUTES ALIAS: external-name:: subprogram`

- `c` Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- `external-name` Is a character constant delimited by apostrophes or quotation marks. The character constant is used as is; the string is not changed to uppercase, nor are blanks removed.
- `subprogram` Is an external subprogram.

The ALIAS option overrides the C (and STDCALL) option. If both C and ALIAS are specified for a subprogram, the subprogram is given the C calling convention, but not the C naming convention. It instead receives the name given for ALIAS, with no modifications.

ALIAS cannot be used with internal procedures, and it cannot be applied to dummy arguments.

The following example gives the subroutine happy the name "OtherName@4" outside this scoping unit:

```fortran
INTERFACE

SUBROUTINE happy(i)
    !$c$c ATTRIBUTES STDCALL, DECORATE, ALIAS:'OtherName' :: happy
    INTEGER i
END SUBROUTINE

END INTERFACE
```

`c$ ATTRIBUTES ALIAS has the same effect as the c$ ALIAS directive.`
**ATTRIBUTES ALIGN**

The `ATTRIBUTES` directive option `ALIGN` specifies the byte alignment for a variable. It takes the following form:

**Syntax**

```
c DEC$ ATTRIBUTES ALIGN: n:: var
```

- `c` Is one of the following: C (or c), I, or *. (See Syntax Rules for Compiler Directives.)
- `n` Is the number of bytes for the minimum alignment boundary.
  - For allocatable variables, the boundary value must be a power of 2 between 1 and 16384, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on.
  - For non-allocatable variables, the boundary value must be a power of 2 between 1 and 64 on Windows* systems, between 1 and $2^{16}$ on Linux* systems, or between 1 and $2^{12}$ on Mac OS* X systems.
- `var` Is the variable to be aligned.

**ATTRIBUTES ALLOCATABLE**

The `ATTRIBUTES` directive option `ALLOCATABLE` is provided for compatibility with older programs. It lets you delay allocation of storage for a particular declared entity until some point at run time when you explicitly call a routine that dynamically allocates storage for the entity. The `ALLOCATABLE` option takes the following form:

**Syntax**

```
c DEC$ ATTRIBUTES ALLOCATABLE :: entity
```

- `c` Is one of the following: C (or c), I, or *. (See Syntax Rules for Compiler Directives.)
- `entity` Is the name of the entity that should have allocation delayed.

The recommended method for dynamically allocating storage is to use the `ALLOCATABLE` statement or attribute.
ATTRIBUTES ALLOW_NULL

The ATTRIBUTES directive option ALLOW_NULL enables a corresponding dummy argument to pass a NULL pointer (defined by a zero or the NULL intrinsic) by value for the argument. It takes the following form:

**Syntax**

c DEC$ ATTRIBUTES ALLOW_NULL :: arg

- `c` Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- `arg` Is the name of the argument.

ALLOW_NULL is only valid if the REFERENCE option is also specified; otherwise, it has no effect.

ATTRIBUTES ARRAY_VISUALIZER (W*32, W*64)

The ATTRIBUTES directive option ARRAY_VISUALIZER enables more efficient memory sharing between the application and the Intel® Array Visualizer library. It takes the following form:

**Syntax**

c DEC$ ATTRIBUTES ARRAY_VISUALIZER :: array

- `c` Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- `array` Is the array to be used with the Intel® Array Visualizer library.

The following example shows a way to use this directive option to improve the performance of the call:

```fortran
real(4), allocatable :: MyArray(:, :)

!DEC$ ATTRIBUTES array_visualizer :: MyArray
```

ATTRIBUTES C and STDCALL

The ATTRIBUTES directive options C and STDCALL specify procedure calling, naming, and argument passing conventions. They take the following forms:

**Syntax**

c DEC$ ATTRIBUTES C :: object[, object] ...
cDEC$ ATTRIBUTES STDCALL :: object[, object] ...

c Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

object Is the name of a data object or procedure.

On W*32 only (see Conventions, Platform labels), C and STDCALL have slightly different meanings; on all other platforms, they are interpreted as synonyms.

When applied to a subprogram, these options define the subprogram as having a specific set of calling conventions.

The following table summarizes the differences between the calling conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>C 1</th>
<th>STDCALL 1</th>
<th>Default 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arguments passed by value</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>

</table>
If 

<table>
<thead>
<tr>
<th>Convention</th>
<th>C ¹</th>
<th>STDCALL ¹</th>
<th>Default ²</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable number of arguments</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

¹ C and STDCALL are synonyms on Linux systems.
² The Intel Fortran calling convention
³ On Linux systems, if there are one or more underscores in the external name, two trailing underscores are added; if there are no underscores, one is added.
⁴ W*32 only

If C or STDCALL is specified for a subprogram, arguments (except for arrays and characters) are passed by value. Subprograms using standard Fortran conventions pass arguments by reference.

On IA-32 architecture, an underscore ( _ ) is placed at the beginning of the external name of a subprogram. If STDCALL is specified, an at sign (@) followed by the number of argument bytes being passed is placed at the end of the name. For example, a subprogram named SUB1 that has three INTEGER(4) arguments and is defined with STDCALL is assigned the external name _sub1@12.

Character arguments are passed as follows:

- **By default, hidden lengths are put at the end of the argument list.**

  On Windows* systems using IA-32 architecture, you can get Compaq* Visual Fortran default behavior by specifying compiler option iface.

- **If C or STDCALL (only) is specified:**

  On all systems, the first character of the string is passed (and padded with zeros out to INTEGER(4) length).

- **If C or STDCALL is specified, and REFERENCE is specified for the argument:**

  On all systems, the string is passed with no length.

- **If C or STDCALL is specified, and REFERENCE is specified for the routine (but REFERENCE is not specified for the argument, if any):**

  On all systems, the string is passed with the length.
ATTRIBUTES DECORATE

The ATTRIBUTES directive option DECORATE specifies that the external name used in cDEC$ ALIAS or cDEC$ ATTRIBUTES ALIAS should have the prefix and postfix decorations performed on it that are associated with the calling mechanism that is in effect. These are the same decorations performed on the procedure name when ALIAS is not specified.

Syntax

The DECORATE option takes the following form:

\[
\text{cDEC$ ATTRIBUTES DECORATE :: exname}
\]

- \(c\) is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- \(exname\) is an external name.

The case of the ALIAS external name is not modified.

If ALIAS is not specified, this option has no effect.

See Also

- ATTRIBUTES
- The example in the description of the ATTRIBUTES option ALIAS
- The summary of prefix and postfix decorations in the description of the ATTRIBUTES options C and STDCALL
ATTRIBUTES DEFAULT
The ATTRIBUTES directive option DEFAULT overrides certain compiler options that can affect external routine and COMMON block declarations. It takes the following form:

Syntax

\[
\text{cDEC$ ATTRIBUTES DEFAULT :: entity}
\]

\(c\)
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

\(entity\)
Is an external procedure or COMMON block.

It specifies that the compiler should ignore compiler options that change the default conventions for external symbol naming and argument passing for routines and COMMON blocks (such as names, assume underscore, assume 2underscores on Linux systems, and iface on Windows* systems).

This option can be combined with other ATTRIBUTES options, such as STDCALL, C, REFERENCE, ALIAS, etc. to specify properties different from the compiler defaults.

This option is useful when declaring INTERFACE blocks for external routines, since it prevents compiler options from changing calling or naming conventions.

See Also
• ATTRIBUTES
• names compiler option
• assume compiler option

ATTRIBUTES DLLEXPORT and DLLIMPORT (W*32, W*64)
The ATTRIBUTES directive options DLLEXPORT and DLLIMPORT define a dynamic-link library’s (DLL) interface for processes that use them. The options can be assigned to module variables, COMMON blocks, and procedures. They take the following forms:

Syntax

\[
\text{cDEC$ ATTRIBUTES DLLEXPORT :: object[, object] ...}
\]

\[
\text{cDEC$ ATTRIBUTES DLLIMPORT :: object[, object] ...}
\]
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

Is the name of a module variable, COMMON block, or procedure. The name of a COMMON block must be enclosed in slashes.

DLLEXPORT specifies that procedures or data are being exported to other applications or DLLs. This causes the compiler to produce efficient code, eliminating the need for a module definition (.def) file to export symbols.

DLLEXPORT should be specified in the routine to which it applies.

Symbols defined in a DLL are imported by programs that use them. The program must link with the DLL import library (.lib) and use the DLLIMPORT option inside the program unit that imports the symbol. DLLIMPORT is specified in a declaration, not a definition, since you cannot define a symbol you are importing.

See Also

- ATTRIBUTES
- ATTRIBUTES

Building Applications: Creating and Using Fortran DLLs Overview, for details on working with DLL applications

ATTRIBUTES DLLEXPORT and DLLIMPORT (W*32, W*64)

The ATTRIBUTES directive options DLLEXPORT and DLLIMPORT define a dynamic-link library's (DLL) interface for processes that use them. The options can be assigned to module variables, COMMON blocks, and procedures. They take the following forms:

Syntax

```
c DEC$ ATTRIBUTES DLLEXPORT : : object[, object] ... 
c DEC$ ATTRIBUTES DLLIMPORT : : object[, object] ... 
c Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
object Is the name of a module variable, COMMON block, or procedure. The name of a COMMON block must be enclosed in slashes.
```

DLLEXPORT specifies that procedures or data are being exported to other applications or DLLs. This causes the compiler to produce efficient code, eliminating the need for a module definition (.def) file to export symbols.
DLLEXPORT should be specified in the routine to which it applies.

Symbols defined in a DLL are imported by programs that use them. The program must link with the DLL import library (.lib) and use the DLLIMPORT option inside the program unit that imports the symbol. DLLIMPORT is specified in a declaration, not a definition, since you cannot define a symbol you are importing.

See Also
- ATTRIBUTES
- ATTRIBUTES

Building Applications: Creating and Using Fortran DLLs Overview, for details on working with DLL applications

ATTRIBUTES EXTERN
The ATTRIBUTES directive option EXTERN specifies that a variable is allocated in another source file.
EXTERN can be used in global variable declarations, but it must not be applied to dummy arguments.
It takes the following form:

**Syntax**

c DEC$ ATTRIBUTES EXTERN :: var

* c Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
* var Is the variable to be allocated.

This option must be used when accessing variables declared in other languages.

ATTRIBUTES INLINE, NOINLINE, and FORCEINLINE
The ATTRIBUTES directive options INLINE, NOINLINE, and FORCEINLINE can be used to control inlining decisions made by the compiler.
You should place the directive option in the procedure whose inlining you want to influence.

**Syntax**

The INLINE option specifies that a function or subroutine can be inlined. The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size. It takes the following form:

c DEC$ ATTRIBUTES INLINE :: procedure
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

procedure Is the function or subroutine that can be inlined.

The NOINLINE option disables inlining of a function. It takes the following form:

```c
DEC$ ATTRIBUTES NOINLINE :: procedure
```

See above.

The FORCEINLINE option specifies that a function or subroutine must be inlined unless it will cause errors. It takes the following form:

```c
DEC$ ATTRIBUTES FORCEINLINE :: procedure
```

See above.

ATTRIBUTES IGNORE_LOC

The ATTRIBUTES directive option IGNORE_LOC enables %LOC to be stripped from an argument. It takes the following form:

```c
DEC$ ATTRIBUTES IGNORE_LOC :: arg
```

Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

Is the name of an argument.

IGNORE_LOC is only valid if the REFERENCE option is also specified; otherwise, it has no effect.

ATTRIBUTES INLINE, NOINLINE, and FORCEINLINE

The ATTRIBUTES directive options INLINE, NOINLINE, and FORCEINLINE can be used to control inlining decisions made by the compiler. You should place the directive option in the procedure whose inlining you want to influence.

Syntax

The INLINE option specifies that a function or subroutine can be inlined. The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size. It takes the following form:
cDECS$ ATTRIBUTES INLINE :: procedure

procedure

Is the function or subroutine that can be inlined.

The NOINLINE option disables inlining of a function. It takes the following form:

cDECS$ ATTRIBUTES NOINLINE :: procedure

See above.

procedure

Is the function or subroutine that must not be inlined.

The FORCEINLINE option specifies that a function or subroutine must be inlined unless it will cause errors. It takes the following form:

cDECS$ ATTRIBUTES FORCEINLINE :: procedure

See above.

procedure

Is the function or subroutine that must be inlined.

ATTRIBUTES MIXED_STR_LEN_ARG and NOMIXED_STR_LEN_ARG

These ATTRIBUTES directive options specify where hidden lengths for character arguments and character-valued functions should be placed. MIXED_STR_LEN_ARG specifies that hidden lengths for character arguments and character-valued functions should be placed immediately following the argument address in the argument list. NOMIXED_STR_LEN_ARG specifies that these hidden lengths should be placed in sequential order at the end of the argument list. They take the following form:

Syntax

cDECS$ ATTRIBUTES MIXED_STR_LEN_ARG :: args
cDECS$ ATTRIBUTES NOMIXED_STR_LEN_ARG :: args

c Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

args Is a list of arguments.
The default is NOMIXED_STR_LEN_ARG. However, if you specify compiler option /iface:CVF or /iface:mixed_str_len_arg (Windows), or compiler option -mixed-str-len-arg (Linux and Mac OS X), the default is MIXED_STR_LEN_ARG.

See Also
• ATTRIBUTES
• ATTRIBUTES
• ATTRIBUTES

ATTRIBUTES NO_ARG_CHECK

The ATTRIBUTES directive option NO_ARG_CHECK specifies that type and shape matching rules related to explicit interfaces are to be ignored. This permits the construction of an INTERFACE block for an external procedure or a module procedure that accepts an argument of any type or shape; for example, a memory copying routine. The NO_ARG_CHECK option takes the following form:

Syntax

```
cDEC$ ATTRIBUTES NO_ARG_CHECK :: object
```

- `c` Is one of the following: C (or c), f, or *. (See Syntax Rules for Compiler Directives.)
- `object` Is the name of an argument or procedure.

NO_ARG_CHECK can appear only in an INTERFACE block for a non-generic procedure or in a module procedure. It can be applied to an individual dummy argument name or to the routine name, in which case the option is applied to all dummy arguments in that interface.

NO_ARG_CHECK cannot be used for procedures with the PURE or ELEMENTAL prefix.

• ATTRIBUTES
• ATTRIBUTES
ATTRIBUTES INLINE, NOINLINE, and FORCEINLINE

The ATTRIBUTES directive options INLINE, NOINLINE, and FORCEINLINE can be used to control inlining decisions made by the compiler. You should place the directive option in the procedure whose inlining you want to influence.

Syntax

The INLINE option specifies that a function or subroutine can be inlined. The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size. It takes the following form:

\[ \text{cDEC$ ATTRIBUTES INLINE :: procedure} \]

\[ c \]

Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

procedure

Is the function or subroutine that can be inlined.

The NOINLINE option disables inlining of a function. It takes the following form:

\[ \text{cDEC$ ATTRIBUTES NOINLINE :: procedure} \]

\[ c \]

See above.

procedure

Is the function or subroutine that must not be inlined.

The FORCEINLINE option specifies that a function or subroutine must be inlined unless it will cause errors. It takes the following form:

\[ \text{cDEC$ ATTRIBUTES FORCEINLINE :: procedure} \]

\[ c \]

See above.

procedure

Is the function or subroutine that must be inlined.

ATTRIBUTES MIXED_STR_LEN_ARG and NOMIXED_STR_LEN_ARG

These ATTRIBUTES directive options specify where hidden lengths for character arguments and character-valued functions should be placed. MIXED_STR_LEN_ARG specifies that hidden lengths for character arguments and character-valued functions should be placed immediately following the argument address in the argument list. NOMIXED_STR_LEN_ARG specifies that these
hidden lengths should be placed in sequential order at the end of the argument list. They take the following form:

Syntax

cDEC$ ATTRIBUTES MIXED_STR_LEN_ARG :: args
cDEC$ ATTRIBUTES NOMIXED_STR_LEN_ARG :: args

c
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

args
Is a list of arguments.

The default is NOMIXED_STR_LEN_ARG. However, if you specify compiler option /iface:CVF or /iface:mixed_str_len_arg (Windows), or compiler option -mixed-str-len-arg (Linux and Mac OS X), the default is MIXED_STR_LEN_ARG.

See Also

• ATTRIBUTES
• ATTRIBUTES
• ATTRIBUTES

ATTRIBUTES REFERENCE and VALUE

The ATTRIBUTES directive options REFERENCE and VALUE specify how a dummy argument is to be passed. They take the following form:

Syntax

cDEC$ ATTRIBUTES REFERENCE :: arg

cDEC$ ATTRIBUTES VALUE :: arg

\(c\)
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

\(arg\)
Is the name of a dummy argument.

REFERENCE specifies a dummy argument's memory location is to be passed instead of the argument's value.

VALUE specifies a dummy argument's value is to be passed instead of the argument's memory location.
When VALUE is specified for a dummy argument, the actual argument passed to it can be of a
different type. If necessary, type conversion is performed before the subprogram is called.

When a complex (KIND=4 or KIND=8) argument is passed by value, two floating-point
arguments (one containing the real part, the other containing the imaginary part) are passed
by immediate value.

Character values, substrings, assumed-size arrays, and adjustable arrays cannot be passed by
value.

If REFERENCE (only) is specified for a character argument, the string is passed with no length.

If REFERENCE is specified for a character argument, and C (or STDCALL) has been specified
for the routine, the string is passed with no length. This is true even if REFERENCE is also
specified for the routine.

If REFERENCE and C (or STDCALL) are specified for a routine, but REFERENCE has not been
specified for the argument, the string is passed with the length.

VALUE is the default if the C or STDCALL option is specified in the subprogram definition.

In the following example integer x is passed by value:

```fortran
SUBROUTINE Subr (x)
    INTEGER x
!DEC$ ATTRIBUTES VALUE :: x
```

Building Applications: Adjusting Calling Conventions in Mixed-Language Programming Overview

ATTRIBUTES C and STDCALL

The ATTRIBUTES directive options C and STDCALL
specify procedure calling, naming, and argument
passing conventions. They take the following
forms:

Syntax

```fortran
cDEC$ ATTRIBUTES C :: object[, object] ...
cDEC$ ATTRIBUTES STDCALL :: object[, object] ...
```
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

Object

Is the name of a data object or procedure.

On W*32 only (see Conventions, Platform labels), C and STDCALL have slightly different meanings; on all other platforms, they are interpreted as synonyms.

When applied to a subprogram, these options define the subprogram as having a specific set of calling conventions.

The following table summarizes the differences between the calling conventions:

<table>
<thead>
<tr>
<th>Convention</th>

<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

---

2391
If C or STDCALL is specified for a subprogram, arguments (except for arrays and characters) are passed by value. Subprograms using standard Fortran conventions pass arguments by reference.

On IA-32 architecture, an underscore ( _ ) is placed at the beginning of the external name of a subprogram. If STDCALL is specified, an at sign (@) followed by the number of argument bytes being passed is placed at the end of the name. For example, a subprogram named SUB1 that has three INTEGER(4) arguments and is defined with STDCALL is assigned the external name _sub1@12.

Character arguments are passed as follows:

- By default, hidden lengths are put at the end of the argument list.
  
  On Windows* systems using IA-32 architecture, you can get Compaq* Visual Fortran default behavior by specifying compiler option iface.

- If C or STDCALL (only) is specified:
  
  On all systems, the first character of the string is passed (and padded with zeros out to INTEGER(4) length).

- If C or STDCALL is specified, and REFERENCE is specified for the argument:
  
  On all systems, the string is passed with no length.

- If C or STDCALL is specified, and REFERENCE is specified for the routine (but REFERENCE is not specified for the argument, if any):
  
  On all systems, the string is passed with the length.

Building Applications: Adjusting Calling Conventions in Mixed-Language Programming Overview

ATTRIBUTES REFERENCE and VALUE

The ATTRIBUTES directive options REFERENCE and VALUE specify how a dummy argument is to be passed. They take the following form:

Syntax

```c
DEC\$ ATTRIBUTES REFERENCE :: arg
DEC\$ ATTRIBUTES VALUE :: arg
```

- `c` is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- `arg` is the name of a dummy argument.

REFERENCE specifies a dummy argument's memory location is to be passed instead of the argument's value.

VALUE specifies a dummy argument's value is to be passed instead of the argument's memory location.

When VALUE is specified for a dummy argument, the actual argument passed to it can be of a different type. If necessary, type conversion is performed before the subprogram is called.

When a complex (KIND=4 or KIND=8) argument is passed by value, two floating-point arguments (one containing the real part, the other containing the imaginary part) are passed by immediate value.

Character values, substrings, assumed-size arrays, and adjustable arrays cannot be passed by value.

If REFERENCE (only) is specified for a character argument, the string is passed with no length.

If REFERENCE is specified for a character argument, and C (or STDCALL) has been specified for the routine, the string is passed with no length. This is true even if REFERENCE is also specified for the routine.
If REFERENCE and C (or STDCALL) are specified for a routine, but REFERENCE has not been specified for the argument, the string is passed with the length. 

VALUE is the default if the C or STDCALL option is specified in the subprogram definition.

In the following example integer x is passed by value:

```fortran
SUBROUTINE Subr (x)
  INTEGER x

!DEC$ ATTRIBUTES VALUE :: x
```

Building Applications: Adjusting Calling Conventions in Mixed-Language Programming Overview

ATTRIBUTES VARYING

The ATTRIBUTES directive option VARYING allows a variable number of calling arguments. It takes the following form:

**Syntax**

```fortran
DEC$ ATTRIBUTES VARYING :: var[, var] ...
```

- `c` Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- `var` Is the name of a variable.

Either the first argument must be a number indicating how many arguments to process, or the last argument must be a special marker (such as -1) indicating it is the final argument. The sequence of the arguments, and types and kinds must be compatible with the called procedure. If VARYING is specified, the C option must also be specified.

**AUTOAddArg (W*32, W*64)**

**AUTO Subroutine:** Passes an argument name and value and adds the argument to the argument list data structure.

**Module**

USE IFAUTO
USE IFWINTY

**Syntax**

CALL AUTOAddArg (invoke_args, name, value[,intent_arg][,type])

*invoke_args*  
The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

*name*  
The argument's name of type CHARACTER(*).*

*value*  
The argument's value. Must be of type INTEGER(1), INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), CHARACTER(*), or a single dimension array of one of these types. Can also be of type VARIANT, which is defined in the IFWINTY module.

*intent_arg*  
Indicates the intended use of the argument by the called method. Must be one of the following constants defined in the IFAUTO module:

- **AUTO_ARG_IN:** The argument's value is read by the called method, but not written. This is the default value if *intent_arg* is not specified.
- **AUTO_ARG_OUT:** The argument's value is written by the called method, but not read.
- **AUTO_ARG_INOUT:** The argument's value is read and written by the called method.

When the value of *intent_arg* is **AUTO_ARG_OUT** or **AUTO_ARG_INOUT**, the variable used in the *value* argument should be declared using the VOLATILE attribute. This is because the value of the variable will be changed by the subsequent call to AUTOInvoke. The compiler's global optimizations need to know that the value can change unexpectedly.
The variant type of the argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER*(*)</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VT_VARIANT</td>
<td>TYPE(VARIANT)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

Example
See the example in COMInitialize.
**AUTOAllocateInvokeArgs (W*32, W*64)**

**AUTO Function:** Allocates an argument list data structure that holds the arguments to be passed to AUTOInvoke.

**Module**

USE IFAUTO

**Syntax**

```
result = AUTOAllocateInvokeArgs()
```

**Results**

The value returned is an argument list data structure of type INTEGER(INT_PTR_KIND()).

**Example**

See the example in COMInitialize.

**AUTODeallocateInvokeArgs (W*32, W*64)**

**AUTO Subroutine:** Deallocates an argument list data structure.

**Module**

USE IFAUTO

**Syntax**

```
CALL AUTODeallocateInvokeArgs (invoke_args)
```

**invoke_args**

The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Example**

See the example in COMInitialize.
**AUTOGetExceptInfo (W*32, W*64)**

**AUTO Subroutine:** Retrieves the exception information when a method has returned an exception status.

**Module**

USE IFAUTO

**Syntax**

CALL AUTOGetExceptInfo
(invoke_args, code, source, description, h_file, h_context, scode)

- **invoke_args** The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).
- **code** An output argument that returns the error code. Must be of type INTEGER(2).
- **source** An output argument that returns a human-readable name of the source of the exception. Must be of type CHARACTER*(*)..
- **description** An output argument that returns a human-readable description of the error. Must be of type CHARACTER*(*).. 
- **h_file** An output argument that returns the fully qualified path of a Help file with more information about the error. Must be of type CHARACTER*(*)..
- **h_context** An output argument that returns the Help context of the topic within the Help file. Must be of type INTEGER(4).
- **scode** An output argument that returns an SCODE describing the error. Must be of type INTEGER(4).

**AUTOGetProperty (W*32, W*64)**

**AUTO Function:** Passes the name or identifier of the property and gets the value of the automation object's property.

**Module**

USE IFAUTO

USE IFWINTY
**Syntax**

```plaintext
result = AUTOGetProperty (idispatch, id, value[, type])
```

- **idispatch**: The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- **id**: The argument's name of type CHARACTER*(*) or its member ID of type INTEGER(4).
- **value**: An output argument that returns the argument's value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER*(*) or a single dimension array of one of these types.
- **type**: The variant type of the requested argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER*(*)</td>
</tr>
<tr>
<td>VT_DISPATCH</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_ERROR</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_BOOL</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>VT_UNKNOWN</td>
<td>INTEGER(4)</td>
</tr>
</tbody>
</table>

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).
AUTOGetPropertyByID (W*32, W*64)

**AUTO Function**: Passes the member ID of the property and gets the value of the automation object's property into the argument list's first argument.

**Module**
USE IFAUTO

**Syntax**

```fortran
result = AUTOGetPropertyByID (idispatch, memid, invoke_args)
```

- `idispatch` The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- `memid` Member ID of the property. Must be of type INTEGER(4).
- `invoke_args` The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

AUTOGetPropertyInvokeArgs (W*32, W*64)

**AUTO Function**: Passes an argument list data structure and gets the value of the automation object's property specified in the argument list's first argument.

**Module**
USE IFAUTO

**Syntax**

```fortran
result = AUTOGetPropertyInvokeArgs (idispatch, invoke_args)
```

- `idispatch` The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- `invoke_args` The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).
**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(INT_PTR_KIND()).

**AUTOInvoke (W*32, W*64)**

**AUTO Function:** Passes the name or identifier of an object's method and an argument list data structure and invokes the method with the passed arguments.

**Module**

USE IFAUTO

**Syntax**

result = AUTOInvoke (idispacht, id, invoke_args)

- idispacht: The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- id: The argument's name of type CHARACTER*(*) or its member ID of type INTEGER(4).
- invoke_args: The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**Example**

See the example in COMInitialize.
AUTOMATIC

**Statement and Attribute:** Controls the storage allocation of variables in subprograms (as does STATIC). Variables declared as AUTOMATIC and allocated in memory reside in the stack storage area, rather than at a static memory location.

**Syntax**

The AUTOMATIC attribute can be specified in a type declaration statement or an AUTOMATIC statement, and takes one of the following forms:

**Type Declaration Statement:**

type, [att-ls] AUTOMATIC [, att-ls] :: v[, v] ...

**Statement:**

AUTOMATIC [::] v[, v] ...

type Is a data type specifier.

att-ls Is an optional list of attribute specifiers.

v Is the name of a variable or an array specification. It can be of any type.

AUTOMATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.

Automatic variables can reduce memory use because only the variables currently being used are allocated to memory.

Automatic variables allow possible recursion. With recursion, a subprogram can call itself (directly or indirectly), and resulting values are available upon a subsequent call or return to the subprogram. For recursion to occur, RECURSIVE must be specified in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
- As an option in an OPTIONS statement
By default, the compiler allocates local scalar variables on the stack. Other non-allocatable variables of non-recursive subprograms are allocated in static storage by default. This default can be changed through compiler options. Appropriate use of the SAVE attribute may be required if your program assumes that local variables retain their definition across subprogram calls.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE (in one of the ways mentioned above).

To override any compiler option that may affect variables, explicitly specify the variables as AUTOMATIC.

**NOTE.** Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as AUTOMATIC more than once in the same scoping unit.

If the variable is a pointer, AUTOMATIC applies only to the pointer itself, not to any associated target.

Some variables cannot be specified as AUTOMATIC. The following table shows these restrictions:

<table>
<thead>
<tr>
<th>Variable</th>
<th>AUTOMATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dummy argument</td>
<td>No</td>
</tr>
<tr>
<td>Automatic object</td>
<td>No</td>
</tr>
<tr>
<td>Common block item</td>
<td>No</td>
</tr>
<tr>
<td>Use-associated item</td>
<td>No</td>
</tr>
<tr>
<td>Function result</td>
<td>No</td>
</tr>
<tr>
<td>Component of a derived type</td>
<td>No</td>
</tr>
</tbody>
</table>

If a variable is in a module's outer scope, it cannot be specified as AUTOMATIC.

**Example**

The following example shows a type declaration statement specifying the AUTOMATIC attribute:

```fortran
REAL, AUTOMATIC :: A, B, C
```
The following example uses an AUTOMATIC statement:

```fortran
CONTAINS

INTEGER FUNCTION REDO_FUNC
    INTEGER I, J(10), K
    REAL C, D, E(30)
    AUTOMATIC I, J, K(20)
    STATIC C, D, E

END FUNCTION

SUBROUTINE DoIt (arg1, arg2)
    INTEGER(4) arg1, arg2
    INTEGER(4) var1, var2, var3, var4
    SAVE
    AUTOMATIC var1, var3

END SUBROUTINE
```

In this example, all variables within the program unit are saved, except for "var1" and "var3". These are explicitly declared in an AUTOMATIC statement, and thus have memory locations on the stack:

```fortran
SUBROUTINE DoIt (arg1, arg2)
    INTEGER(4) arg1, arg2
    INTEGER(4) var1, var2, var3, var4
    SAVE
    AUTOMATIC var1, var3

END SUBROUTINE
```

var2 and var4 are saved

**AUTOSetProperty (W*32, W*64)**

**AUTO Function:** Passes the name or identifier of the property and a value, and sets the value of the automation object's property.

**Module**

USE IFAUTO
USE IFWINTY

**Syntax**

```
result = AUTOSetProperty (idispatch, id, value[, type])
```

- `idispatch`: The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- `id`: The argument's name of type CHARACTER*(*) or its member ID of type INTEGER(4).
- `value`: The argument's value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER*(*) or a single dimension array of one of these types.
- `type`: The variant type of the argument. Must be one of the following constants defined in the IFWINTY module:

<table>
<thead>
<tr>
<th>VARIANT Type</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VT_I2</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>VT_I4</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>VT_R4</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>VT_R8</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_CY</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_DATE</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>VT_BSTR</td>
<td>CHARACTER*(*)</td>
</tr>
</tbody>
</table>
### Records

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**AUTOSetPropertyByID (W*32, W*64)**

**AUTO Function:** Passes the member ID of the property and sets the value of the automation object's property into the argument list's first argument.

**Module**

USE IFAUTO

**Syntax**

```fortran
result = AUTOSetPropertyByID (idispatch, memid, invoke_args)
```

- **idispatch**
  The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- **memid**
  Member ID of the property. Must be of type INTEGER(4).
- **invoke_args**
  The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).
AUTOSetPropertyInvokeArgs (W*32, W*64)

**AUTO Function**: Passes an argument list data structure and sets the value of the automation object's property specified in the argument list's first argument.

**Module**

USE IFAUTO

**Syntax**

\[
\text{result} = \text{AUTOSetPropertyInvokeArgs}(\text{idispatch}, \text{invoke_args})
\]

- **idispatch**: The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- **invoke_args**: The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

**Results**

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

**BACKSPACE**

**Statement**: Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing. It takes one of the following forms:

**Syntax**

```
BACKSPACE [(UNIT=]io-unit[, ERR=label] [, IOSTAT=i-var])
```

- **io-unit**: (Input) Is an external unit specifier.
- **label**: Is the label of the branch target statement that receives control if an error occurs.
- **i-var**: (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.
Description

The I/O unit number must specify an open file on disk or magnetic tape.

Backspacing from the current record \( n \) is performed by rewinding to the start of the file and then performing \( n - 1 \) successive READs to reach the previous record.

A BACKSPACE statement must not be specified for a file that is open for direct or append access, because \( n \) is not available to the Fortran I/O system.

BACKSPACE cannot be used to skip over records that have been written using list-directed or namelist formatting.

If a file is already positioned at the beginning of a file, a BACKSPACE statement has no effect.

If the file is positioned between the last record and the end-of-file record, BACKSPACE positions the file at the start of the last record.

Example

```
BACKSPACE 5
BACKSPACE (5)
BACKSPACE lunit
BACKSPACE (UNIT = lunit, ERR = 30, IOSTAT = ios)
```

The following statement repositions the file connected to I/O unit 4 back to the preceding record:

```
BACKSPACE 4
```

Consider the following statement:

```
BACKSPACE (UNIT=9, IOSTAT=IOS, ERR=10)
```

This statement positions the file connected to unit 9 back to the preceding record. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.

- REWIND
- ENDFILE
- Data Transfer I/O Statements
- Branch Specifiers
**BADDRESS**

*Inquiry Intrinsic Function (Generic):* Returns the address of x. This function cannot be passed as an actual argument. This function can also be specified as IADDR.

**Syntax**

result = BADDRESS (x)

x

Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

**Example**

PROGRAM batest
    INTEGER X(5), I
    DO I=1, 5
        PRINT *, BADDRESS(X(I))
    END DO
END

**BARRIER**

*OpenMP® Fortran Compiler Directive:* Synchronizes all the threads in a team. It causes each thread to wait until all of the other threads in the team have reached the barrier.

**Syntax**

c$OMP BARRIER
The BARRIER directive must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.

Example
The directive binding rules call for a BARRIER directive to bind to the closest enclosing PARALLEL directive. In the following example, the BARRIER directive ensures that all threads have executed the first loop and that it is safe to execute the second loop:

```fortran
C$OMP PARALLEL
  C$OMP DO PRIVATE(i)
    DO i = 1, 100
      b(i) = i
    END DO
  C$OMP BARRIER
  C$OMP DO PRIVATE(i)
    DO i = 1, 100
      a(i) = b(101-i)
    END DO
C$OMP END PARALLEL
```

BEEPQQ

*Portability Subroutine:* Sounds the speaker at the specified frequency for the specified duration in milliseconds.

Module

USE IFPORT
Syntax
CALL BEEPQQ (frequency, duration)

frequency (Input) INTEGER(4). Frequency of the tone in Hz.
duration (Input) INTEGER(4). Length of the beep in milliseconds.

BEEPQQ does not return until the sound terminates.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
INTEGER(4) frequency, duration
frequency = 4000
duration = 1000
CALL BEEPQQ(frequency, duration)

See Also
• A to B
• SLEEPQQ

BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN

Portability Functions: Compute the single-precision values of Bessel functions of the first and second kinds.

Module
USE IFPORT

Syntax
result = BESJ0 (value)
result = BESJ1 (value)
result = BESJN (n, value)
result = BESY0 (posvalue)
result = BESY1 (posvalue)
result = BESYN (n, value)

value (Input) REAL(4). Independent variable for a Bessel function.
n (Input) INTEGER(4). Specifies the order of the selected Bessel function computation.
posvalue (Input) REAL(4). Independent variable for a Bessel function. Must be greater than or equal to zero.

Results
BESJ0, BESJ1, and BESJN return Bessel functions of the first kind, orders 0, 1, and \( n \), respectively, with the independent variable \( \text{posvalue} \).

BESY0, BESY1, and BESYN return Bessel functions of the second kind, orders 0, 1, and \( n \), respectively, with the independent variable \( \text{posvalue} \).

Negative arguments cause BESY0, BESY1, and BESYN to return QNAN.

Bessel functions are explained more fully in most mathematics reference books, such as the Handbook of Mathematical Functions (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• A to B
• DBESJ0, DBESJ1, DBESJN

BIC, BIS
Portability Subroutines: Perform a bit-level set and clear for integers.

Module
USE IFPORT

Syntax
CALL BIC (bitnum, target)
CALL BIS (bitnum, target)

bitnum  (Input) INTEGER(4). Bit number to set. Must be in the range 0 (least significant bit) to 31 (most significant bit) if target is INTEGER(4). If target is INTEGER(8), bitnum must be in range 0 to 63.

target  (Input) INTEGER(4) or INTEGER(8). Variable whose bit is to be set.

BIC sets bit bitnum of target to 0; BIS sets bit bitnum to 1.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

Consider the following:

USE IFPORT

integer(4) bitnum, target_i4

integer(8) target_i8

target_i4 = Z'AAAA'

bitnum = 1

call BIC(bitnum, target_i4)

target_i8 = Z'FFFFFFFF00000000'

bitnum = 40

call BIC(bitnum, target_i8)

bitnum = 0

call BIS(bitnum, target_i4)
bitnum = 1

call BIS(bitnum, target_i8)

print '(" integer*4 result ",Z")', target_i4

print '(" integer*8 result ",Z")', target_i8

end

**BIND**

**Statement and Attribute:** Specifies that an object is interoperable with C and has external linkage.

**Syntax**

The BIND attribute can be specified in a type declaration statement or a BIND statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls, ] BIND (C [, NAME=ext-name]) [att-ls,] :: object
```

**Statement:**

```
BIND (C [, NAME=ext-name]) [::] object
```

- **type** Is a data type specifier.
- **att-ls** Is an optional list of attribute specifiers.
- **ext-name** Is a character scalar initialization expression that can be used to construct the external name.
- **object** Is the name of a variable, common block, or procedure.

**Description**

If a common block is specified in a BIND statement, it must be specified with the same binding label in each scoping unit in which it is declared.
For variables and common blocks, BIND also implies the SAVE attribute, which may be explicitly confirmed with SAVE.

A variable given the BIND attribute (or declared in a BIND statement) must appear in the specification part of a module. You cannot specify BIND for a subroutine local variable or a variable in a main program.

The BIND attribute is similar to directive !DEC$ ATTRIBUTES C as follows:

- The compiler applies the same naming rules, that is, names are lowercase (unless NAME= specifies otherwise).
- The compiler applies the appropriate platform decoration, such as a leading underscore.

However, procedure argument passing differs. When BIND is specified, procedure arguments are passed by reference unless the VALUE attribute is also specified.

The BIND attribute can be used in a SUBROUTINE or FUNCTION declaration.

**Example**

The following example shows the BIND attribute used in a type declaration statement, a statement, and a SUBROUTINE statement.

```plaintext
INTEGER, BIND(C) :: SOMEVAR

BIND(C,NAME='SharedCommon') :: /SHAREDCOMMON/

INTERFACE

SUBROUTINE FOOBAR, BIND(C, NAME='FooBar')
END SUBROUTINE

END INTERFACE
```

BIT

Portability Function: Performs a bit-level test for integers.

Module
USE IFPORT

Syntax
result = BIT (bitnum, source)

bitnum (Input) INTEGER(4). Bit number to test. Must be in the range 0 (least significant bit) to 31 (most significant bit).

source (Input) INTEGER(4) or INTEGER(8). Variable being tested.

Results
The result type is logical. It is .TRUE. if bit bitnum of source is 1; otherwise, .FALSE..

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• A to B
• BIC, BIS

BIT_SIZE

Inquiry Intrinsic Function (Generic): Returns the number of bits in an integer type.

Syntax
result = BIT_SIZE (i)

i (Input) Must be of type integer or of type logical (which is treated as an integer).
Results
The result is a scalar integer with the same kind parameter as \( i \). The result value is the number of bits \( s \) defined by the bit model for integers with the kind parameter of the argument. For information on the bit model, see Model for Bit Data.

Example
BIT_SIZE (1_2) has the value 16 because the KIND=2 integer type contains 16 bits.

BLOCK DATA
Statement: Identifies a block-data program unit, which provides initial values for nonpointer variables in named common blocks.

Syntax
BLOCK DATA [name]

[specification-part]

BLOCK DATA [BLOCK DATA [name]]

name
specification-part Is the name of the block data program unit.

Is one or more of the following statements:

<table>
<thead>
<tr>
<th>COMMON</th>
<th>INTRINSIC</th>
<th>STATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA</td>
<td>PARAMETER</td>
<td>TARGET</td>
</tr>
<tr>
<td>Derived-type definition</td>
<td>POINTER</td>
<td>Type declaration (^2)</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>RECORD(^1)</td>
<td>USE (^3)</td>
</tr>
</tbody>
</table>
A block data program unit need not be named, but there can only be one unnamed block data
program unit in an executable program.

If a name follows the END statement, it must be the same as the name specified in the BLOCK
DATA statement.

An interface block must not appear in a block data program unit and a block data program unit
must not contain any executable statements.

If a DATA statement initializes any variable in a named common block, the block data program
unit must have a complete set of specification statements establishing the common block.
However, all of the variables in the block do not have to be initialized.

A block data program unit can establish and define initial values for more than one common
block, but a given common block can appear in only one block data program unit in an executable
program.

The name of a block data program unit can appear in the EXTERNAL statement of a different
program unit to force a search of object libraries for the block data program unit at link time.

\footnote{For more information, see RECORD statement and record structure declarations.}

\footnote{Can only contain attributes: DIMENSION, INTRINSIC, PARAMETER, POINTER, SAVE, STATIC, or TARGET.}

\footnote{Allows access to only named constants.}
Example

The following shows a block data program unit:

```fortran
BLOCK DATA BLKDAT
    INTEGER S,X
    LOGICAL T,W
    DOUBLE PRECISION U
    DIMENSION R(3)
    COMMON /AREA1/R,S,U,T /AREA2/W,X,Y
    DATA R/1.0,2*2.0/, T/.FALSE./, U/0.214537D-7/, W/.TRUE./, Y/3.5/
END
```

The following shows another example:

```fortran
C Main Program
    CHARACTER(LEN=10) LakeType
    REAL X(10), Y(4)
    COMMON/Lakes/a,b,c,d,e,family/Blk2/x,y
...
C The following block-data subprogram initializes
C the named common block /Lakes/:  

C BLOCK DATA InitLakes
    COMMON /Lakes/ erie, huron, michigan, ontario,
           + superior, fname
    DATA erie, huron, michigan, ontario, superior /1, 2, 3, 4, 5/
    CHARACTER(LEN=10) fname/'GreatLakes'/
END
```

BSEARCHQQ

**Portability Function:** Performs a binary search of a sorted one-dimensional array for a specified element. The array elements cannot be derived types or structures.

**Module**

USE IFPORT

**Syntax**

```
result = BSEARCHQQ (adrkey, adrarray, length, size)
```

- **adrkey** (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. Address of the variable containing the element to be found (returned by LOC).
- **adrarray** (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. Address of the array (returned by LOC).
- **length** (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. Number of elements in the array.
- **size** (Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in IFPORT.F90, specify type and kind for numeric arrays:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
</tbody>
</table>
If the value provided in `size` is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with `size` characters per element.

**Results**

The result type is `INTEGER(4)`. It is an array index of the matched entry, or 0 if the entry is not found.

The array must be sorted in ascending order before being searched.

---

**CAUTION.** The location of the array and the element to be found must both be passed by address using the LOC function. This defeats Fortran type checking, so you must make certain that the `length` and `size` arguments are correct, and that `size` is the same for the element to be found and the array searched.

If you pass invalid arguments, BSEARCHQQ attempts to search random parts of memory. If the memory it attempts to search is not allocated to the current process, the program is halted, and you receive a General Protection Violation message.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
USE IFPORT
INTEGER(4) array(10), length
INTEGER(4) result, target
length = SIZE(array)
...
result = BSEARCHQQ(LOC(target), LOC(array), length, SRT$INTEGER4)
```

BTEST

**Elemental Intrinsic Function (Generic):** Tests a bit of an integer argument.

**Syntax**

\[
\text{result} = \text{BTEST}(i, \text{pos})
\]

- \(i\) (Input) Must be of type integer or of type logical (which is treated as an integer).
- \(\text{pos}\) (Input) Must be of type integer. It must not be negative and it must be less than \(\text{BIT\_SIZE}(i)\). The rightmost (least significant) bit of \(i\) is in position 0.

**Results**

The result type is default logical.

The result is true if bit \(\text{pos}\) of \(i\) has the value 1. The result is false if \(\text{pos}\) has the value zero.

For more information, see Bit Functions.

For information on the model for the interpretation of an integer value as a sequence of bits, see Model for Bit Data.

The setting of compiler options specifying integer size can affect this function.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BBTEST</td>
<td>INTEGER(1)</td>
<td>LOGICAL(1)</td>
</tr>
<tr>
<td>BITEST(^1)</td>
<td>INTEGER(2)</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>BTEST(^2)</td>
<td>INTEGER(4)</td>
<td>LOGICAL(4)</td>
</tr>
<tr>
<td>BKTEST</td>
<td>INTEGER(8)</td>
<td>LOGICAL(8)</td>
</tr>
</tbody>
</table>

\(^1\)Or HTEST
Example

BTEST (9, 3) has the value true.

If A has the value

\[
\begin{pmatrix}
1 & 2 \\
3 & 4 \\
\end{pmatrix}
\]

the value of BTEST (A, 2) is

\[
\begin{pmatrix}
\text{false} & \text{false} \\
\text{false} & \text{true} \\
\end{pmatrix}
\]

and the value of BTEST (2, A) is

\[
\begin{pmatrix}
\text{true} & \text{false} \\
\text{false} & \text{false} \\
\end{pmatrix}
\]

The following shows more examples:

<table>
<thead>
<tr>
<th>Function reference</th>
<th>Value of (i)</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>BTEST ((i,2))</td>
<td>00011100 0111000</td>
<td>.FALSE.</td>
</tr>
<tr>
<td>BTEST ((i,3))</td>
<td>00011100 0111000</td>
<td>.TRUE.</td>
</tr>
</tbody>
</table>

The following shows another example:

```fortran
INTEGER(1) i(2)
LOGICAL result(2)
i(1) = 2#10101010
i(2) = 2#01010101
result = BTEST(i, (/3,2/)) ! returns (.TRUE.,.TRUE.)
write(*,*) result
```

**C to D**

**C_ASSOCIATED**

*Intrinsic Module Inquiry function (Generic):* Indicates the association status of one argument, or whether two arguments are associated with the same entity.

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

```fortran
result = C_ASSOCIATED(c_ptr_1[, c_ptr_2])
```

- `c_ptr_1` (Input) is a scalar of derived type C_PTR or C_FUNPTR.
- `c_ptr_2` (Optional; input) is a scalar of the same type as `c_ptr_1`. 
Results
The result is a scalar of type default logical. The result value is one of the following:

- If only $c\_ptr\_1$ is specified, the result is false if $c\_ptr\_1$ is a C null pointer; otherwise, the result is true.
- If $c\_ptr\_2$ is specified, the result is false if $c\_ptr\_1$ is a C null pointer. The result is true if $c\_ptr\_1$ is equal to $c\_ptr\_2$; otherwise, the result is false.

C_F_POINTER
Intrinsic Module Subroutine: Associates a pointer with the target of a C pointer and specifies its shape.

Module
USE, INTRINSIC :: ISO_C_BINDING

Syntax
CALL C_F_POINTER($cptr$, $fptr$ [, $shape$])

$cptr$ (Input) Is a scalar of derived type C_PTR. Its value is the C address of an interoperable data entity, or the result of a reference to function C_LOC with a noninteroperable argument. If the value of $cptr$ is the C address of a Fortran variable, it must have the TARGET attribute.

$fptr$ (Output) Is a pointer. If it is an array, $shape$ must be specified.

$shape$ (Optional, input) Must be of type integer and rank one. Its size equals the rank of $fptr$.

If the value of $cptr$ is the C address of an interoperable data entity, $fptr$ must be a pointer with type and type parameters interoperable with the type of the entity. In this case, $fptr$ becomes pointer-associated with the target of $cptr$.

If $fptr$ is an array, it has the shape specified by $shape$ and each lower bound is 1.
If the value of \textit{cptr} is the result of a reference to \texttt{C\_LOC} with a noninteroperable argument \textit{x}, the following rules apply:

- \texttt{C\_LOC} argument \textit{x} (or its target) must not have been deallocated or have become undefined due to the execution of a \texttt{RETURN} or \texttt{END} statement since the reference to \texttt{C\_LOC}.
- \textit{fp\_ptr} is a scalar pointer with the same type and type parameters as \textit{x}. \textit{fp\_ptr} becomes pointer-associated with \textit{x}, or it becomes pointer-associated with its target if \textit{x} is a pointer.

\textbf{See Also}
- C to D
- Intrinsic Modules
- ISO\_C\_BINDING Module
- C\_LOC

\textbf{C\_F\_PROCPOINTER}

\emph{Intrinsic Module Subroutine:} Associates a Fortran pointer of type \texttt{INTEGER} with the target of a C function pointer.

\textbf{Module}

\texttt{USE, INTRINSIC :: ISO\_C\_BINDING}

\textbf{Syntax}

\begin{verbatim}
CALL C\_F\_POINTER(cptr, fptr)
\end{verbatim}

\textit{cptr} \hspace{1cm} (Input) Is a scalar of derived type \texttt{C\_FUNPTR}. Its value is the C address of a procedure that is interoperable.

\textit{fptr} \hspace{1cm} (Output) Is a Fortran pointer of type \texttt{INTEGER}. It becomes pointer-associated with the target of \textit{cptr}.

\textbf{See Also}
- C to D
- Intrinsic Modules
- ISO\_C\_BINDING Module
**C_FUNLOC**  
*Intrinsic Module Inquiry function (Generic): Returns the C address of a function pointer.*

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

result = C_FUNLOC(x)  

(x) (Input) Is an interoperable procedure or a Fortran pointer of type INTEGER associated with an interoperable procedure.

**Results**

The result is a scalar of derived type C_FUNPTR. The result value represents the C address of the argument.

**See Also**

- C to D
- Intrinsic Modules
- ISO_C_BINDING Module

**C_LOC**  
*Intrinsic Module Inquiry function (Generic): Returns the C address of an argument.*

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

result = C_LOC(x)  

(x) (Input) Is one of the following:

- An interoperable variable that has the TARGET attribute
- An interoperable, allocatable, variable that is allocated, has the TARGET attribute, and is not an array of size zero
• An associated, interoperable scalar pointer
• A scalar that has no length type parameters and is one of the following:
  • A nonallocatable, nonpointer variable that has the TARGET attribute
  • An allocatable variable that is allocated and has the TARGET attribute
  • An associated pointer

Results
The result is a scalar of derived type C_PTR. The result value represents the C address of the argument.

The result is a value that can be used as an actual CPTR argument in a call to procedure C_F_Pointer where $fptr$ has attributes that allow the pointer assignment $fptr=>x$. Such a call to C_F_POINTER has the effect of the pointer assignment $fptr=>x$.

If $x$ is a scalar, the result is determined as if C_PTR were a derived type containing a scalar pointer component PX of the type and type parameters of $x$ and the pointer assignment CPTR%PX=>x were executed.

If $x$ is an array, the result is determined as if C_PTR were a derived type containing a scalar pointer component PX of the type and type parameters of $x$ and the pointer assignment CPTR%PX to the first element of $x$ were executed.

• ISO_C_BINDING Module
• C_F_POINTER
CACHESIZE

Inquiry Intrinsic Function (Generic): Returns the size of a level of the memory cache.

Syntax

result = CACHESIZE (n)

n (Input) Must be scalar and of type integer.

Results

The result type is the same as n. The result value is the number of kilobytes in the level n memory cache.

n = 1 specifies the first level cache; n = 2 specifies the second level cache; etc. If cache level n does not exist, the result value is 0.

Example

CACHESIZE(1) returns 16 for a processor with a 16KB first level memory cache.

CALL

Statement: Transfers control to a subroutine subprogram.

Syntax

CALL sub(( [a-arg[,a-arg]...] ))

sub Is the name of the subroutine subprogram or other external procedure, or a dummy argument associated with a subroutine subprogram or other external procedure.

a-arg Is an actual argument optionally preceded by [keyword=], where keyword is the name of a dummy argument in the explicit interface for the subroutine. The keyword is assigned a value when the procedure is invoked.

Each actual argument must be a variable, an expression, the name of a procedure, or an alternate return specifier. (It must not be the name of an internal procedure, statement function, or the generic name of a procedure.)
An alternate return specifier is an asterisk (*), or ampersand (&) followed by the label of an executable branch target statement in the same scoping unit as the CALL statement. (An alternate return is an obsolescent feature in Fortran 95 and Fortran 90.)

Description
When the CALL statement is executed, any expressions in the actual argument list are evaluated, then control is passed to the first executable statement or construct in the subroutine. When the subroutine finishes executing, control returns to the next executable statement following the CALL statement, or to a statement identified by an alternate return label (if any).

If an argument list appears, each actual argument is associated with the corresponding dummy argument by its position in the argument list or by the name of its keyword. The arguments must agree in type and kind parameters.

If positional arguments and argument keywords are specified, the argument keywords must appear last in the actual argument list.

If a dummy argument is optional, the actual argument can be omitted.

An actual argument associated with a dummy procedure must be the specific name of a procedure, or be another dummy procedure. Certain specific intrinsic function names must not be used as actual arguments (see Functions Not Allowed as Actual Arguments).

The procedure invoked by the CALL statement must be a subroutine subprogram and not a function. Calling a function as if it were a subroutine can cause unpredictable results.

Example
The following example shows valid CALL statements:

CALL CURVE(BASE, 3.14159+X, Y, LIMIT, R(LT+2))
CALL PNTOUT(A, N, 'ABCD')
CALL EXIT
CALL MULT(A, B, *10, *20, C)  ! The asterisks and ampersands denote alternate returns
CALL SUBA(X, &30, &50, Y)  ! alternate returns
The following example shows a subroutine with argument keywords:

```fortran
PROGRAM KEYWORD_EXAMPLE

    INTERFACE
        SUBROUTINE TEST_C(I, L, J, KYWD2, D, F, KYWD1)
            INTEGER I, L(20), J, KYWD1
            REAL, OPTIONAL :: D, F
            COMPLEX KYWD2
        ...
        END SUBROUTINE TEST_C
    END INTERFACE

    INTEGER I, J, K
    INTEGER L(20)
    COMPLEX Z1
    CALL TEST_C(I, L, J, KYWD1 = K, KYWD2 = Z1)
    ...

The first three actual arguments are associated with their corresponding dummy arguments by position. The argument keywords are associated by keyword name, so they can appear in any order.

Note that the interface to subroutine TEST has two optional arguments that have been omitted in the CALL statement.

The following shows another example of a subroutine call with argument keywords:

```fortran
CALL TEST(X, Y, N, EQUALITIES = Q, XSTART = X0)
```

The first three arguments are associated by position.
The following shows another example:

! Variations on a subroutine call

```fortran
REAL S,T,X
INTRINSIC NINT
S=1.5
T=2.5
X=14.7
! This calls SUB1 using keywords. NINT is an intrinsic function.
CALL SUB1(B=X,C=S*T,FUNC=NINT,A=4.0)

! Here is the same call using an implicit reference
CALL SUB1(4.0,X,S*T,NINT)
```

CONTAINS

```fortran
SUBROUTINE sub1(a,b,c,func)
INTEGER func
REAL a,b,c
PRINT *, a,b,c, func(b)
END SUBROUTINE
```

END

- Program Units and Procedures
CASE

Statement: Marks the beginning of a CASE construct. A CASE construct conditionally executes one block of constructs or statements depending on the value of a scalar expression in a SELECT CASE statement.

Syntax

[\text{name}]\ SELECT CASE (\text{expr})

[CASE (\text{case-value} [, \text{case-value}] ...) [\text{name}]

\text{block}]

[CASE DEFAULT [\text{name}]

\text{block}]

END SELECT [\text{name}]

\text{expr} \ Is a scalar expression of type integer, logical, or character (enclosed in parentheses). Evaluation of this expression results in a value called the case index.

\text{case-value} \ Is one or more scalar integer, logical, or character initialization expressions enclosed in parentheses. Each case-value must be of the same type and kind parameter as expr. If the type is character, case-value and expr can be of different lengths, but their kind parameter must be the same. Integer and character expressions can be expressed as a range of case values, taking one of the following forms:

- \text{low:high}
- \text{low:}
- \text{:high}

Case values must not overlap.

\text{block} \ Is a sequence of zero or more statements or constructs.
**Description**

If a construct name is specified in a SELECT CASE statement, the same name must appear in the corresponding END SELECT statement. The same construct name can optionally appear in any CASE statement in the construct. The same construct name must not be used for different named constructs in the same scoping unit.

The case expression (\( expr \)) is evaluated first. The resulting case index is compared to the case values to find a matching value (there can only be one). When a match occurs, the block following the matching case value is executed and the construct terminates.

The following rules determine whether a match occurs:

- When the case value is a single value (no colon appears), a match occurs as follows:

<table>
<thead>
<tr>
<th><strong>Data Type</strong></th>
<th><strong>A MatchOccurs If:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Logical</td>
<td>case-index .EQV. case-value</td>
</tr>
<tr>
<td>Integer or Character</td>
<td>case-index = = case-value</td>
</tr>
</tbody>
</table>

- When the case value is a range of values (a colon appears), a match depends on the range specified, as follows:

<table>
<thead>
<tr>
<th><strong>Range</strong></th>
<th><strong>A Match Occurs If:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>low : high</td>
<td>case-index &gt;= low</td>
</tr>
<tr>
<td>low : high</td>
<td>case-index &lt;= high</td>
</tr>
<tr>
<td>low : high</td>
<td>low &lt;= case-index &lt;= high</td>
</tr>
</tbody>
</table>

The following are all valid case values:

- `CASE (1, 4, 7, 11:14, 22)` ! Individual values as specified:
  
  - 1, 4, 7, 11, 12, 13, 14, 22
- `CASE (: -1)` ! All values less than zero
- `CASE (0)` ! Only zero
- `CASE (1:)` ! All values above zero

If no match occurs but a CASE DEFAULT statement is present, the block following that statement is executed and the construct terminates.
If no match occurs and no CASE DEFAULT statement is present, no block is executed, the construct terminates, and control passes to the next executable statement or construct following the END SELECT statement.
The following figure shows the flow of control in a **CASE** construct:
Figure 47: Flow of Control in CASE Constructs
You cannot use branching statements to transfer control to a CASE statement. However, branching to a SELECT CASE statement is allowed. Branching to the END SELECT statement is allowed only from within the CASE construct.

Example

The following are examples of CASE constructs:

```fortran
INTEGER FUNCTION STATUS_CODE (I)
   INTEGER I
   CHECK_STATUS: SELECT CASE (I)
   CASE (:-1)
      STATUS_CODE = -1
   CASE (0)
      STATUS_CODE = 0
   CASE (1:)
      STATUS_CODE = 1
   END SELECT CHECK_STATUS
END FUNCTION STATUS_CODE

SELECT CASE (J)
CASE (1, 3:7, 9) ! Values: 1, 3, 4, 5, 6, 7, 9
   CALL SUB_A
CASE DEFAULT
   CALL SUB_B
END SELECT
```
The following three examples are equivalent:

1. SELECT CASE (ITEST .EQ. 1)
   CASE (.TRUE.)
     CALL SUB1 ()
   CASE (.FALSE.)
     CALL SUB2 ()
   END SELECT

2. SELECT CASE (ITEST)
   CASE DEFAULT
     CALL SUB2 ()
   CASE (1)
     CALL SUB1 ()
   END SELECT

3. IF (ITEST .EQ. 1) THEN
   CALL SUB1 ()
ELSE
   CALL SUB2 ()
END IF
The following shows another example:

```fortran
CHARACTER*1 cmdchar
GET_ANSWER: SELECT CASE (cmdchar)
CASE ('0')
   WRITE (*, *) "Must retrieve one to nine files"
CASE ('1':'9')
   CALL RetrieveNumFiles (cmdchar)
CASE ('A', 'a')
   CALL AddEntry
CASE ('D', 'd')
   CALL DeleteEntry
CASE ('H', 'h')
   CALL Help
CASE DEFAULT
   WRITE (*, *) "Command not recognized; please use H for help"
END SELECT GET_ANSWER
```

**CDFLOAT**

*Portability Function:* Converts a COMPLEX(4) argument to double-precision real type.

**Module**

USE IFPORT

**Syntax**

`result = CDFLOAT (input)`

*input* (Input) COMPLEX(4). The value to be converted.
Results
The result type is REAL(8).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

CEILING
Elemental Intrinsic Function (Generic):
Returns the smallest integer greater than or equal to its argument.

Syntax
result = CEILING (a[,kind])

a       (Input) Must be of type real.
kind    (Input; optional) Must be a scalar integer initialization expression. This argument is a Fortran 95 feature.

Results
The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.
The value of the result is equal to the smallest integer greater than or equal to a.
The setting of compiler options specifying integer size can affect this function.

Example
CEILING (4.8) has the value 5.
CEILING (-2.55) has the value -2.0.
The following shows another example:
INTEGER I, IARRAY(2)
I = CEILING(8.01) ! returns 9
I = CEILING(-8.01) ! returns -8
IARRAY = CEILING((/8.01,-5.6/)) ! returns (9, -5)

CHANGEDIRQQ

Portability Function: Makes the specified directory the current, default directory.

Module

USE IFPORT

Syntax

result = CHANGEDIRQQ (dir)

dir (Input) Character*(*) Directory to be made the current directory.

Results

The result type is LOGICAL(4). It is .TRUE. if successful; otherwise, .FALSE..

If you do not specify a drive in the dir string, the named directory on the current drive becomes the current directory. If you specify a drive in dir, the named directory on the specified drive becomes the current directory.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT

LOGICAL(4) status

status = CHANGEDIRQQ('d:\fps90\bin\bessel')

See Also

- C to D

- CHANGEDRIVEQQ
CHANGEDRIVEQQ

Portability Function: Makes the specified drive the current, default drive.

Module
USE IFPORT

Syntax
result = CHANGEDRIVEQQ (drive)
drive (Input) Character*(*). String beginning with the drive letter.

Results
The result type is LOGICAL(4). On Windows* systems, the result is .TRUE. if successful; otherwise, .FALSE. On Linux* and Mac OS* X systems, the result is always .FALSE..

Because drives are identified by a single alphabetic character, CHANGEDRIVEQQ examines only the first character of drive. The drive letter can be uppercase or lowercase.

CHANGEDRIVEQQ changes only the current drive. The current directory on the specified drive becomes the new current directory. If no current directory has been established on that drive, the root directory of the specified drive becomes the new current directory.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
LOGICAL(4) status
status = CHANGEDRIVEQQ('d')

• GETDRIVESIZEQQ
• GETDRIVEDIRQQ
• CHANGEDIRQQ
CHAR

**Elemental Intrinsic Function (Generic):**
Returns the character in the specified position of the processor’s character set. It is the inverse of the function ICHAR.

**Syntax**

\[
\text{result} = \text{CHAR} (i[,kind])
\]

- **i** (Input) Must be of type integer with a value in the range 0 to \( n - 1 \), where \( n \) is the number of characters in the processor’s character set.
- **kind** (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result is of type character with length 1. If \( \text{kind} \) is present, the kind parameter of the result is that specified by \( \text{kind} \); otherwise, the kind parameter of the result is that of default character. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result is the character in position \( i \) of the processor’s character set. \( \text{ICHAR(CHAR}(i, \text{kind}(c))) \) has the value 1 for 0 to \( n - 1 \) and \( \text{CHAR(ICHAR}(c, \text{kind}(c)) \) has the value \( c \) for any character \( c \) capable of representation in the processor.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (^1)</td>

- IACHAR
- ICHAR
- Character and Key Code Charts

**CHARACTER**

*Statement:* Specifies the CHARACTER data type.

**Syntax**

```
CHARACTER

CHARACTER([KIND=] n)

CHARACTER*len
```

- `n` Is kind 1.
- `len` Is a string length (not a kind). For more information, see Declaration Statements for Character Types. If no kind type parameter is specified, the kind of the constant is default character.
Example

C
C Length of wt and vs is 10, city is 80, and ch is 1
C
CHARACTER wt*10, city*80, ch
CHARACTER (LEN = 10), PRIVATE :: vs
CHARACTER(*) arg !declares a dummy argument
C name and plume are ten-element character arrays
C of length 20
CHARACTER name(10)*20
CHARACTER(len=20), dimension(10):: plume
C
C Length of susan, patty, and dotty are 2, alice is 12,
C jane is a 79-member array of length 2
C
CHARACTER(2) susan, patty, alice*12, dotty, jane(79)

CHDIR
Portability Function: Changes the default directory.

Module
USE IFPORT
Syntax

result = CHDIR(dir_name)

dir_name  (Input) Character*(*) . Name of a directory to become the default directory.

Results

The result type is INTEGER(4). It returns zero if the directory was changed successfully; otherwise, an error code. Possible error codes are:

- ENOENT: The named directory does not exist.
- ENOTDIR: The dir_name parameter is not a directory.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

use ifport
integer(4) istatus, enoent, enotdir
character(255) newdir
character(300) prompt, errmsg
prompt = 'Please enter directory name: '
10 write(*,*) TRIM(prompt)
read *, newdir
ISTATUS = CHDIR(newdir)
select case (istatus)
  case (2) ! ENOENT
    errmsg = 'The directory ' // TRIM(newdir) // ' does not exist'
  case (20) ! ENOTDIR
    errmsg = TRIM(newdir) // ' is not a directory'
  case (0) ! NO error
    goto 40
  case default
    write (errmsg,* ) 'Error with code ', istatus
  end select
write(*,*) TRIM(errmsg)
goto 10
40 write(*,*) 'Default directory successfully changed.'
end

**CHMOD**

*Portability Function: Changes the access mode of a file.*

**Module**

USE IFPORT

**Syntax**

```plaintext
result = CHMOD (name, mode)
```

- **name** *(Input) Character*(*)*. Name of the file whose access mode is to be changed. Must have a single path.
- **mode** *(Input) Character*(*)*. File permission: either Read, Write, or Execute. The mode parameter can be either symbolic or absolute. An absolute mode is specified with an octal number, consisting of any combination of the following permission bits ORed together:

<table>
<thead>
<tr>
<th>Permission bit</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>4000</td>
<td>Set user ID on execution</td>
<td>W<em>32, W</em>64: Ignored; L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>2000</td>
<td>Set group ID on execution</td>
<td>W<em>32, W</em>64: Ignored; L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>1000</td>
<td>Sticky bit</td>
<td>W<em>32, W</em>64: Ignored; L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0400</td>
<td>Read by owner</td>
<td>W<em>32, W</em>64: Ignored; L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0200</td>
<td>Write by owner</td>
<td>Settable</td>
</tr>
<tr>
<td>Permission bit</td>
<td>Description</td>
<td>Action</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>0100</td>
<td>Execute by owner</td>
<td>W<em>32, W</em>64: Ignored; based on file name extension L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0040, 0020, 0010</td>
<td>Read, Write, Execute by group</td>
<td>W<em>32, W</em>64: Ignored; assumes owner permissions L<em>X, M</em>X: Settable</td>
</tr>
<tr>
<td>0004, 0002, 0001</td>
<td>Read, Write, Execute by others</td>
<td>W<em>32, W</em>64: Ignored; assumes owner permissions L<em>X, M</em>X: Settable</td>
</tr>
</tbody>
</table>

The following regular expression represents a symbolic mode:

```
[ugoa]*[-+]= [rwxXst]*
```

"[ugoa]*" is ignored on Windows* systems. On Linux* and Mac OS* X systems, a combination of the letters "ugoa" control which users' access to the file will be changed:

- **u**: The user who owns the file
- **g**: Other users in the group that owns the file
- **o**: Other users not in the group that owns the file
- **a**: All users

"[+-=]" indicates the operation to carry out:

- **+**: Add the permission
- **-**: Remove the permission
- **=**: Absolutely set the permission
"[rwxXst]*" indicates the permission to add, subtract, or set. On Windows systems, only "w" is significant and affects write permission; all other letters are ignored. On Linux and Mac OS X systems, all letters are significant.

**Results**

The result type is INTEGER(4). It is zero if the mode was changed successfully; otherwise, an error code. Possible error codes are:

- **ENOENT**: The specified file was not found.
- **EINVAL**: The mode argument is invalid.
- **EPERM**: Permission denied; the file's mode cannot be changed.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
USE IFPORT
integer(4) I, Istatus
I = ACCESS ("DATAFILE.TXT", "w")
if (i) then
   ISTATUS = CHMOD ("datafile.txt", "+w")
end if
I = ACCESS ("DATAFILE.TXT","w")
print *, i
```

**CLEARSCREEN (W*32, W*64)**

*Graphics Subroutine: Erases the target area and fills it with the current background color.*

**Module**

USE IFQWIN
Syntax

CALL CLEARSCREEN (area)

area (Input) INTEGER(4). Identifies the target area. Must be one of the following symbolic constants (defined in IFQWIN.F90):

- $GCLEARSCREEN - Clears the entire screen.
- $GVIEWPORT - Clears only the current viewport.
- $GWINDOW - Clears only the current text window (set with SETTEXTWINDOW).

All pixels in the target area are set to the color specified with SETBKCOLORRGB. The default color is black.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example

USE IFQWIN
CALL CLEARSCREEN($GCLEARSCREEN)

Building Applications: Real Coordinates Sample Program

CLEARSTATUSFPQQ

Portability Subroutine: Clears the exception flags in the floating-point processor status word.

Module

USE IFPORT
Syntax

CALL CLEARSTATUSFPQQ()

Description

The floating-point status word indicates which floating-point exception conditions have occurred. Intel® Fortran initially clears (sets to 0) all floating-point status flags, but as exceptions occur, the status flags accumulate until the program clears the flags again. CLEARSTATUSFPQQ will clear the flags.

CLEARSTATUSFPQQ is appropriate for use in applications that poll the floating-point status register as the method for detecting a floating-point exception has occurred.

For a full description of the floating-point status word, exceptions, and error handling, see Floating-Point Operations: Floating-Point Environment.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
Example

! Program to demonstrate CLEARSTATUSFPQQ.
! This program uses polling to detect that a
! floating-point exception has occurred.
! So, build this console application with the default
! floating-point exception behavior, fpe3.
! You need to specify compiler option /debug or /Od (Windows)
! or -O0 (Linux) to get the correct results
! PROGRAM CLEARFP
  USE IFPORT
  REAL*4 A,B,C
  INTEGER*2 STS
  A = 2.0E0
  B = 0.0E0
! Poll and display initial floating point status
  CALL GETSTATUSFPQQ(STS)
  WRITE(*,'(1X,A,Z4.4)') 'Initial fp status = ',STS
! Cause a divide-by-zero exception
! Poll and display the new floating point status
  C = A/B
  CALL GETSTATUSFPQQ(STS)
  WRITE(*,'(1X,A,Z4.4)') 'After div-by-zero fp status = ',STS
! If a divide by zero error occurred, clear the floating point
! status register so future exceptions can be detected.
IF ((STS .AND. FPSW$ZERODIVIDE) > 0) THEN
  CALL CLEARSTATUSFPQQ()
  CALL GETSTATUSFPQQ(STS)
  WRITE(*,'(1X,A,Z4.4)') 'After CLEARSTATUSFPQQ fp status = ',STS
This program is available in the online samples.

**CLICKMENUQQ (W*32, W*64)**

*QuickWin Function:* Simulates the effect of clicking or selecting a menu command. The QuickWin application responds as though the user had clicked or selected the command.

**Module**

```
USE IFQWIN
```

**Syntax**

```
result = CLICKMENUQQ (item)
```

- **item** (Input) INTEGER(4). Constant that represents the command selected from the Window menu. Must be one of the following symbolic constants (defined in IFQWIN.F90):
  - `QWIN$STATUS` - Status command
  - `QWIN$TILE` - Tile command
  - `QWIN$CASCADE` - Cascade command
  - `QWIN$ARRANGE` - Arrange Icons command

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

**Portability Subroutine:** Returns the processor clock to the nearest microsecond.

**Module**

USE IFPORT

**Syntax**

CALL CLOCKX (clock)

\( \text{clock} \quad \text{(Input) REAL(8). The current time.} \)

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

CLOSE

**Statement:** Disconnects a file from a unit.

**Syntax**

\( \text{io-unit} \quad \text{(Input) an external unit specifier.} \)

\( p \quad \text{(Input) a scalar default character expression indicating the status of the file after it is closed. It has one of the following values:} \)

- 'KEEP' or 'SAVE' - Retains the file after the unit closes.
- 'DELETE' - Deletes the file after the unit closes (unless OPEN(READONLY) is in effect).
- 'PRINT' - Submits the file to the line print spooler, then retains it (sequential files only).
- 'PRINT/DELETE' - Submits the file to the line print spooler, then deletes it (sequential files only).
- 'SUBMIT' - Forks a process to execute the file.
• 'SUBMIT/DELETE' - Forks a process to execute the file, then deletes the file after the fork is completed.

The default is 'DELETE' for QuickWin applications (W*32, W*64) and for scratch files. For all other files, the default is 'KEEP'. Scratch files are temporary and are always deleted upon normal program termination; specifying STATUS='KEEP' for scratch files causes a run-time error.

For Windows* QuickWin applications, STATUS='KEEP' causes the child window to remain on the screen even after the unit closes. The default status is 'DELETE', which removes the child window from the screen.

\begin{tabular}{ll}
\textit{label} & Is the label of the branch target statement that receives control if an error occurs. \\
\textit{i-var} & (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs. \\
\end{tabular}

\textbf{Description}

The CLOSE statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

The status specified in the CLOSE statement supersedes the status specified in the OPEN statement, except that a file opened as a scratch file cannot be saved, printed, or submitted, and a file opened for read-only access cannot be deleted.

If a CLOSE statement is specified for a unit that is not open, it has no effect.

You do not need to explicitly close open files. Normal program termination closes each file according to its default status. The CLOSE statement does not have to appear in the same program unit that opened the file.

Closing unit 0 automatically reconnects unit 0 to the keyboard and screen. Closing units 5 and 6 automatically reconnects those units to the keyboard or screen, respectively. Closing the asterisk (*) unit causes a compile-time error. In Windows QuickWin applications, use CLOSE with unit 0, 5, or 6 to close the default window. If all of these units have been detached from the console (through an explicit OPEN), you must close one of these units beforehand to reestablish its connection with the console. You can then close the reconnect unit to close the default window.

If a parameter of the CLOSE statement is an expression that calls a function, that function must not cause an I/O operation or the EOF intrinsic function to be executed, because the results are unpredictable.
Example

C   Close and discard file:

    CLOSE (?, STATUS = 'DELETE')

Consider the following statement:

    CLOSE (UNIT=J, STATUS='DELETE', ERR=99)

This statement closes the file connected to unit J and deletes it. If an error occurs, control is transferred to the statement labeled 99.

CMPLX

Elemental Intrinsic Function (Specific):

Converts the argument to complex type. This function cannot be passed as an actual argument.

Syntax

\[ \text{result} = \text{CMPLX} (x[,y [,\text{kind}])] \]

- \( x \) (Input) Must be of type integer, real, or complex.
- \( y \) (Input; optional) Must be of type integer or real. It must not be present if \( x \) is of type complex.
- \( \text{kind} \) (Input; optional) Must be a scalar integer initialization expression.

Results

The result type is complex. If \( \text{kind} \) is present, the kind parameter is that specified by \( \text{kind} \); otherwise, the kind parameter is that of default real type.

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If \( y \) is not specified and \( x \) is complex, the result value is CMPLX(REAL( \( x \)), AIMAG( \( x \))).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.
CMPLX( x, y, kind) has the complex value whose real part is REAL( x, kind) and whose imaginary part is REAL( y, kind).

The setting of compiler options specifying real size can affect this function.

Example
CMPLX(-3) has the value (-3.0, 0.0).
CMPLX(4.1, 2.3) has the value (4.1, 2.3).

The following shows another example:

```fortran
COMPLEX z1, z2
COMPLEX(8) z3
z1 = CMPLX(3) ! returns the value 3.0 + i 0.0
z2 = CMPLX(3,4) ! returns the value 3.0 + i 4.0
z3 = CMPLX(3,4,8) ! returns a COMPLEX(8) value 3.0D0 + i 4.0D0
```

COMAddObjectReference (W*32, W*64)
**COM Function:** Adds a reference to an object's interface.

Module
USE IFCOM

Syntax
```fortran
result = COMAddObjectReference (iunknown)
```

`iunknown` An IUnKnown interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
**Results**
The result type is INTEGER(4). It is the object's current reference count.

- C to D

IUnknown::AddRef in the Microsoft* Platform SDK

**COMCLSIDFromProgID (W*32, W*64)**

**COM Subroutine:** Passes a programmatic identifier and returns the corresponding class identifier.

**Module**
USE IFCOM
USE IFWINTY

**Syntax**
CALL COMCLSIDFromProgID (prog_id, clsid, status)

- **prog_id**
  The programmatic identifier of type CHARACTER(*).

- **clsid**
  The class identifier corresponding to the programmatic identifier. Must be of type GUID, which is defined in the IFWINTY module.

- **status**
  The status of the operation. It can be any status returned by CLSIDFromProgID. Must be of type INTEGER(4).

**See Also**
- C to D

CLSIDFromProgID in the Microsoft* Platform SDK

**COMCLSIDFromString (W*32, W*64)**

**COM Subroutine:** Passes a class identifier string and returns the corresponding class identifier.

**Module**
USE IFCOM
USE IFWINTY
Syntax

CALL COMCLSIDFromString (string, clsid, status)

string    The class identifier string of type CHARACTER*(*).
clsid     The class identifier corresponding to the identifier string. Must be of type GUID, which is defined in the IFWINTY module.
status    The status of the operation. It can be any status returned by CLSIDFromString. Must be of type INTEGER(4).

See Also

• C to D

CLSIDFromString in the Microsoft* Platform SDK

**COMCreateObjectByGUID (W*32, W*64)**

**COM Subroutine:** Passes a class identifier, creates an instance of an object, and returns a pointer to the object's interface.

Module

USE IFCOM
USE IFWINTY

Syntax

CALL COMCreateObjectByGUID (clsid, clsctx, iid, interface, status)

clsid     The class identifier of the class of object to be created. Must be of type GUID, which is defined in the IFWINTY module.
clsctx    Lets you restrict the types of servers used for the object. Must be of type INTEGER(4). Must be one of the CLSCTX_* constants defined in the IFWINTY module.
iid       The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.
interface An output argument that returns the object's interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
status    The status of the operation. It can be any status returned by CoCreateInstance. Must be of type INTEGER(4).

*Building Applications*: Getting a Pointer to an Object's Interface

**COMGetActiveObjectByGUID (W*32, W*64)**

*COM Subroutine*: Passes a class identifier and returns a pointer to the interface of a currently active object.

**Module**

USE IFCOM
USE IFWINTY

Syntax
CALL COMGetActiveObjectByGUID (clsid, iid, interface, status)

.clsid  The class identifier of the class of object to be found. Must be of type GUID, which is defined in the IFWINTY module.
.iid  The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.
.interface  An output argument that returns the object’s interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
.status  The status of the operation. It can be any status returned by GetActiveObject. Must be of type INTEGER(4).

See Also
•  C to D
GetActiveObject in the Microsoft* Platform SDK

COMGetActiveObjectByProgID (W*32, W*64)

COM Subroutine: Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object.

Module
USE IFCOM

Syntax
CALL COMGetActiveObjectByProgID (prog_id, idispatch, status)

.prog_id  The programmatic identifier of type CHARACTER*(*).
.idispatch  An output argument that returns the object’s IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
.status  The status of the operation. It can be any status returned by CLSIDFromProgID or GetActiveObject. Must be of type INTEGER(4).

Example
See the example in COMInitialize.

COMGetFileObject (W*32, W*64)

**COM Subroutine:** Passes a file name and returns a pointer to the IDispatch interface of an automation object that can manipulate the file.

Module
USE IFCOM

Syntax
CALL COMGetFileObject (filename, idispatch, status)

- `filename`: The path of the file of type CHARACTER*(*).
- `idispatch`: An output argument that returns the object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
- `status`: The status of the operation. It can be any status returned by the CreateBindCtx or MkParseDisplayName routines, or the IMoniker::BindToObject method. Must be of type INTEGER(4).

See Also

• C to D

CreateBindCtx, MkParseDisplayName, and IMoniker::BindToObject in the Microsoft® Platform SDK

COMInitialize (W*32, W*64)

**COM Subroutine:** Initializes the COM library.

Module
USE IFCOM

Syntax
CALL COMInitialize (status)
The status of the operation. It can be any status returned by OleInitialize. Must be of type INTEGER(4).

You must use this routine to initialize the COM library before calling any other COM or AUTO routine.
Example

Consider the following:

```fortran
program COMExample
use ifwin
use ifcom
use ifauto
    implicit none
    ! Variables
    integer(4) word_app
    integer(4) status
    integer(INT_PTR_KIND()) invoke_args
    call COMInitialize(status)
    ! Call GetActiveObject to get a reference to a running MS WORD application
    call COMGetActiveObjectByProgID("Word.Application", word_app, status)
    if (status >= 0) then
        ! Print the active document
        invoke_args = AutoAllocateInvokeArgs()
        call AutoAddArg(invoke_args, "Copies", 2)
        status = AutoInvoke(word_app, "PrintOut", invoke_args)
        call AutoDeallocateInvokeArgs(invoke_args)
        ! Release the reference
        status = COMReleaseObject(word_app)
    end if
    call COMUninitialize()
end program
```

See Also

- C to D
- OleInitialize in the Microsoft* Platform SDK
COMIsEqualGUID (W*32, W*64)

**COM Function**: Determines whether two globally unique identifiers (GUIDs) are the same.

**Module**

USE IFCOM
USE IFWINTY

**Syntax**

```fortran
result = COMIsEqualGUID (guid1, guid2)
```

**guid1**

The first GUID. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).

**guid2**

The second GUID, which will be compared to `guid1`. It must be the same type of GUID as `guid1`. For example, if `guid1` is a CLSID, `guid2` must also be a CLSID.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if the two GUIDs are the same; otherwise, .FALSE.

**See Also**

- C to D
  - IsEqualGUID in the Microsoft® Platform SDK

**COMMAND_ARGUMENT_COUNT**

*Inquiry Intrinsic Function (Generic)*: Returns the number of command arguments.

**Syntax**

```fortran
result = COMMAND_ARGUMENT_COUNT ()
```
Results

The result is a scalar of type default integer. The result value is equal to the number of command arguments available. If there are no command arguments available, the result is 0. The command name does not count as one of the command arguments.
Example

Consider the following:

```fortran
program echo_command_line
integer i, cnt, len, status
character c*30, b*100

call get_command (b, len, status)
if (status .ne. 0) then
    write (*,*) 'get_command failed with status = ', status
    stop
end if
write (*,*) 'command line = ', b (1:len)

call get_command_argument (0, c, len, status)
if (status .ne. 0) then
    write (*,*) 'Getting command name failed with status = ', status
    stop
end if
write (*,*) 'command name = ', c (1:len)

cnt = command_argument_count ()
write (*,*) 'number of command arguments = ', cnt

do i = 1, cnt
    call get_command_argument (i, c, len, status)
    if (status .ne. 0) then
        write (*,*) 'get_command_argument failed: status = ', status, ' arg = ', i
        stop
    end if
    write (*,*) 'command arg ', i, ' = ', c (1:len)
end do
write (*,*) 'command line processed'
```

Intel® Fortran Compiler User and Reference Guides
If the above program is invoked with the command line "echo_command_line.exe -o 42 -a hello b", the following is displayed:

command line = echo_command_line.exe -o 42 -a hello b
command name = echo_command_line.exe
number of command arguments = 5
command arg 1 = -o
command arg 2 = 42
command arg 3 = -a
command arg 4 = hello
command arg 5 = b
command line processed

**COMMITQQ**

*Run-Time Function:* Forces the operating system to execute any pending write operations for the file associated with a specified unit to the file's physical device.

**Module**

USE IFCORE

**Syntax**

```plaintext
result = COMMITQQ (unit)
```
unit (Input) INTEGER(4). A Fortran logical unit attached to a file to be flushed from cache memory to a physical device.

Results
The result type is LOGICAL(4). If an open unit number is supplied, .TRUE. is returned and uncommitted records (if any) are written. If an unopened unit number is supplied, .FALSE. is returned.

Data written to files on physical devices is often initially written into operating-system buffers and then written to the device when the operating system is ready. Data in the buffer is automatically flushed to disk when the file is closed. However, if the program or the computer crashes before the data is transferred from buffers, the data can be lost. COMMITQQ tells the operating system to write any cached data intended for a file on a physical device to that device immediately. This is called flushing the file.

COMMITQQ is most useful when you want to be certain that no loss of data occurs at a critical point in your program; for example, after a long calculation has concluded and you have written the results to a file, or after the user has entered a group of data items, or if you are on a network with more than one program sharing the same file. Flushing a file to disk provides the benefits of closing and reopening the file without the delay.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFCHNE

INTEGER unit / 10 /
INTEGER len
CHARACTER(80) stuff

OPEN(unit, FILE='COMMITQQ.TST', ACCESS='Sequential')

DO WHILE (.TRUE.)
   WRITE (*, '(A, ', 'Enter some data (Hit RETURN to &
   exit): ')
   len = GETSTRQQ (stuff)
   IF (len .EQ. 0) EXIT
   WRITE (unit, *) stuff
   IF (.NOT. COMMITQQ(unit)) WRITE (*,*) 'Failed'
END DO
CLOSE (unit)

END

COMMON

Statement: Defines one or more contiguous areas, or blocks, of physical storage (called common blocks) that can be accessed by any of the scoping units in an executable program. COMMON statements also define the order in which variables and arrays are stored in each common block, which can prevent misaligned data items.

Syntax

Common blocks can be named or unnamed (a blank common).
COMMON [ /[cname]/ ] var-list[[,] /[/cname]/ var-list]...

cname (Optional) Is the name of the common block. The name can be omitted for blank common (/).

var-list Is a list of variable names, separated by commas. The variable must not be a dummy argument, allocatable array, automatic object, function, function result, a variable with the BIND attribute, or entry to a procedure. It must not have the PARAMETER attribute. If an object of derived type is specified, it must be a sequence type or a type with the BIND attribute.

Description

A common block is a global entity, and must not have the same name as any other global entity in the program, such as a subroutine or function.

Any common block name (or blank common) can appear more than once in one or more COMMON statements in a program unit. The list following each successive appearance of the same common block name is treated as a continuation of the list for the block associated with that name. Consider the following COMMON statements:

COMMON /ralph/ ed, norton, trixie
COMMON / / fred, ethel, lucy
COMMON /ralph/ audrey, meadows
COMMON /jerry/ mortimer, tom, mickey
COMMON melvin, purvis

They are equivalent to these COMMON statements:

COMMON /ralph/ ed, norton, trixie, audrey, meadows
COMMON fred, ethel, lucy, melvin, purvis
COMMON /jerry/ mortimer, tom, mickey

A variable can appear in only one common block within a scoping unit.

If an array is specified, it can be followed by an explicit-shape array specification, each bound of which must be a constant specification expression. Such an array must not have the POINTER attribute.

A pointer can only be associated with pointers of the same type and kind parameters, and rank. An object with the TARGET attribute can only be associated with another object with the TARGET attribute and the same type and kind parameters.
A nonpointer can only be associated with another nonpointer, but association depends on their types, as follows:

<table>
<thead>
<tr>
<th>Type of Variable</th>
<th>Type of Associated Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intrinsic numeric ¹ or numeric sequence ²</td>
<td>Can be of any of these types</td>
</tr>
<tr>
<td>Default character or character sequence ²</td>
<td>Can be of either of these types</td>
</tr>
<tr>
<td>Any other intrinsic type</td>
<td>Must have the same type and kind parameters</td>
</tr>
<tr>
<td>Any other sequence type</td>
<td>Must have the same type</td>
</tr>
</tbody>
</table>

¹Default integer, default real, double precision real, default complex, double complex, or default logical.

²If an object of numeric sequence or character sequence type appears in a common block, it is as if the individual components were enumerated directly in the common list.

So, variables can be associated if they are of different numeric type. For example, the following is valid:

```plaintext
INTEGER A(20)
REAL Y(20)
COMMON /QUANTA/ A, Y
```

When common blocks from different program units have the same name, they share the same storage area when the units are combined into an executable program.

Entities are assigned storage in common blocks on a one-for-one basis. So, the data type of entities assigned by a COMMON statement in one program unit should agree with the data type of entities placed in a common block by another program unit. For example:

<table>
<thead>
<tr>
<th>Program Unit A</th>
<th>Program Unit B</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON CENTS</td>
<td>INTEGER(2) MONEY</td>
</tr>
<tr>
<td></td>
<td>COMMON MONEY</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
When these program units are combined into an executable program, incorrect results can occur if the 2-byte integer variable MONEY is made to correspond to the lower-addressed two bytes of the real variable CENTS.

Named common blocks must be declared to have the same size in each program unit. Blank common can have different lengths in different program units.

**NOTE.** If a common block is initialized by a DATA statement, the module containing the initialization must declare the common block to be its maximum defined length.

This limitation does not apply if you compile all source modules together.

**Example**

PROGRAM MyProg
COMMON i, j, x, k(10)
COMMON /mycom/ a(3)
...
END

SUBROUTINE MySub
COMMON pe, mn, z, idum(10)
COMMON /mycom/ a(3)
...
END

In the following example, the COMMON statement in the main program puts HEAT and X in blank common, and KILO and Q in a named common block, BLK1:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON HEAT,X /BLK1/KILO,Q</td>
<td>SUBROUTINE FIGURE</td>
</tr>
<tr>
<td>...</td>
<td>COMMON /BLK1/LIMA,R / /ALFA,BET</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>CALL FIGURE</td>
<td></td>
</tr>
</tbody>
</table>
The COMMON statement in the subroutine makes ALFA and BET share the same storage location as HEAT and X in blank common. It makes LIMA and R share the same storage location as KILO and Q in BLK1.

The following example shows how a COMMON statement can be used to declare arrays:

```fortran
COMMON / MIXED / SPOTTED(100), STRIPED(50,50)
```

The following example shows a valid association between subroutines in different program units. The object lists agree in number, type, and kind of data objects:

```fortran
SUBROUTINE unit1
REAL(8) x(5)
INTEGER J
CHARACTER str*12
TYPE(member) club(50)
COMMON / blocka / x, j, str, club
...
SUBROUTINE unit2
REAL(8) z(5)
INTEGER m
CHARACTER chr*12
TYPE(member) myclub(50)
COMMON / blocka / z, m, chr, myclub
...
```

See also the example for BLOCK DATA.

**COMPLEX Statement**

**Statement:** Specifies the COMPLEX data type.

**Syntax**

```
COMPLEX

COMPLEX([KIND=] n)

COMPLEX*s

DOUBLE COMPLEX
```

- `n` Is kind 4, 8, or 16.
- `s` Is 8, 16, or 32. COMPLEX(4) is specified as COMPLEX*8; COMPLEX(8) is specified as COMPLEX*16; COMPLEX(16) is specified as COMPLEX*32.

If a kind parameter is specified, the complex constant has the kind specified. If no kind parameter is specified, the kind of both parts is default real, and the constant is of type default complex. **DOUBLE COMPLEX** is COMPLEX(8). No kind parameter is permitted for data declared with type **DOUBLE COMPLEX**.

**Example**

```
COMPLEX ch

COMPLEX (KIND=4),PRIVATE :: zz, yy   !equivalent to COMPLEX*8 zz, yy

COMPLEX(8) ax, by                 !equivalent to COMPLEX*16 ax, by

COMPLEX (kind(4)) y(10)

complex (kind=8) x, z(10)
```

**COMPLINT, COMPREAL, COMPLLOG**

*Portability Functions:* Return a **BIT-WISE** complement or logical .NOT. of the argument.

**Module**

USE IFPORT

**Syntax**

result = COMPLINT (intval)

result = COMPREAL (realval)

result = COMPLLOG (logval)

**Results**

The result is INTEGER(4) for COMPLINT, REAL(4) for COMPREAL and LOGICAL(4) for COMPLLOG with a value that is the bitwise complement of the argument.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**COMQueryInterface (**W*32, W*64)**

*COM Subroutine:* Passes an interface identifier and returns a pointer to an object's interface.

**Module**

USE IFCOM

USE IFWINTY
Syntax

CALL COMQueryInterface (iunknown, iid, interface, status)

iunknown  An IUnknown interface pointer. Must be of type INTEGER(4).
iid       The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.
interface  An output argument that returns the object’s interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
status     The status of the operation. It can be any status returned by the IUnknown method QueryInterface. Must be of type INTEGER(4).

See Also

•  C to D

IUnknown::QueryInterface in the Microsoft* Platform SDK

Building Applications: Getting a Pointer to an Object’s Interface

COMReleaseObject (W*32, W*64)

COM Function: Indicates that the program is done with a reference to an object’s interface.

Module

USE IFCOM

Syntax

result = COMReleaseObject (iunknown)

iunknown  An IUnknown interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

Results

The result type is INTEGER(4). It is the object’s current reference count.

Example

See the example in COMInitialize.
**COMStringFromGUID (W*32, W*64)**

**COM Subroutine:** Passes a globally unique identifier (GUID) and returns a string of printable characters.

**Module**

USE IFCOM

USE IFWINTY

**Syntax**

CALL COMStringFromGUID (guid, string, status)

- **guid**
  The GUID to be converted. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).

- **string**
  A character variable of type CHARACTER(*) that receives the string representation of the GUID. The length of the character variable should be at least 38.

- **status**
  The status of the operation. If the string is too small to contain the string representation of the GUID, the value is zero. Otherwise, the value is the number of characters in the string representation of the GUID. Must be of type INTEGER(4).

The string representation of a GUID has a format like that of the following:

[c200e360-38c5-11ce-ae62-08002b2b79ef]

where the successive fields break the GUID into the form DWORD-WORD-WORD-WORD-WORD.DWORD covering the 128-bit GUID. The string includes enclosing braces, which are an OLE convention.

**See Also**

- C to D

StringFromGUID2 in the Microsoft* Platform SDK
COMUninitialize (W*32, W*64)

**COM Subroutine:** Uninitializes the COM library.

**Module**

USE IFCOM

**Syntax**

CALL COMUninitialize()

When using COM routines, this must be the last routine called.

**Example**

See the example in COMInitialize.

---

**CONJG**

*Elemental Intrinsic Function (Generic):*

Calculates the conjugate of a complex number.

**Syntax**

\[
\text{result} = \text{CONJG}(z)
\]

\[z\] (Input) Must be of type complex.

**Results**

The result type is the same as \(z\). If \(z\) has the value \((x, y)\), the result has the value \((x, -y)\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONJG</td>
<td>COMPLEX(4)</td>
<td>COMPLEX(4)</td>
</tr>
<tr>
<td>DCONJG</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>QCONJG</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

**Example**

CONJG \(((2.0, 3.0))\) has the value \((2.0, -3.0)\).

CONJG \(((1.0, -4.2))\) has the value \((1.0, 4.2)\).
The following shows another example:

```fortran
COMPLEX z1
COMPLEX(8) z2
z1 = CONJG((3.0, 5.6)) ! returns (3.0, -5.6)
z2 = DCONJG((3.0D0, 5.6D0)) ! returns (3.0D0, -5.6D0)
```

**See Also**
- C to D
- AIMAG

**CONTAINS**

**Statement:** Separates the body of a main program, module, or external subprogram from any internal or module procedures it may contain. It is not executable.

**Syntax**

```fortran
CONTAINS
```

Any number of internal procedures can follow a CONTAINS statement, but a CONTAINS statement cannot appear in the internal procedures themselves.

**Example**

```fortran
PROGRAM OUTER
    REAL, DIMENSION(10) :: A
    ...
    CALL INNER (A)
    CONTAINS
    SUBROUTINE INNER (B)
    REAL, DIMENSION(10) :: B
    ...
    END SUBROUTINE INNER
END PROGRAM OUTER
```
See Also
• C to D
• Internal Procedures
• Modules and Module Procedures
• Main Program

CONTINUE
Statement: Primarily used to terminate a labeled DO construct when the construct would otherwise end improperly with either a GO TO, arithmetic IF, or other prohibited control statement.

Syntax
CONTINUE

The statement by itself does nothing and has no effect on program results or execution sequence.

Example
The following example shows a CONTINUE statement:

```
DO 150 I = 1,40
40  Y = Y + 1
   Z = COS(Y)
   PRINT *, Z
   IF (Y .LT. 30) GO TO 150
   GO TO 40
150 CONTINUE
```

The following shows another example:

```
DIMENSION narray(10)
DO 100 n = 1, 10
   narray(n) = 120
100 CONTINUE
```

See Also
• C to D
• END DO
• DO
• Execution Control

**COPYIN**

*Parallel Directive Clause: Specifies that the data in the master thread of the team is to be copied to the thread private copies of the common block at the beginning of the parallel region.*

**Syntax**

```
COPYIN (list)
```

*list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

The COPYIN clause applies only to common blocks declared as THREADPRIVATE.

You do not need to specify the whole THREADPRIVATE common block, you can specify named variables within the common block.

**COPYPRIVATE**

*Parallel Directive Clause: Uses a private variable to broadcast a value, or a pointer to a shared object, from one member of a team to the other members. The COPYPRIVATE clause can only appear in the END SINGLE directive.*

**Syntax**

```
COPYPRIVATE (list)
```

*list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables in the list must not appear in a PRIVATE or FIRSTPRIVATE clause for the SINGLE directive construct.
If the directive is encountered in the dynamic extent of a parallel region, variables in the list must be private in the enclosing context.

If a common block is specified, it must be declared as THREADPRIVATE; the effect is the same as if the variable names in its common block object list were specified.

The effect of the COPYPRIVATE clause on the variables in its list occurs after the execution of the code enclosed within the SINGLE construct, and before any threads in the team have left the barrier at the end of the construct.

COS

*Elemental Intrinsic Function (Generic):*

*Produces the cosine of x.*

**Syntax**

```fortran
result = COS (x)
```

`x` (Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*pi. If `x` is of type complex, its real part is regarded as a value in radians.

**Results**

The result type is the same as `x`.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COS</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>Dcos</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOS</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
<tr>
<td>CCOS</td>
<td>COMPLEX(4)</td>
<td>COMPLEX(4)</td>
</tr>
<tr>
<td>CDCOS</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQCOS</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

1 The setting of compiler options specifying real size can affect CCOS.

2 This function can also be specified as ZCOS.
Example

COS (2.0) has the value -0.4161468.
COS (0.567745) has the value 0.8431157.

• C to D

*Optimizing Applications*: Types of Vectorized Loops

**COSD**

*Elemental Intrinsic Function (Generic):* Produces the cosine of \( x \).

**Syntax**

\[
\text{result} = \text{COSD} (x)
\]

\( x \) (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type is the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COSD</td>
<td>REAL(4)</td>
<td>REAL(4)</td>

<tr>
<td>DCOSD</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOSD</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COSD (2.0) has the value 0.9993908.
COSD (30.4) has the value 0.8625137.
COSH

Elemental Intrinsic Function (Generic):
Produces a hyperbolic cosine.

Syntax
result = COSH (x)
x
(Input) Must be of type real.

Results
The result type is the same as x.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COSH</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DCOSH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOSH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example
COSH (2.0) has the value 3.762196.
COSH (0.65893) has the value 1.225064.

COTAN

Elemental Intrinsic Function (Generic):
Produces the cotangent of x.

Syntax
result = COTAN (x)
x
(Input) Must be of type real; it cannot be zero. It must be in radians and is treated as modulo 2*pi.

Results
The result type is the same as x.
<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COTAN</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DCOTAN</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOTAN</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COTAN (2.0) has the value -4.576575E-01.

COTAN (0.6) has the value 1.461696.

**COTAND**

*Elemental Intrinsic Function (Generic):* Produces the cotangent of \( x \).

**Syntax**

\[
\text{result} = \text{COTAND} (x)
\]

\( x \) (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type is the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COTAND</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DCOTAND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOTAND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COTAND (2.0) has the value 0.2863625E+02.

COTAND (0.6) has the value 0.9548947E+02.
COUNT

Transformational Intrinsic Function (Generic):
Counts the number of true elements in an entire array or in a specified dimension of an array.

Syntax

result = COUNT (mask[,dim][, kind])

- mask (Input) Must be a logical array.
- dim (Input; optional) Must be a scalar integer expression with a value in the range 1 to n, where n is the rank of mask.
- kind (Input; optional) Must be a scalar integer initialization expression.

Results

The result is an array or a scalar of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result is a scalar if dim is omitted or mask has rank one. A scalar result has a value equal to the number of true elements of mask. If mask has size zero, the result is zero.

An array result has a rank that is one less than mask, and shape (d_1, d_2, ..., d_dim-1, d_dim+1, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of mask.

Each element in an array result equals the number of elements that are true in the one dimensional array defined by mask(s_1, s_2, ..., s_dim-1, :, s_dim+1, ..., s_n).

Example

COUNT ((/.TRUE., .FALSE., .TRUE./)) has the value 2 because two elements are true.
COUNT ((/.TRUE., .TRUE., .TRUE./)) has the value 3 because three elements are true.

A is the array

\[
\begin{bmatrix}
1 & 5 & 7 \\
3 & 6 & 8
\end{bmatrix}
\]

and B is the array

\[
\begin{bmatrix}
0 & 5 & 7 \\
2 & 6 & 9
\end{bmatrix}
\]
COUNT (A .NE. B, DIM=1) tests to see how many elements in each column of A are not equal to the elements in the corresponding column of B. The result has the value (2, 0, 1) because:

- The first column of A and B have 2 elements that are not equal.
- The second column of A and B have 0 elements that are not equal.
- The third column of A and B have 1 element that is not equal.

COUNT (A .NE. B, DIM=2) tests to see how many elements in each row of A are not equal to the elements in the corresponding row of B. The result has the value (1, 2) because:

- The first row of A and B have 1 element that is not equal.
- The second row of A and B have 2 elements that are not equal.

The following shows another example:

```fortran
LOGICAL mask (2, 3)
INTEGER AR1(3), AR2(2), I
mask = RESHAPE((/ .TRUE., .TRUE., .FALSE., .TRUE., .FALSE., .FALSE./), (/2, 3/))

! mask is the array
! true false false
! true true false

AR1 = COUNT(mask, DIM=1) ! counts true elements by column yielding [2 1 0]

AR2 = COUNT(mask, DIM=2) ! counts true elements by row yielding [1 2]

I = COUNT(mask) ! returns 3
```

See Also
- C to D
- ALL
- ANY
**CPU_TIME**

*Intrinsic Subroutine (Generic):* Returns a processor-dependent approximation of the processor time in seconds. This is a new intrinsic procedure in Fortran 95. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

CALL CPU_TIME (time)

*time* (Output) Must be scalar and of type real.

If a meaningful time cannot be returned, a processor-dependent negative value is returned.

**Example**

Consider the following:

```fortran
REAL time_begin, time_end
...
CALL CPU_TIME ( time_begin )
!
! task to be timed
!
CALL CPU_TIME ( time_end )
PRINT (*,*) 'Time of operation was ', time_end - time_begin, ' seconds'
```

**CRITICAL**

*OpenMP* Fortran Compiler Directive: Restricts access to a block of code to only one thread at a time.

**Syntax**

```fortran
c$OMP CRITICAL [(name)]
    block
  c$OMP END CRITICAL [(name)]
```

2492
c Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

name Is the name of the critical section.

block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

A thread waits at the beginning of a critical section until no other thread in the team is executing a critical section having the same name. All unnamed CRITICAL directives map to the same name.

If a name is specified in the CRITICAL directive, the same name must appear in the corresponding END CRITICAL directive. If no name appears in the CRITICAL directive, no name can appear in the corresponding END CRITICAL directive.

Critical section names are global entities of the program. If the name specified conflicts with any other entity, the behavior of the program is undefined.

Example

The following example shows a queuing model in which a task is dequeued and worked on. To guard against multiple threads dequeuing the same task, the dequeuing operation is placed in a critical section.

Because there are two independent queues in this example, each queue is protected by CRITICAL directives having different names, XAXIS and YAXIS, respectively:

```c
  c$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,Y)
  c$OMP CRITICAL(XAXIS)
      CALL DEQUEUE(IX_NEXT, X)
  c$OMP END CRITICAL(XAXIS)
      CALL WORK(IX_NEXT, X)
  c$OMP CRITICAL(YAXIS)
      CALL DEQUEUE(IY_NEXT, Y)
  c$OMP END CRITICAL(YAXIS)
      CALL WORK(IY_NEXT, Y)
  c$OMP END PARALLEL
```

- C to D
OpenMP Fortran Compiler Directives

CSHIFT Transformational Intrinsic Function (Generic):
Performs a circular shift on a rank-one array, or performs circular shifts on all the complete rank-one sections (vectors) along a given dimension of an array of rank two or greater.

Syntax
Elements shifted off one end are inserted at the other end. Different sections can be shifted by different amounts and in different directions.

\[
\text{result} = \text{CSHIFT} (\text{array}, \text{shift} [, \text{dim}])
\]

- **array** (Input) Array whose elements are to be shifted. It can be of any data type.
- **shift** (Input; optional) Optional dimension along which to perform the shift. Must be a scalar integer or an array with a rank that is one less than \( \text{array} \), and shape \((d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n)\), where \((d_1, d_2, \ldots, d_n)\) is the shape of \( \text{array} \).
- **dim** (Input; optional) Optional dimension along which to perform the shift. Must be a scalar integer with a value in the range 1 to \( n \), where \( n \) is the rank of \( \text{array} \). If \( \text{dim} \) is omitted, it is assumed to be 1.

Results
The result is an array with the same type and kind parameters, and shape as \( \text{array} \).
If \( \text{array} \) has rank one, element \( i \) of the result is \( \text{array}(1 + \text{MODULO}(i + \text{shift}- 1, \text{SIZE}(\text{array}))) \). (The same shift is applied to each element.)
If \( \text{array} \) has rank greater than one, each section \((s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n)\) of the result is shifted as follows:
- By the value of \( \text{shift} \), if \( \text{shift} \) is scalar
- According to the corresponding value in \( \text{shift}(s_1, s_2, \ldots, s_{\text{dim}-1}, s_{\text{dim}+1}, \ldots, s_n) \), if \( \text{shift} \) is an array
The value of \textit{shift} determines the amount and direction of the circular shift. A positive \textit{shift} value causes a shift to the left (in rows) or up (in columns). A negative \textit{shift} value causes a shift to the right (in rows) or down (in columns). A zero \textit{shift} value causes no shift.

\textbf{Example}

V is the array $(1, 2, 3, 4, 5, 6)$.

\texttt{CSHIFT (V, SHIFT=2)} shifts the elements in V circularly to the \textit{left} by 2 positions, producing the value $(3, 4, 5, 6, 1, 2)$. 1 and 2 are shifted off the beginning and inserted at the end.

\texttt{CSHIFT (V, SHIFT=-2)} shifts the elements in V circularly to the \textit{right} by 2 positions, producing the value $(5, 6, 1, 2, 3, 4)$. 5 and 6 are shifted off the end and inserted at the beginning.

M is the array
\[
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9 
\end{bmatrix}
\]

\texttt{CSHIFT (M, SHIFT = 1, DIM = 2)} produces the result
\[
\begin{bmatrix}
2 & 3 & 1 \\
5 & 6 & 4 \\
8 & 9 & 7 
\end{bmatrix}
\]

Each element in rows 1, 2, and 3 is shifted to the \textit{left} by 2 positions. The elements shifted off the beginning are inserted at the end.

\texttt{CSHIFT (M, SHIFT = -1, DIM = 1)} produces the result
\[
\begin{bmatrix}
7 & 8 & 9 \\
1 & 2 & 3 \\
4 & 5 & 6 
\end{bmatrix}
\]

Each element in columns 1, 2, and 3 is shifted down by 1 position. The elements shifted off the end are inserted at the beginning.

\texttt{CSHIFT (M, SHIFT = (/1, -1, 0/), DIM = 2)} produces the result
\[
\begin{bmatrix}
2 & 3 & 1 \\
6 & 4 & 5 \\
7 & 8 & 9 
\end{bmatrix}
\]
Each element in row 1 is shifted to the \textit{left} by 1 position; each element in row 2 is shifted to the \textit{right} by 1 position; no element in row 3 is shifted at all.

The following shows another example:

\begin{verbatim}
INTEGER array (3, 3), AR1(3, 3), AR2 (3, 3)
DATA array /1, 4, 7, 2, 5, 8, 3, 6, 9/

! array is   1 2 3
!         4 5 6
!         7 8 9
!AR1 = CSHIFT(array, 1, DIM = 1) ! shifts all columns
! by 1 yielding
!         4 5 6
!         7 8 9
!         1 2 3
!

AR2=CSHIFT(array,shift=(/-1, 1, 0/),DIM=2) ! shifts
! each row separately
! by the amount in
! shift yielding
!         3 1 2
!         5 6 4
!         7 8 9
\end{verbatim}

\end{itemize}
CSMG

*Portability Function:* Performs an effective BIT-WISE store under mask.

**Module**

USE IFPORT

**Syntax**

result = CSMG (x, y, z)

x, y, z  (Input) INTEGER(4).

**Results**

The result type is INTEGER(4). The result is equal to the following expression:

\[(x \& z) \mid (y \& \sim z)\]

where "&" is a bitwise AND operation, | - bitwise OR, ~ - bitwise NOT.

The function returns the value based on the following rule: when a bit in z is 1, the output bit is taken from x. When a bit in z is zero, the corresponding output bit is taken from y.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

CTIME

*Portability Function:* Converts a system time into a 24-character ASCII string.

**Module**

USE IFPORT

**Syntax**

result = CTIME (stime)

stime  (Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.
Results

The result is a value in the form Mon Jan 31 04:37:23 1994. Hours are expressed using a 24-hour clock.

The value of \texttt{stime} can be determined by calling the \texttt{TIME} function. \texttt{CTIME(TIME( ))} returns the current time and date.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFFPORT

character (24) systime

systime = \texttt{CTIME(TIME( ))}

print *, 'Current date and time is ', systime

See Also

• \texttt{C to D}
• \texttt{DATE_AND_TIME}

\textbf{CYCLE}

\textit{Statement:} Interrupts the current execution cycle of the innermost (or named) \texttt{DO} construct.

\textbf{Syntax}

\begin{verbatim}
CYCLE \texttt{name}
\end{verbatim}

\texttt{name} \hspace{1cm} (Optional) Is the name of the \texttt{DO} construct.

\textbf{Description}

When a \texttt{CYCLE} statement is executed, the following occurs:

1. The current execution cycle of the named (or innermost) \texttt{DO} construct is terminated.

   If a \texttt{DO} construct name is specified, the \texttt{CYCLE} statement must be within the range of that construct.

2. The iteration count (if any) is decremented by 1.
3. The DO variable (if any) is incremented by the value of the increment parameter (if any).

Any executable statements following the CYCLE statement (including a labeled terminal statement) are not executed.

A CYCLE statement can be labeled, but it cannot be used to terminate a DO construct.

**Example**

The following example shows a CYCLE statement:

```plaintext
DO I =1, 10
  A(I) = C + D(I)
  IF (D(I) < 0) CYCLE ! If true, the next statement is omitted
  A(I) = 0 ! from the loop and the loop is tested again.
END DO
```
The following shows another example:

```fortran
sample_loop: do i = 1, 5
    print *,i
    if( i .gt. 3 ) cycle sample_loop
    print *,i
end do sample_loop
print *,'done!'```

!output:
! 1
! 1
! 2
! 2
! 3
! 3
! 4
! 5
! done!

- DO Constructs

**DATA**

*Statement*: Assigns initial values to variables before program execution.

**Syntax**

```
DATA var-list /clist/ [[,] var-list /clist/]...
```

`var-list` Is a list of variables or implied-DO lists, separated by commas.
Subscript expressions and expressions in substring references must be initialization expressions.

An implied-DO list in a DATA statement takes the following form:

\[(do\text{-}list, \text{var}\text{=}\text{expr}1, \text{expr}2[, \text{expr}3])\]

- **do-list**
  - Is a list of one or more array elements, substrings, scalar structure components, or implied-DO lists, separated by commas. Any array elements or scalar structure components must not have a constant parent.

- **var**
  - Is the name of a scalar integer variable (the implied-DO variable).

- **expr**
  - Is a list of variables or implied-DO lists, separated by commas.

- **clist**
  - Is a list of variables or implied-DO lists, separated by commas. A constant can be specified in the form \(r \ast \text{constant}\), where \(r\) is a repeat specification. It is a nonnegative scalar integer constant (with no kind parameter). If it is a named constant, it must have been declared previously in the scoping unit or made accessible through use or host association. If \(r\) is omitted, it is assumed to be 1.

**Description**

A variable can be initialized only once in an executable program. A variable that appears in a DATA statement and is typed implicitly can appear in a subsequent type declaration which may change the implicit typing.

The number of constants in \(c\text{-}list\) must equal the number of variables in \(var\text{-}list\). The constants are assigned to the variables in the order in which they appear (from left to right).

The following objects cannot be initialized in a DATA statement:

- A dummy argument
- A function
- A function result
- An automatic object
- An allocatable array
- A variable that is accessible by use or host association
- A variable in a named common block (unless the DATA statement is in a block data program unit)
- A variable in blank common
Except for variables in named COMMON blocks, a named variable has the SAVE attribute if any part of it is initialized in a DATA statement. You can confirm this property by specifying the variable in a SAVE statement or a type declaration statement containing the SAVE attribute.

When an unsubscripted array name appears in a DATA statement, values are assigned to every element of that array in the order of subscript progression. If the associated constant list does not contain enough values to fill the array, a warning is issued and the remaining array elements become undefined.

Array element values can be initialized in three ways: by name, by element, or by an implied-DO list (interpreted in the same way as a DO construct).

The following conversion rules and restrictions apply to variable and constant list items:

- If the constant and the variable are both of numeric type, the following conversion occurs:
  - The constant value is converted to the data type of the variable being initialized, if necessary.
  - When a binary, octal, or hexadecimal constant is assigned to a variable or array element, the number of digits that can be assigned depends on the data type of the data item. If the constant contains fewer digits than the capacity of the variable or array element, the constant is extended on the left with zeros. If the constant contains more digits than can be stored, the constant is truncated on the left. An error results if any nonzero digits are truncated.

- If the constant and the variable are both of character type, the following conversion occurs:
  - If the length of the constant is less than the length of the variable, the rightmost character positions of the variable are initialized with blank characters.
  - If the length of the constant is greater than the length of the variable, the character constant is truncated on the right.

- If the constant is of numeric type and the variable is of character type, the following restrictions apply:
  - The character variable must have a length of one character.
  - The constant must be an integer, binary, octal, or hexadecimal constant, and must have a value in the range 0 through 255.

When the constant and variable conform to these restrictions, the variable is initialized with the character that has the ASCII code specified by the constant. (This lets you initialize a character object to any 8-bit ASCII code.)
If the constant is a Hollerith or character constant, and the variable is a numeric variable or numeric array element, the number of characters that can be assigned depends on the data type of the data item.

If the Hollerith or character constant contains fewer characters than the capacity of the variable or array element, the constant is extended on the right with blank characters. If the constant contains more characters than can be stored, the constant is truncated on the right.

Example
The following example shows the three ways that DATA statements can initialize array element values:

```
DIMENSION A(10,10)
DATA A/10*1.0/   ! initialization by name
DATA A(1,1), A(10,1), A(3,3) /2*2.5, 2.0/  ! initialization by element
DATA ((A(I,J), I=1,5,2), J=1,5) /15*1.0/  ! initialization by implied-DO list
```

The following example shows DATA statements containing structure components:

```
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE

TYPE(EMPLOYEE) MAN_NAME, CON_NAME
DATA MAN_NAME / EMPLOYEE(417, 'Henry Adams') /
DATA CON_NAME%ID, CON_NAME%NAME / 891, "David James"/
```

In the following example, the first DATA statement assigns zero to all 10 elements of array A, and four asterisks followed by two blanks to the character variable STARS:

```
INTEGER A(10), B(10)
CHARACTER BELL, TAB, LF, FF, STARS*6
DATA A,STARS /10*0, '****'/
DATA BELL,TAB,LF,FF /7,9,10,12/
DATA {B(I), I=1,10,2} /5*1/
```
In this case, the second DATA statement assigns ASCII control character codes to the character variables BELL, TAB, LF, and FF. The last DATA statement uses an implied-DO list to assign the value 1 to the odd-numbered elements in the array B.

The following shows another example:

```fortran
INTEGER n, order, alpha, list(100)
REAL coef(4), eps(2),
pi(5), x(5,5)
CHARACTER*12 help
COMPLEX*8 cstuff
DATA n /0/, order /3/
DATA alpha /'A'/
DATA coef /1.0, 2*3.0, 1.0/, eps(1) /.00001/
DATA cstuff /(-1.0, -1.0)/
! The following example initializes diagonal and below in
! a 5x5 matrix:
DATA ((x(j,i), i=1,j), j=1,5) / 15*1.0 /
DATA pi / 5*3.14159 /
DATA list / 100*0 /
DATA help(1:4), help(5:8), help(9:12) /3*'HELP'/
```

Consider the following:

```fortran
CHARACTER (LEN = 10) NAME
INTEGER, DIMENSION (0:9) :: MILES
REAL, DIMENSION (100, 100) :: SKEW
TYPE (MEMBER) MYNAME, YOURS
DATA NAME / 'JOHN DOE' /, miles / 10*0 /
DATA ((SKEW (k, j), j = 1, k), k = 1, 100) / 5050*0.0 /
DATA ((SKEW (k, j), j = k + 1, 100), k = 1, 99) / 4950*1.0 /
DATA MYNAME / MEMBER (21, 'JOHN SMITH') /
DATA YOURS % age, YOURS % name / 35, 'FRED BROWN' /
```
In this example, the character variable NAME is initialized with the value JOHN DOE with two trailing blanks to fill out the declared length of the variable. The ten elements of MILES are initialized to zero. The two-dimensional array SKEW is initialized so that its lower triangle is zero and its upper triangle is one. The structures MYNAME and YOURS are declared using the derived type MEMBER. The derived-type variable MYNAME is initialized by a structure constructor. The derived-type variable YOURS is initialized by supplying a separate value for each component.

The first DATA statement in the previous example could also be written as:

```
DATA name / 'JOHN DOE' /
DATA miles / 10*0 /
```

As a Fortran 95 feature, a pointer can be initialized as disassociated by using a DATA statement. For example:

```
INTEGER, POINTER :: P
DATA P/NULL( )/
```

### DATE Intrinsic Procedure

**Intrinsic Subroutine (Generic):** Returns the current date as set within the system. DATE can be used as an intrinsic subroutine or as a portability
function or subroutine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

CALL DATE (buf)

(buf) Is a variable, array, or arrayelement of any data type, or a character substring. It must contain at least nine bytes of storage.

The date is returned as a 9-byte ASCII character string taking the form dd-mmm-yy, where:

- `dd` is the 2-digit date
- `mmm` is the 3-letter month
- `yy` is the last two digits of the year

If `buf` is of numeric type and smaller than 9 bytes, data corruption can occur.

If `buf` is of character type, its associated length is passed to the subroutine. If `buf` is smaller than 9 bytes, the subroutine truncates the date to fit in the specified length. If an array of type character is passed, the subroutine stores the date in the first array element, using the element length, not the length of the entire array.

---

CAUTION. The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

---

Example

CHARACTER*1 DAY(9)

...

CALL DATE (DAY)

The length of the first array element in CHARACTER array DAY is passed to the DATE subroutine. The subroutine then truncates the date to fit into the 1-character element, producing an incorrect result.

See Also

- C to D
- DATE_AND_TIME
DATE Portability Routine

Portability Function or Subroutine: Returns the current system date. DATE can be used as an intrinsic subroutine or as a portability function or subroutine. It is an intrinsic procedure unless you specify USE IFPORT.

Module

USE IFPORT

Syntax

Function Syntax:
result = DATE( )

Subroutine Syntax:
CALL DATE (dstring)

(dstring) (Output) CHARACTER. Is a variable or array containing at least nine bytes of storage.

DATE in its function form returns a CHARACTER string of length 8 in the form mm/dd/yy, where mm, dd, and yy are two-digit representations of the month, day, and year, respectively.

DATE in its subroutine form returns dstring in the form dd-mmm-yy, where dd is a two-digit representation of the current day of the month, mmm is a three-character abbreviation for the current month (for example, Jan) and yy are the last two digits of the current year.

CAUTION. The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

!If today's date is March 02, 2000, the following
!code prints "02-Mar-00"

CHARACTER(9) TODAY

CALL DATE(TODAY)

PRINT *, TODAY

!The next line prints "03/02/00"

PRINT *, DATE( )

See Also

• C to D
• DATE_AND_TIME
• DATE intrinsic procedure

DATE4

Portability Subroutine: Returns the current
system date.

Module

USE IFPORT

Syntax

CALL DATE4 (datestr)

datestr (Output) CHARACTER.

This subroutine returns datestr in the form dd-mmm-yyyy, where dd is a two-digit representation of the current day of the month, mmm is a three-character abbreviation for the current month (for example, Jan) and yyyy are the four digits of the current year.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
DATE_AND_TIME

Intrinsic Subroutine (Generic): Returns character data on the real-time clock and date in a form compatible with the representations defined in Standard ISO 8601:1988. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

CALL DATE_AND_TIME ( [date] [,time] [,zone] [,values] )

date (Output; optional) Must be scalar and of type default character; its length must be at least 8 to contain the complete value. Its leftmost 8 characters are set to a value of the form CCYYMMDD, where:

<table>
<thead>
<tr>
<th>CC</th>
<th>Is the century</th>
</tr>
</thead>
<tbody>
<tr>
<td>YY</td>
<td>Is the year within the century</td>
</tr>
<tr>
<td>MM</td>
<td>Is the month within the year</td>
</tr>
<tr>
<td>DD</td>
<td>Is the day within the month</td>
</tr>
</tbody>
</table>

time (Output; optional) Must be scalar and of type default character; its length must be at least 10 to contain the complete value. Its leftmost 10 characters are set to a value of the form hhmmss.sss, where:

<table>
<thead>
<tr>
<th>hh</th>
<th>Is the hour of the day</th>
</tr>
</thead>
<tbody>
<tr>
<td>mm</td>
<td>Is the minutes of the hour</td>
</tr>
<tr>
<td>ss.sss</td>
<td>Is the seconds and milliseconds of the minute</td>
</tr>
</tbody>
</table>

zone (Output; optional) Must be scalar and of type default character; its length must be at least 5 to contain the complete value. Its leftmost 5 characters are set to a value of the form hhmm, where
**hh** and **mm** are the time difference with respect to Coordinated Universal Time (UTC) in hours and parts of an hour expressed in minutes, respectively. UTC (also known as Greenwich Mean Time) is defined by CCIR Recommendation 460-2.

(values) (Output; optional) Must be of type integer. One-dimensional array with size of at least 8. The values returned in values are as follows:

<table>
<thead>
<tr>
<th>values(n)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>values(1)</td>
<td>Is the 4-digit year</td>
</tr>
<tr>
<td>values(2)</td>
<td>Is the month of the year</td>
</tr>
<tr>
<td>values(3)</td>
<td>Is the day of the month</td>
</tr>
<tr>
<td>values(4)</td>
<td>Is the time difference with respect to Coordinated Universal Time (UTC) in minutes</td>
</tr>
<tr>
<td>values(5)</td>
<td>Is the hour of the day (range 0 to 23) - local time</td>
</tr>
<tr>
<td>values(6)</td>
<td>Is the minutes of the hour (range 0 to 59) - local time</td>
</tr>
<tr>
<td>values(7)</td>
<td>Is the seconds of the minute (range 0 to 59) - local time</td>
</tr>
<tr>
<td>values(8)</td>
<td>Is the milliseconds of the second (range 0 to 999) - local time</td>
</tr>
</tbody>
</table>
Example

Consider the following example executed on 2000 March 28 at 11:04:14.5:

```fortran
INTEGER DATE_TIME (8)
CHARACTER (LEN = 12) REAL_CLOCK (3)
CALL DATE_AND_TIME (REAL_CLOCK (1), REAL_CLOCK (2), &
                     REAL_CLOCK (3), DATE_TIME)
```

This assigns the value "20000328" to REAL_CLOCK (1), the value "110414.500" to REAL_CLOCK (2), and the value "-0500" to REAL_CLOCK (3). The following values are assigned to DATE_TIME: 2000, 3, 28, -300, 11, 4, 14, and 500.

The following shows another example:

```fortran
CHARACTER(10) t
CHARACTER(5) z
CALL DATE_AND_TIME(TIME = t, ZONE = z)
```

DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN

**Portability Functions**: Compute the double-precision values of Bessel functions of the first and second kinds.

Module

```fortran
USE IFPORT
```
Syntax

result = DBESJ0 (value)
result = DBESJ1 (value)
result = DBESJN (n, value)
result = DBESY0 (posvalue)
result = DBESY1 (posvalue)
result = DBESYN (n, posvalue)

value (Input) REAL(8). Independent variable for a Bessel function.
n (Input) Integer. Specifies the order of the selected Bessel function computation.

posvalue (Input) REAL(8). Independent variable for a Bessel function. Must be greater than or equal to zero.

Results

DBESJ0, DBESJ1, and DBESJN return Bessel functions of the first kind, orders 0, 1, and n, respectively, with the independent variable posvalue.

DBESY0, DBESY1, and DBESYN return Bessel functions of the second kind, orders 0, 1, and n, respectively, with the independent variable posvalue.

Negative arguments cause DBESY0, DBESY1, and DBESYN to return a huge negative value.

Bessel functions are explained more fully in most mathematics reference books, such as the Handbook of Mathematical Functions (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT
real(8) besnum, besout
10 read *, besnum
   besout = dbesj0(besnum)
   print *, 'result is ',besout
   goto 10
end

DBLE

*Elemental Intrinsic Function (Generic):*
Converting a number to double-precision real type.

Syntax
result = DBLE (a)

a

(Input) Must be of type integer, real, or complex.

Results
The result type is double precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If a is of type double precision, the result is the value of the a with no conversion (DBLE( a ) = a).

If a is of type integer or real, the result has as much precision of the significant part of a as a double precision value can contain.

If a is of type complex, the result has as much precision of the significant part of the real part of a as a double precision value can contain.
<table>
<thead>
<tr>
<th>Specific Name 1</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(1)</td>
<td>REAL(8)</td>
<td></td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>REAL(8)</td>
<td></td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>REAL(8)</td>
<td></td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>REAL(8)</td>
<td></td>
</tr>
<tr>
<td>DBLE 2</td>
<td>REAL(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DBLEQ</td>
<td>REAL(16)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(16)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

1 These specific functions cannot be passed as actual arguments.

2 The setting of compiler options specifying double size can affect DBLE.

**Example**

DBLE (4) has the value 4.0.

DBLE ((3.4, 2.0)) has the value 3.4.

**See Also**

- C to D
- FLOAT
- SNGL
- REAL
- CMPLX
DCLOCK

**Portability Function:** Returns the elapsed time in seconds since the start of the current process.

**Module**

USE IFPORT

**Syntax**

```fortran
result = DCLOCK()
```

**Results**

The result type is REAL(8). This routine provides accurate timing to the nearest microsecond, taking into account the frequency of the processor where the current process is running. You can obtain equivalent results using standard Fortran by using the CPU_TIME intrinsic subroutine. Note that the first call to DCLOCK performs calibration.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
USE IFPORT
DOUBLE PRECISION START_TIME, STOP_TIME, DCLOCK
EXTERNAL DCLOCK
START_CLOCK = DCLOCK()
CALL FOO()
STOP_CLOCK = DCLOCK()
PRINT *, 'foo took:', STOP_CLOCK - START_CLOCK, 'seconds.'
```

**See Also**

- C to D
- DATE_AND_TIME
- CPU_TIME
DCMPLX

Elemental Intrinsic Function (Specific):
Converting the argument to double complex type.
This function cannot be passed as an actual argument.

Syntax
result = DCMPLX (x[,y])

x (Input) Must be of type integer, real, or complex.
y (Input; optional) Must be of type integer or real. It must not be present if x is of type complex.

Results
The result type is double complex (COMPLEX(8) or COMPLEX*16).
If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If y is not specified and x is complex, the result value is CMPLX(REAL(x), AIMAG(x)).
If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.
DCMPLX(x, y) has the complex value whose real part is REAL(x, KIND=8) and whose imaginary part is REAL(y, KIND=8).

Example
DCMPLX (-3) has the value (-3.0, 0.0).
DCMPLX (4.1, 2.3) has the value (4.1, 2.3).

- REAL
DEALLOCATE

Statement: Frees the storage allocated for allocatable arrays and pointer targets (and causes the pointers to become disassociated).

Syntax

DEALLOCATE (object[,object]...[, alloc-opt])

object (Output) Is one of the following:

alloc-opt

STAT=sv sv is a scalar integer variable in which the status of the deallocation is stored.

ERRMSG=ev ev is a scalar default character value in which an error condition is stored if such a condition occurs.

Description

If a STAT variable or ERRMSG variable is specified, it must not be deallocated in the DEALLOCATE statement in which it appears. If the deallocation is successful, the variable is set to zero. If the deallocation is not successful, an error condition occurs, and the variable is set to a positive integer value (representing the run-time error); the ERRMSG variable contains the error condition. If no STAT variable is specified and an error condition occurs, program execution terminates.

It is recommended that all explicitly allocated storage be explicitly deallocated when it is no longer needed.

To disassociate a pointer that was not associated with the ALLOCATE statement, use the NULLIFY statement.

For a list of run-time errors, see Building Applications.
**Example**

The following example shows deallocation of an allocatable array:

```fortran
INTEGER ALLOC_ERR

REAL, ALLOCATABLE :: A(:,), B(:, :)
...
ALLOCATE (A(10), B(-2:8,1:5))
...
DEALLOCATE(A, B, STAT = ALLOC_ERR)
```

The following shows another example:

```fortran
INTEGER, ALLOCATABLE :: dataset(:, :, :)
INTEGER reactor, level, points, error
DATA reactor, level, points / 10, 50, 10 /
ALLOCATE (dataset(1:reactor,1:level,1:points), STAT = error)
DEALLOCATE (dataset, STAT = error)
```

**See Also**
- C to D
- ALLOCATE
- NULLIFY
- Arrays
- Dynamic Allocation

**DECLARE and NODECLARE**

*General Compiler Directives:* `DECLARE` generates warnings for variables that have been used but have not been declared (like the `IMPLICIT NONE` statement). `NODECLARE` (the default) disables these warnings.

**Syntax**

```fortran
cDEC$ DECLARE
cDEC$ NODECLARE
```
The DECLARE directive is primarily a debugging tool that locates variables that have not been properly initialized, or that have been defined but never used.

Building Applications: Compiler Directives Related to Options

**DECODE**

**Statement:** Translates data from character to internal form. It is comparable to using internal files in formatted sequential READ statements.

**Syntax**

DECODE \((c, f, b[, \text{IOSTAT}=i-var] [, \text{ERR}=label])\) [io-list]

- **\(c\)**: Is a scalar integer expression. It is the number of characters to be translated to internal form.
- **\(f\)**: Is a format identifier. An error occurs if more than one record is specified.
- **\(b\)**: Is a scalar or array reference. If \(b\) is an array reference, its elements are processed in the order of subscript progression. \(b\) contains the characters to be translated to internal form.
- **\(i-var\)**: Is a scalar integer variable that is defined as a positive integer if an error occurs and as zero if no error occurs (see I/O Status Specifier).
- **\(label\)**: Is the label of an executable statement that receives control if an error occurs.
- **\(io-list\)**: Is an I/O list. An I/O list is either an implied-DO list or a simple list of variables (except for assumed-size arrays). The list receives the data after translation to internal form. The interaction between the format specifier and the I/O list is the same as for a formatted I/O statement.
The number of characters that the DECODE statement can translate depends on the data type of \( b \). For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.

**Example**

In the following example, the DECODE statement translates the 12 characters in A to integer form (as specified by the FORMAT statement):

```fortran
DIMENSION K(3)
CHARACTER*12 A,B
DATA A/'123456789012'/
DECODE(12,100,A) K
100 FORMAT(3I4)
ENCODE(12,100,B) K(3), K(2), K(1)
```

The 12 characters are stored in array K:

- \( K(1) = 1234 \)
- \( K(2) = 5678 \)
- \( K(3) = 9012 \)

DEFAULT Clause

Parallel Directive Clause: Lets you specify a scope for all variables in the lexical extent of a parallel region.

Syntax

DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE )

The specifications have the following effects:

- PRIVATE - Makes all named objects in the lexical extent of the parallel region, including common block variables but excluding THREADPRIVATE variables, private to a thread as if you explicitly listed each variable in a PRIVATE clause.
- FIRSTPRIVATE - Makes all variables in the construct that have implicitly determined data-sharing attributes firstprivate as if you explicitly listed each variable in a FIRSTPRIVATE clause.
- SHARED - Makes all named objects in the lexical extent of the parallel region shared among the threads in a team, as if you explicitly listed each variable in a SHARED clause. If you do not specify a DEFAULT clause, this is the default.
- NONE - Specifies that there is no implicit default as to whether variables are PRIVATE or SHARED. In this case, you must specify the PRIVATE, SHARED, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION property of each variable you use in the lexical extent of the parallel region.

You can specify only one DEFAULT clause in a PARALLEL directive. You can exclude variables from a defined default by using the PRIVATE, SHARED, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION clauses.

Variables in THREADPRIVATE common blocks are not affected by this clause.

- C to D

Optimizing Applications: DEFAULT Clause
**DEFINE and UNDEFINE**

**General Compiler Directives:** *DEFINE creates a symbolic variable whose existence or value can be tested during conditional compilation. UNDEFINE removes a defined symbol.*

**Syntax**

```fortran
C DEC$ DEFINE name[ = val]
C DEC$ UNDEFINE name
```

- `c` Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- `name` Is the name of the variable.
- `val` INTEGER(4). The value assigned to `name`.

_DEFINE and UNDEFINE removes symbols for use with the IF (or IF DEFINED) compiler directive. Symbols defined with DEFINE directive are local to the directive. They cannot be declared in the Fortran program.

Because Fortran programs cannot access the named variables, the names can duplicate Fortran keywords, intrinsic functions, or user-defined names without conflict.

To test whether a symbol has been defined, use the IF DEFINED (name) directive. You can assign an integer value to a defined symbol. To test the assigned value of `name`, use the IF directive. IF test expressions can contain most logical and arithmetic operators.

Attempting to undefine a symbol that has not been defined produces a compiler warning.

The DEFINE and UNDEFINE directives can appear anywhere in a program, enabling and disabling symbol definitions.
Example

!DEC$ DEFINE testflag
!DEC$ IF DEFINED (testflag)
   write (*,*) 'Compiling first line'
!DEC$ ELSE
   write (*,*) 'Compiling second line'
!DEC$ ENDIF
!DEC$ UNDEFINE testflag

Building Applications: Using Predefined Preprocessor Symbols

DEFINE FILE

**Statement:** Establishes the size and structure of files with relative organization and associates them with a logical unit number.

**Syntax**

```
DEFINE FILE u(m, n, U, asv) [, u(m, n, U, asv)] ...
```

- **u**
  Is a scalar integer constant or variable that specifies the logical unit number.

- **m**
  Is a scalar integer constant or variable that specifies the number of records in the file.

- **n**
  Is a scalar integer constant or variable that specifies the length of each record in 16-bit words (2 bytes).

- **U**
  Specifies that the file is unformatted (binary); this is the only acceptable entry in this position.
Is a scalar integer variable, called the associated variable of the file. At the end of each direct access I/O operation, the record number of the next higher numbered record in the file is assigned to `asv`; `asv` must not be a dummy argument.

The DEFINE FILE statement is comparable to the OPEN statement. In situations where you can use the OPEN statement, OPEN is the preferable mechanism for creating and opening files.

The DEFINE FILE statement specifies that a file containing \( m \) fixed-length records, each composed of \( n \) 16-bit words, exists (or will exist) on the specified logical unit. The records in the file are numbered sequentially from 1 through \( m \).

A DEFINE FILE statement does not itself open a file. However, the statement must be executed before the first direct access I/O statement referring to the specified file. The file is opened when the I/O statement is executed.

If this I/O statement is a WRITE statement, a direct access sequential file is opened, or created if necessary.

If the I/O statement is a READ or FIND statement, an existing file is opened, unless the specified file does not exist. If a file does not exist, an error occurs.

The DEFINE FILE statement establishes the variable `asv` as the associated variable of a file. At the end of each direct access I/O operation, the Fortran I/O system places in `asv` the record number of the record immediately following the one just read or written.

The associated variable always points to the next sequential record in the file (unless the associated variable is redefined by an assignment, input, or FIND statement). So, direct access I/O statements can perform sequential processing on the file by using the associated variable of the file as the record number specifier.

**Example**

```
DEFINE FILE 3(1000,48,U,NREC)
```

In this example, the DEFINE FILE statement specifies that the logical unit 3 is to be connected to a file of 1000 fixed-length records; each record is forty-eight 16-bit words long. The records are numbered sequentially from 1 through 1000 and are unformatted.

After each direct access I/O operation on this file, the integer variable `NREC` will contain the record number of the record immediately following the record just processed.

**DELDIRQQ**

*Portability Function:* Deletes a specified directory.

---

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{DELDIRQQ}\ (\text{dir})
\]

*dir*  
(Input) Character*(*). String containing the path of the directory to be deleted.

**Results**

The result type is LOGICAL(4). The result is `.TRUE.` if successful; otherwise, `.FALSE.`.

The directory to be deleted must be empty. It cannot be the current directory, the root directory, or a directory currently in use by another process.

---

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

See the example for GETDRIVEDIRQQ.

DELETE

Statement: Deletes a record from a relative file.

Syntax

DELETE ([UNIT=] io-unit, REC= r[, ERR= label] [, IOSTAT=i-var])

io-unit Is an external unit specifier.

r Is a scalar numeric expression indicating the record number to be deleted.

label Is the label of the branch target statement that receives control if an error occurs.

i-var Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

In a relative file, the DELETE statement deletes the direct access record specified by r. If REC= r is omitted, the current record is deleted. When the direct access record is deleted, any associated variable is set to the next record number.

The DELETE statement logically removes the appropriate record from the specified file by locating the record and marking it as a deleted record. It then frees the position formerly occupied by the deleted record so that a new record can be written at that position.

NOTE. You must use compiler option vms for READs to detect that a record has been deleted.

Example

The following statement deletes the fifth record in the file connected to I/O unit 10:

DELETE (10, REC=5)

Suppose the following statement is specified:

DELETE (UNIT=9, REC=10, IOSTAT=IOS, ERR=20)

The tenth record in the file connected to unit 9 is deleted. If an error occurs, control is transferred to the statement labeled 20, and a positive integer is stored in the variable IOS.

• C to D
Data Transfer I/O Statements
Branch Specifiers
vms compiler option

DELETEMENUQQ (W*32, W*64)

QuickWin Function: Deletes a menu item from a QuickWin menu.

Module
USE IFQWIN

Syntax

result = DELETEMENUQQ (menuID, itemID)

menuID (Input) INTEGER(4). Identifies the menu that contains the menu item to be deleted, starting with 1 as the leftmost menu.

itemID (Input) INTEGER(4). Identifies the menu item to be deleted, starting with 0 as the top menu item.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

Compatibility

QUICKWIN GRAPHICS LIB
Example

USE IFQWIN

LOGICAL(4) result

CHARACTER(25) str

str = 'Add to EDIT Menu' ! Append to 2nd menu

result = APPENDMENUQQ(2, $MENUENABLED, str, WINSTATUS)

! Delete third item (EXIT) from menu 1 (FILE)

result = DELETEMENUQQ(1, 3)

! Delete entire fifth menu (WINDOW)

result = DELETEMENUQQ(5, 0)

END

- MODIFYMENUROUTINEQQ
- MODIFYMENUSTRINGQQ

Building Applications: Using QuickWin Overview
Building Applications: Program Control of Menus

DELFILESQQ

Portability Function: Deletes all files matching the name specification, which can contain wildcards (* and ?).

Module

USE IFPORT

Syntax

result = DELFILESQQ (files)
files

(Input) Character*(*). Files to be deleted. Can contain wildcards (* and ?).

Results
The result type is INTEGER(2). The result is the number of files deleted.
You can use wildcards to delete more than one file at a time. DELFILESQQ does not delete directories or system, hidden, or read-only files. Use this function with caution because it can delete many files at once. If a file is in use by another process (for example, if it is open in another process), it cannot be deleted.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
USE IFCORE
INTEGER(4) len, count
CHARACTER(80) file
CHARACTER(1) ch
WRITE(*,*) "Enter names of files to delete: 
len = GETSTRQQ(file)
IF (file(1:len) .EQ. '*.*') THEN
   WRITE(*,*) "Are you sure (Y/N)?"
   ch = GETCHARQQ()
   IF ((ch .NE. 'Y') .AND. (ch .NE. 'y')) STOP
END IF
count = DELFILESQQ(file)
WRITE(*,*) "Deleted ", count, " files."
END

• C to D
**TYPE Statement (Derived Types)**

**Statement:** Declares a variable to be a derived type. It specifies the name of the user-defined type and the types of its components.

**Syntax**

```
TYPE [[, type-attr-spec-list] :: ] name

component-definition
  [component-definition]...

END TYPE [ name ]
```

- **type-attr-spec-list** is access-spec or BIND (C).
- **access-spec** is the PUBLIC or PRIVATE keyword. The keyword can only be specified if the derived-type definition is in the specification part of a module.
- **name** is the name of the derived data type. It must not be the same as the name of any intrinsic type, or the same as the name of a derived type that can be accessed from a module.
- **component-definition** is one or more type declaration statements defining the component of derived type.
  The first component definition can be preceded by an optional PRIVATE or SEQUENCE statement. (Only one PRIVATE or SEQUENCE statement can appear in a given derived-type definition.)
  If SEQUENCE is present, all derived types specified in component definitions must be sequence types.

A component definition takes the following form:

```
type[ [, attr] :: ] component[( a-spec)] [ *char-len] [ init-ex]
```

- **type** is a type specifier. It can be an intrinsic type or a previously defined derived type. (If the POINTER attribute follows this specifier, the type can also be any accessible derived type, including the type being defined.)
Is an optional POINTER attribute for a pointer component, or an optional DIMENSION or ALLOCATABLE attribute for an array component. You cannot specify both the ALLOCATABLE and POINTER attribute. If DIMENSION is specified, it can be followed by an array specification. Each attribute can only appear once in a given component-definition.

component Is the name of the component being defined.

a-spec Is an optional array specification, enclosed in parentheses. If POINTER or ALLOCATABLE is specified, the array is deferred shape; otherwise, it is explicit shape. In an explicit-shape specification, each bound must be a constant scalar integer expression. If the array bounds are not specified here, they must be specified following the DIMENSION attribute.

char-len Is an optional scalar integer literal constant; it must be preceded by an asterisk (*). This parameter can only be specified if the component is of type CHARACTER.

init-ex Is an initialization expression, or for pointer components, => NULL( ). This is a Fortran 95 feature. If init-ex is specified, a double colon must appear in the component definition. The equals assignment symbol (=) can only be specified for nonpointer components. The initialization expression is evaluated in the scoping unit of the type definition.

**Description**

If a name is specified following the END TYPE statement, it must be the same name that follows TYPE in the derived type statement.
A derived type can be defined only once in a scoping unit. If the same derived-type name appears in a derived-type definition in another scoping unit, it is treated independently.

A component name has the scope of the derived-type definition only. Therefore, the same name can be used in another derived-type definition in the same scoping unit.

Two data entities have the same type if they are both declared to be of the same derived type (the derived-type definition can be accessed from a module or a host scoping unit).

If the entities are in different scoping units, they can also have the same derived type if they are declared with reference to different derived-type definitions, and if both derived-type definitions have all of the following:

- The same name
- A SEQUENCE statement (they both have sequence type)
- Components that agree in name, order, and attributes; components cannot be private

If BIND (C) is specified, the following rules apply:

- The derived type cannot be a SEQUENCE type.
- The derived type must have type parameters.
- Each component of the derived type must be a nonpointer, nonallocatable data component with interoperable type and type parameters.
Example

! DERIVED.F90
! Define a derived-type structure, type variables, and assign values
TYPE member
    INTEGER age
    CHARACTER (LEN = 20) name
END TYPE member

TYPE (member) :: george
TYPE (member) :: ernie
george = member( 33, 'George Brown' )
ernie%age = 56
ernie%name = 'Ernie Brown'
WRITE (*,*) george
WRITE (*,*) ernie
END
The following shows another example of a derived type:

```fortran
TYPE mem_name
  SEQUENCE
  CHARACTER (LEN = 20) lastn
  CHARACTER (LEN = 20) firstn
  CHARACTER (len = 3) cos ! this works because COS is a component name
END TYPE mem_name

TYPE member
  TYPE (mem_name) :: name
  SEQUENCE
  INTEGER age
  CHARACTER (LEN = 20) specialty
END TYPE member

In the following example, a and b are both variable arrays of derived type pair:

```fortran
TYPE (pair)
  INTEGER i, j
END TYPE

TYPE (pair), DIMENSION (2, 2) :: a, b(3)
```
The following example shows how you can use derived-type objects as components of other derived-type objects:

```fortran
TYPE employee_name
    CHARACTER(25) last_name
    CHARACTER(15) first_name
END TYPE

TYPE employee_addr
    CHARACTER(20) street_name
    INTEGER(2) street_number
    INTEGER(2) apt_number
    CHARACTER(20) city
    CHARACTER(2) state
    INTEGER(4) zip
END TYPE

Objects of these derived types can then be used within a third derived-type specification, such as:

```fortran
TYPE employee_data
    TYPE (employee_name) :: name
    TYPE (employee_addr) :: addr
    INTEGER(4) telephone
    INTEGER(2) date_of_birth
    INTEGER(2) date_of_hire
    INTEGER(2) social_security(3)
    LOGICAL(2) married
    INTEGER(2) dependents
END TYPE
```

DFLOAT

**Elemental Intrinsic Function (Generic):**

*Converts an integer to double-precision real type.*

**Syntax**

```
result = DFLOAT (a)
```

*a*  
(Input) Must be of type integer.

**Results**

The result type is double-precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

<table>
<thead>

</tbody>
</table>
Specific Name | Argument Type | Result Type
---|---|---
1 These specific functions cannot be passed as actual arguments.
2 The setting of compiler options specifying double size can affect DFLOAT.

Example
DFLOAT (-4) has the value -4.0.

See Also
- C to D
- REAL

DFLOATI, DFLOATJ, DFLOATK

Portability Functions: Convert an integer to double-precision real type.

Module
USE IFPORT

Syntax
result = DFLOATI (i)
result = DFLOATJ (j)
result = DFLOATK (k)

i (Input) Must be of type INTEGER(2).
j (Input) Must be of type INTEGER(4).
k (Input) Must be of type INTEGER(8).

Results
The result type is double-precision real (REAL(8) or REAL*8).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also
- C to D
- DFLOAT

DIGITS

*Inquiry Intrinsic Function (Generic):* Returns the number of significant digits for numbers of the same type and kind parameters as the argument.

Syntax

```fortran
result = DIGITS (x)
```

x  
(Input) Must be of type integer or real; it can be scalar or array valued.

Results

The result is a scalar of type default integer.

The result has the value \( q \) if \( x \) is of type integer; it has the value \( p \) if \( x \) is of type real. Integer parameter \( q \) is defined in Model for Integer Data; real parameter \( p \) is defined in Model for Real Data.

Example

If \( x \) is of type REAL(4), DIGITS(x) has the value 24.

See Also
- C to D

**DIM**

*Elemental Intrinsic Function (Generic):*

Returns the difference between two numbers (if the difference is positive).

**Syntax**

\[ \text{result} = \text{DIM}(x, y) \]

- \(x\) (Input) Must be of type integer or real.
- \(y\) (Input) Must have the same type and kind parameters as \(x\).

**Results**

The result type is the same as \(x\). The value of the result is \(x - y\) if \(x\) is greater than \(y\); otherwise, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument type</th>
<th>Result Type</th>

</tr>
<tr>
<td>QDIM</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)Or HDIM.

\(^2\)Or JIDIM. For compatibility, IDIM can also be specified as a generic function for integer types.

**Example**

DIM (6, 2) has the value 4.
DIM (-4.0, 3.0) has the value 0.0.
The following shows another example:

```fortran
INTEGER i
REAL r
REAL(8) d
i = IDIM(10, 5) ! returns 5
r = DIM (-5.1, 3.7) ! returns 0.0
d = DDIM (10.0D0, -5.0D0) ! returns 15.0D0
```

See Also
- C to D
- Argument Keywords in Intrinsic Procedures

DIMENSION

Statement and Attribute: Specifies that an object is an array, and defines the shape of the array.

Syntax
The DIMENSION attribute can be specified in a type declaration statement or a DIMENSION statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
  type, [att-ls,] DIMENSION (a-spec) [, att-ls] :: a[(a-spec)] [ , a[(a-spec)] ] ... 
```

**Statement:**

```fortran
  DIMENSION [::] a(a-spec) [, a(a-spec) ] ... 
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `a-spec` Is an array specification. It can be any of the following:
  - An explicit-shape specification; for example, `a(10,10)`
  - An assumed-shape specification; for example, `a(:)`
  - A deferred-shape specification; for example, `a(:,:)`
  - An assumed-size specification; for example, `a(10,:)`
For more information on array specifications, see Declaration Statements for Arrays.

In a type declaration statement, any array specification following an array overrides any array specification following DIMENSION.

a

Is the name of the array being declared.

**Description**

The DIMENSION attribute allocates a number of storage elements to each array named, one storage element to each array element in each dimension. The size of each storage element is determined by the data type of the array.

The total number of storage elements assigned to an array is equal to the number produced by multiplying together the number of elements in each dimension in the array specification. For example, the following statement defines ARRAY as having 16 real elements of 4 bytes each and defines MATRIX as having 125 integer elements of 4 bytes each:

```
DIMENSION ARRAY(4,4), MATRIX(5,5,5)
```

An array can also be declared in the following statements: ALLOCATABLE, AUTOMATIC, COMMON, POINTER, STATIC, TARGET.

**Example**

The following examples show type declaration statements specifying the DIMENSION attribute:

```
REAL, DIMENSION(10, 10) :: A, B, C(10, 15) ! Specification following C
    ! overrides the one following
    ! DIMENSION

REAL(8), DIMENSION(5,-2:2) :: A,B,C
```

The following are examples of the DIMENSION statement:

```
DIMENSION BOTTOM(12,24,10)
DIMENSION X(5,5,5), Y(4,85), Z(100)
DIMENSION MARK(4,4,4,4)
SUBROUTINE APROC(A1,A2,N1,N2,N3)
    DIMENSION A1(N1:N2), A2(N3:*)
CHARACTER(LEN = 20) D
DIMENSION A(15), B(15, 40), C(-5:8, 7), D(15)
```
You can also declare arrays by using type and ALLOCATABLE statements, for example:

```
INTEGER A(2,0:2)

COMPLEX F

ALLOCATABLE F(:,:)

REAL(8), ALLOCATABLE, DIMENSION(:, :, :) :: E
```

You can specify both the upper and lower dimension bounds. If, for example, one array contains data from experiments numbered 28 through 112, you could dimension the array as follows:

```
DIMENSION experiment(28:112)
```

Then, to refer to the data from experiment 72, you would reference `experiment(72)`.

Array elements are stored in column-major order: the leftmost subscript is incremented first when the array is mapped into contiguous memory addresses. For example, consider the following statements:

```
INTEGER(2) a(2, 0:2)

DATA a /1, 2, 3, 4, 5, 6/
```

These are equivalent to:

```
INTEGER(2) a

DIMENSION a(2, 0:2)

DATA a /1, 2, 3, 4, 5, 6/
```

If `a` is placed at location 1000 in memory, the preceding DATA statement produces the following mapping.

<table>
<thead>
<tr>
<th>Array element</th>
<th>Address</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>a(1,0)</td>
<td>1000</td>
<td>1</td>
</tr>
<tr>
<td>a(2,0)</td>
<td>1002</td>
<td>2</td>
</tr>
<tr>
<td>a(1,1)</td>
<td>1004</td>
<td>3</td>
</tr>
<tr>
<td>a(2,1)</td>
<td>1006</td>
<td>4</td>
</tr>
<tr>
<td>a(1,2)</td>
<td>1008</td>
<td>5</td>
</tr>
<tr>
<td>a(2,2)</td>
<td>100A</td>
<td>6</td>
</tr>
</tbody>
</table>
The following DIMENSION statement defines an assumed-size array in a subprogram:

```
DIMENSION data (19,*)
```

At execution time, the array data is given the size of the corresponding array in the calling program.

The following program fragment dimensions two arrays:

```
... 
SUBROUTINE Subr (matrix, rows, vector)
REAL MATRIX, VECTOR
INTEGER ROWS
DIMENSION MATRIX (ROWS,*), VECTOR (10),
+ LOCAL (2,4,8)
MATRIX (1,1) = VECTOR (5)
...
```

DISPLAYCURSOR (W*32, W*64)

**Graphics Function:** Controls cursor visibility.

Module

USE IFQWIN

Syntax

```
result = DISPLAYCURSOR (toggle)
```

`toggle` (Input) INTEGER(2). Constant that defines the cursor state. Has two possible values:

- **$GCURSOROFF** - Makes the cursor invisible regardless of its current shape and mode.
$GCURSORON - Makes the cursor always visible in graphics mode.

Results
The result type is INTEGER(2). The result is the previous value of toggle.
Cursor settings hold only for the currently active child window. You need to call DISPLAYCURSOR for each window in which you want the cursor to be visible.
A call to SETWINDOWCONFIG turns off the cursor.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also
- C to D
- SETTEXTCURSOR
- SETWINDOWCONFIG

DISTRIBUTE POINT

General Compiler Directive: Specifies loop distribution.

Syntax
```
c DEC$ DISTRIBUTE POINT
```

Loop distribution causes large loops to be distributed (split) into smaller ones. The resulting loops contain a subset of the instructions from the initial loop. Loop distribution can enable software pipelining to be applied to more loops. It can also reduce register pressure and improve both instruction and data cache use.

If the directive is placed before a loop, the compiler will determine where to distribute; data dependencies are observed.

If the directive is placed inside a loop, the distribution is performed after the directive and any loop-carried dependencies are ignored. Currently only one distribute directive is supported if the directive is placed inside the loop.
Example

!DEC$ DISTRIBUTE POINT

do i =1, m
  b(i) = a(i) +1
  ....
  c(i) = a(i) + b(i) ! Compiler will decide
  ! where to distribute.
  ! Data dependencies are
  ! observed
  ....
  d(i) = c(i) + 1
endo

do i =1, m
  b(i) = a(i) +1
  ....

!DEC$ DISTRIBUTE POINT

call sub(a, n)! Distribution will start here,
  ! ignoring all loop-carried
  ! dependencies
  c(i) = a(i) + b(i)
  ....
  d(i) = c(i) + 1
endo

DLGEXIT (W*32, W*64)

Dialog Subroutine: Closes an open dialog box.

Module
USE IFLOGM

Syntax
CALL DLGEXIT (dlg)

dlg
( Input ) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

If you want to exit a dialog box on a condition other than the user selecting the OK or Cancel button, you need to include a call to DLGEXIT from within your callback routine. DLGEXIT saves the data associated with the dialog box controls and then closes the dialog box. The dialog box is exited after DLGEXIT has returned control back to the dialog manager, not immediately after the call to DLGEXIT.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
SUBROUTINE EXITSUB (dlg, exit_button_id, callbacktype)
USE IFLOGM
TYPE (DIALOG) dlg
INTEGER exit_button_id, callbacktype
...
CALL DLGEXIT (dlg)

• DLGMODELESS

Building Applications: Setting Return Values and Exiting

DLGFLUSH (W*32, W*64)

Dialog Subroutine: Updates the display of a dialog box.

Module

USE IFLOGM

Syntax

CALL DLGFLUSH (dlg[,flushall])

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

flushall (Input; optional) Logical. If .FALSE. (the default), then only the controls that the dialog routines have marked as changed are updated. If .TRUE., all controls are updated with the state of the controls as known by the dialog routines. Normally, you would not set flushall to .TRUE..

When your application calls DLGSET to change a property of a control in a dialog box, the change is not immediately reflected in the displayed dialog box. Changes are applied when the dialog box is first displayed, and then after every dialog callback to the user's code.

This design expects that, after a call to DLGMODAL or DLGMODELESS, every call to DLGSET will be made from within a callback routine, and that the callback routine finishes quickly. This is true most of the time.

However, there may be cases where you want to change a control outside of a dialog callback, or from within a loop in a dialog callback.
In these cases, DLGFLUSH is required, but is not always sufficient, to update the dialog display. DLGFLUSH sends pending Windows* system messages to the dialog box and the controls that it contains. However, many display changes do not appear until after the program reads and processes these messages. A loop that processes the pending messages may be required; for example:

```fortran
use IFWINTY
use USER32
use IFLOGM
logical lNotQuit, lret
integer iret
TYPE (T_MSG) mesg
lNotQuit = .TRUE.
do while (lNotQuit .AND. (PeekMessage(mesg, 0, 0, 0, PM_NOREMOVE) <> 0))
   lNotQuit = GetMessage(mesg, NULL, 0, 0)
   if (lNotQuit) then
      if (DLGISDLGMESSAGE(mesg) .EQV. .FALSE) then
         lret = TranslateMessage(mesg)
         iret = DispatchMessage(mesg)
      end if
   end if
end do
```

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

- DLGMODAL
- DLGMODELESS
- DLGSET
- DLGSETSUB
DLGGET, DLGGETINT, DLGGETLOG, DLGGETCHAR (W*32, W*64)

Dialog Functions: Return the state of the dialog control variable.

Module

USE IFLOGM

Syntax

result = DLGGET (dlg, controlid, value[, index])
result = DLGGETINT (dlg, controlid, value[, index])
result = DLGGETLOG (dlg, controlid, value[, index])
result = DLGGETCHAR (dlg, controlid, value[, index])

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

controlid (Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).

value (Output) Integer, logical, or character. The value of the control's variable.

index (Input; optional) Integer. Specifies the control variable whose value is retrieved. Necessary if the control has more than one variable of the same data type and you do not want to get the value of the default for that type.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

Use the DLGGET functions to retrieve the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variable associated with it, but not necessarily all. The control variables are listed in the table in Building Applications: Control Indexes. The types of controls they are associated with are listed in the table in Building Applications: Available Indexes for Each Dialog Control.
You can use DLGGET to retrieve the value of any variable. You can also use DLGGETINT to retrieve an integer value, or DLGGETLOG and DLGGETCHAR to retrieve logical and character values, respectively. If you use DLGGET, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to retrieve a variable type that is not available, the DLGGET functions return .FALSE..

If two or more controls have the same controlid, you cannot use these controls in a DLGGET operation. In this case the function returns .FALSE..

The dialog box does not need to be open to access its control variables.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFLOGM

INCLUDE "THISDLG.FD"

TYPE (DIALOG) dig

INTEGER val

LOGICAL retlog, is_checked

CHARACTER(256) text

...

retlog = DLGGET (dig, IDC_CHECKBOX1, is_checked, dig_status)

retlog = DLGGET (dig, IDC_SCROLLBAR2, val, dig_range)

retlog = DLGGET (dig, IDC_STATIC_TEXT1, text, dig_title)

...

**Building Applications:** Using Edit Boxes

**Building Applications:** Using Scroll Bars

---

**DLGINIT, DLGINITWITHRESOURCEHANDLE (W*32, W*64)**

**Dialog Functions:** Initialize a dialog box.

**Module**

USE IFLOGM

**Syntax**

result = DLGINIT (id, dlg)

result = DLGINITWITHRESOURCEHANDLE (id, hinst, dlg)

**id**  
(Input) INTEGER(4). Dialog identifier. Can be either the symbolic name for the dialog or the identifier number, both listed in the Include file (with extension .FD).

**dlg**  
(Output) Derived type dialog. Contains dialog box parameters.

**hinst**  
(Input) INTEGER(4). Module instance handle in which the dialog resource can be found.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

DLGINIT must be called to initialize a dialog box before it can be used with DLGMODAL, DLGMODELESS, or any other dialog function.

DLGINIT will only search for the dialog box resource in the main application. For example, it will not find a dialog box resource that has been built into a dynamic link library.

DLGINITWITHRESOURCEHANDLE can be used when the dialog resource is not in the main application. If the dialog resource is in a dynamic link library (DLL), hinst must be the value passed as the first argument to the DLLMAIN procedure.

Dialogs can be used from any application, including console, QuickWin, and Windows* applications.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFLOGM
INCLUDE 'DLG1.FD'
LOGICAL retlog
TYPE (DIALOG) thisdlg
...
retlog = DLGINIT (IDD_DLG3, thisdlg)
IF (.not. retlog) THEN
  WRITE (*,*) 'ERROR: dialog not found'
ELSE
...

Building Applications: Initializing and Activating the Dialog Box

DLGISDLGMESSAGE, DLGISDLGMESSAGEWITHDLG (W*32, W*64)

Dialog Functions: Determine whether the
specified message is intended for one of the
currently displayed modeless dialog boxes, or a
specific dialog box.

Module
USE IFLOGM
Syntax

\[
\text{result} = \text{DLGISDLGMESSAGE} \ (\text{msg})
\]

\[
\text{result} = \text{DLGISDLGMESSAGEWITHDLG} \ (\text{msg}, \text{dlg})
\]

\text{msg}  \quad (\text{Input}) \quad \text{Derived type T\_MSG. Contains a Windows message.}

\text{dlg}  \quad (\text{Input}) \quad \text{Derived type dialog. Contains dialog box parameters.}

The components of the type \text{dialog} are defined with the \text{PRIVATE} attribute, and cannot be changed or individually accessed by the user.

Results

The result type is \text{LOGICAL(4)}. The result is \text{.TRUE.} if the message is processed by the dialog box. Otherwise, the result is \text{.FALSE.} and the message should be further processed.

\text{DLGISDLGMESSAGE} must be called in the message loop of Windows applications that display a modeless dialog box using \text{DLGMODELESS}. \text{DLGISDLGMESSAGE} determines whether the message is intended for one of the currently displayed modeless dialog boxes. If it is, it passes the message to the dialog box to be processed.

\text{DLGISDLGMESSAGEWITHDLG} specifies a particular dialog box to check. Use \text{DLGISDLGMESSAGEWITHDLG} when the message loop is in a main application and the currently active modeless dialog box was created by a DLL.

Compatibility

\text{WINDOWS}
Example

use IFLOGM
include 'resource.fd'
type (DIALOG) dlg

type (T_MSG) mesg

integer*4 ret

logical*4 lret

...!

! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub(dlg, IDD_THERM_DIALOG, ThermSub)
...
lret = DlgModeless(dlg, nCmdShow)
...

! Read and process messsages

do while( GetMessage (mesg, NULL, 0, 0) )
  ! Note that DlgIsDlgMessage must be called in order to give
  ! the dialog box first chance at the message.
  if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
    lret = TranslateMessage( mesg )
    ret = DispatchMessage( mesg )
  end if
end do

! Cleanup dialog box memory and exit the application

call DlgUninit(dlg)

WinMain = mesg%wParam

return
See Also

• DLGMODELESS

Building Applications: Using a Modeless Dialog Box

DLGMODAL, DLGMODALWITHPARENT (W*32, W*64)

Dialog Functions: Display a dialog box and process user control selections made within the box.

Module
USE IFLOGM

Syntax
result = DLGMODAL (dlg)
result = DLGMODAL (dlg, hwndParent)

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

hwndParent (Input) Integer. Specifies the parent window for the dialog box. If omitted, the value is determined in this order:

1. If DLGMODAL is called from the callback of a modal or modeless dialog box, then that dialog box is the parent window.
2. If it is a QuickWin or Standard Graphics application, then the frame window is the parent window.
3. The Windows* desktop window is the parent window.

Results
The result type is INTEGER(4). By default, if successful, it returns the identifier of the control that caused the dialog to exit; otherwise, it returns -1. The return value can be changed with the DLGSETRETURN subroutine.
During execution, DLGMODAL displays a dialog box and then waits for user control selections. When a control selection is made, the callback routine, if any, of the selected control (set with DLGSETHSU) is called.

The dialog remains active until an exit control is executed: either the default exit associated with the OK and Cancel buttons, or DLGEXIT within your own control callbacks. DLGMODAL does not return a value until the dialog box is exited.

The default return value for DLGMODAL is the identifier of the control that caused it to exit (for example, IDOK for the OK button and IDCANCEL for the Cancel button). You can specify your own return value with DLGSETRETURN from within one of your dialog control callback routines. You should not specify -1 as your return value, because this is the error value DLGMODAL returns if it cannot open the dialog.

Use DLGMODALWITHPARENT when you want the parent window to be other than the default value (see argument hwndParent above). In particular, in an SDI or MDI Windows application, you may want the parent window to be the main application window. The parent window is disabled for user input while the modal dialog box is displayed.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFLOGM
INCLUDE "MYDLG.FD"
INTEGER return
TYPE (DIALOG) mydialog
...
return = DLGMODAL (mydialog)
...

- DLGEXIT
**DLGMODELESS (W*32, W*64)**

**Dialog Function:** Displays a modeless dialog box.

**Module**

USE IFLOGM

**Syntax**

```plaintext
result = DLGMODELESS (dlg[, nCmdShow, hwndParent])
```

**dlg**

(Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user. The variable passed to this function must remain in memory for the duration of the dialog box, that is from the DLGINIT call through the DLGUNINIT call.

The variable can be declared as global data in a module, as a variable with the STATIC attribute, or in a calling procedure that is active for the duration of the dialog box. It must not be an AUTOMATIC variable in the procedure that calls DLGMODELESS.

**nCmdShow**

(Input) Integer. Specifies how the dialog box is to be shown. It must be one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW_HIDE</td>
<td>Hides the dialog box.</td>
</tr>
<tr>
<td>SW_MINIMIZE</td>
<td>Minimizes the dialog box.</td>
</tr>
<tr>
<td>SW_RESTORE</td>
<td>Activates and displays the dialog box. If the dialog box is minimized or maximized, the Windows system restores it to its original size and position.</td>
</tr>
</tbody>
</table>

```
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SW_SHOW</td>
<td>Activates the dialog box and displays it in its current size and position.</td>
</tr>
<tr>
<td>SW_SHOWMAXIMIZED</td>
<td>Activates the dialog box and displays it as a maximized window.</td>
</tr>
<tr>
<td>SW_SHOWMINIMIZED</td>
<td>Activates the dialog box and displays it as an icon.</td>
</tr>
<tr>
<td>SW_SHOWMINNOACTIVE</td>
<td>Displays the dialog box as an icon. The window that is currently active remains active.</td>
</tr>
<tr>
<td>SW_SHOWNA</td>
<td>Displays the dialog box in its current state. The window that is currently active remains active.</td>
</tr>
<tr>
<td>SW_SHOWNOACTIVATE</td>
<td>Displays the dialog box in its most recent size and position. The window that is currently active remains active.</td>
</tr>
<tr>
<td>SW_SHOWNORMAL</td>
<td>Activates and displays the dialog box. If the dialog box is minimized or maximized, the Windows system restores it to its original size and position.</td>
</tr>
</tbody>
</table>

The default value is SW_SHOWNORMAL.

*(Input) Integer. Specifies the parent window for the dialog box. The default value is determined in this order:*

1. If DLGMODELESS is called from a callback of a modeless dialog box, then that dialog box is the parent window.
2. The Windows desktop window is the parent window.

**Results**

The result type is LOGICAL(4). The value is .TRUE. if the function successfully displays the dialog box. Otherwise the result is .FALSE..

During execution, DLGMODELESS displays a modeless dialog box and returns control to the calling application. The dialog box remains active until DLGEXIT is called, either explicitly or as the result of the invocation of a default button callback.

DLGMODELESS is typically used in a Windows application. The application must contain a message loop that processes Windows messages. The message loop must call DLGISDLGMESSAGE for each message. See the example below in the Example section. Multiple modeless dialog boxes can be displayed at the same time. A modal dialog box can be displayed from a modeless dialog box by calling DLGMODAL from a modeless dialog callback. However, DLGMODELESS cannot be called from a modal dialog box callback.

DLGMODELESS also can be used in a Console, DLL, or LIB project. However, the requirements remain that the application must contain a message loop and must call DLGISDLGMESSAGE for each message. For an example of calling DLGMODELESS in a DLL project, see the Dllprgrs sample in the . . . \SAMPLES\DIALOG\folder.

Use the DLG_INIT callback with DLGSETSUB to perform processing immediately after the dialog box is created and before it is displayed, and to perform processing immediately before the dialog box is destroyed.

**Compatibility**

WINDOWS CONSOLE DLL LIB
Example

use IFLOGM
include 'resource.fd'
type (DIALOG)   dlg
type (T_MSG)    mesg
integer*4      ret
logical*4      lret
...
! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub( dlg, IDD_THERM_DIALOG, TherSub)
...
lret = DlgModeless( dlg, nCmdShow)
...
! Read and process messages
do while( GetMessage (mesg, NULL, 0, 0) )
   ! Note that DlgIsDlgMessage must be called in order to give
   ! the dialog box first chance at the message.
   if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
      lret = TranslateMessage( mesg )
      ret = DispatchMessage( mesg )
   end if
end do
! Cleanup dialog box memory and exit the application
call DlgUninit( dlg)
WinMain = mesg%wParam
return

Building Applications: Using a Modeless Dialog Box

**DLGSENDCTRLMESSAGE (W*32, W*64)**

*Dialog Function:* Sends a Windows message to a dialog box control.

**Module**
USE IFLOGM

**Syntax**

```fortran
result = DLGSENDCTRLMESSAGE (dlg, controlid, msg, wparam, lparam)
```

*dlg*
(Input) Derived type `dialog`. Contains dialog box parameters. The components of the type `dialog` are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

*controlid*
(Input) Integer. Specifies the identifier of the control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).

*msg*
(Input) Integer. Derived type `T_MSG`. Specifies the message to be sent.

*wparam, lparam*
(Input) Integer. Specifies additional message specific information.

**Results**

The result type is INTEGER(4). The value specifies the result of the message processing and depends upon the message sent.

The dialog box must be currently active by a call to DLGMODAL or DLGMODELESS. This function does not return until the message has been processed by the control.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
use IFLOGM
include 'resource.fd'
type (dialog) dlg
integer callbacktype
integer cref
integer iret
if (callbacktype == dlg_init) then
  ! Change the color of the Progress bar to red
  ! NOTE: The following message succeeds only if Internet Explorer 4.0
  ! or later is installed
  cref = Z'FF'  ! Red
  iret = DlgSendCtrlMessage(dlg, IDC_PROGRESS1, PBM_SETBARCOLOR, 0, cref)
endif

DLGSET, DLGSETINT, DLGSETLOG, DLGSETCHAR (W*32, W*64)
Dialog Functions: Set the values of dialog control variables.

Module
USE IFLOGM
Syntax

result = DLGSET (dlg, controlid, value[, index])
result = DLGSETINT (dlg, controlid, value[, index])
result = DLGSETLOG (dlg, controlid, value[, index])
result = DLGSETCHAR (dlg, controlid, value[, index])

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

controlid (Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension .FD).

value (Input) Integer, logical, or character. The value of the control's variable.

index (Input; optional) Integer. Specifies the control variable whose value is set. Necessary if the control has more than one variable of the same data type and you do not want to set the value of the default for that type.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

Use the DLGSET functions to set the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variables associated with it, but not necessarily all. The control variables are listed in the table in Building Applications: Control Indexes. The types of controls they are associated with are listed in the table in Building Applications: Available Indexes for Each Dialog Control.

You can use DLGSET to set any control variable. You can also use DLGSETINT to set an integer variable, or DLGSETLOG and DLGSETCHAR to set logical and character values, respectively. If you use DLGSET, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to set a variable type that is not available, the DLGSET functions return .FALSE.
Calling DLGSET does not cause a callback routine to be called for the changing value of a control. In particular, when inside a callback, performing a DLGSET on a control does not cause the associated callback for that control to be called. Callbacks are invoked automatically only by user action on the controls in the dialog box. If the callback routine needs to be called, you can call it manually after the DLGSET is executed.

If two or more controls have the same controlid, you cannot use these controls in a DLGSET operation. In this case the function returns .FALSE..

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**DLGSETCTRLEVENTHANDLER (W*32, W*64)**

*Dialog Function:* Assigns user-written event handlers to ActiveX controls in a dialog box.

**Module**

USE IFLOGM

**Syntax**

```fortran
result = DLGSETCTRLEVENTHANDLER (dlg, controlid, handler, dispid[, iid])
```

- **dlg** (Input) Derived type *dialog*. Contains dialog box parameters. The components of the type *dialog* are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

- **controlid** (Input) Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension .FD) file.

- **handler** (Input) Name of the routine to be called when the event occurs. It must be declared EXTERNAL.

- **dispid** (Input) Integer. Specifies the member id of the method in the event interface that identifies the event.

- **iid** (Input; optional) Derived type GUID, which is defined in the IFWINTY module. Specifies the interface identifier of the source (event) interface. If omitted, the default source interface of the ActiveX control is used.

**Results**

The result type is INTEGER(4). The result is an HRESULT describing the status of the operation.

When the ActiveX control event occurs, the handler associated with the event is called. You call DLGSETCTRLEVENTHANDLER to specify the handler to be called.

The events supported by an ActiveX control and the interfaces of the handlers are determined by the ActiveX control.

You can find this information in one of the following ways:

- By reading the documentation of the ActiveX control.
• By using a tool that lets you examine the type information of the ActiveX control, such as the OLE-COM Object Viewer.
• By using the Fortran Module Wizard to generate a module that contains Fortran interfaces to the ActiveX control, and examining the generated module.

The handler that you define in your application must have the interface that the ActiveX control expects, including calling convention and parameter passing mechanisms. Otherwise, your application will likely crash in unexpected ways because of the application's stack getting corrupted.

Note that an object is always the first parameter in an event handler. This object value is a pointer to the control's source (event) interface, not the IDispatch pointer of the control. You can use DLGGET with the DLG_IDISPATCH index to retrieve the control's IDispatch pointer.

For more information, see Building Applications: Using ActiveX Controls Overview.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFLOGM
ret = DlgSetCtrlEventHandler( &
   dlg, &

Building Applications: Setting Return Values and Exiting

DLGSETSUB (W*32, W*64)

Dialog Function: Assigns your own callback subroutines to dialog controls and to the dialog box.

Module

USE IFLOGM
Syntax

result = DLGSETSUB (dlg, controlid, value[, index])

dlg   (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

controlid (Input) Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension .FD) file, or it can be the identifier of the dialog box.

value   (Input) EXTERNAL. Name of the routine to be called when the callback event occurs.

index   (Input; optional) Integer. Specifies which callback routine is executed when the callback event occurs. Necessary if the control has more than one callback routine.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

When a callback event occurs (for example, when you select a check box), the callback routine associated with that callback event is called. You use DLGSETSUB to specify the subroutine to be called. All callback routines should have the following interface:

SUBROUTINE callbackname( dlg, control_id, callbacktype)

!DEC$ ATTRIBUTES DEFAULT :: callbackname
callbackname Is the name of the callback routine.
dlg Refers to the dialog box and allows the callback to change values of the dialog controls.
control_id Is the name of the control that caused the callback.
callbacktype (Input; optional) Integer. Specifies which callback routine is executed when the callback event occurs. Necessary if the control has more than one callback routine.
The **control_id** and **callbacktype** parameters let you write a single subroutine that can be used with multiple callbacks from more than one control. Typically, you do this for controls comprising a logical group. You can also associate more than one callback routine with the same control, but you must use then use **index** parameter to indicate which callback routine to use.

The **control_id** can also be the identifier of the dialog box. The dialog box supports two **callbacktype**s, DLG_INIT and DLG_SIZECHANGE. The DLG_INIT callback is executed immediately after the dialog box is created with **callbacktype**DLG_INIT, and immediately before the dialog box is destroyed with **callbacktype**DLG_DESTROY. DLG_SIZECHANGE is called when the size of a dialog is changed.

Callback routines for a control are called after the value of the control has been updated based on the user's action.

If two or more controls have the same **controlid**, you cannot use these controls in a DLGSETSUB operation. In this case, the function returns .FALSE..

For more information, see *Building Applications*: Dialog Callback Routines.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

PROGRAM DLGPROG
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (dialog) mydialog

Building Applications: Initializing and Activating the Dialog Box

DLGSETTITLE (W*32, W*64)

*Dialog Subroutine: Sets the title of a dialog box.*

**Module**
USE IFLOGM

**Syntax**
CALL DLGSETTITLE (dlg,title)

*dlg* (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

*title* (Input) Character*(*)*. Specifies text to be the title of the dialog box.

Use this routine when you want to specify the title for a dialog box.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) mydialog
LOGICAL retlog
...
retlog = DLGINIT(IDD_mydlg, mydialog)
...
CALL DLGSETTITLE(mydialog, "New Title")
...

• DLGMODELESS

DLGUNINIT (W*32, W*64)

Module
USE IFLOGM

Syntax
CALL DLGUNINIT (dlg)

dlg (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.
You should call DLGUNINIT when a dialog that was successfully initialized by DLGINIT is no longer needed. DLGUNINIT should only be called on a dialog initialized with DLGINIT. If it is called on an uninitialized dialog or one that has already been deallocated with DLGUNINIT, the result is undefined.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFLOGM

INCLUDE "MYDLG.FD"

TYPE (DIALOG) mydialog

LOGICAL retlog

...

retlog = DLGINIT(IDD_mydlg, mydialog)

...

CALL DLGUNINIT (mydialog)
END

*Building Applications*: Initializing and Activating the Dialog Box

**DNUM**

_Elemental Intrinsic Function (Specific):_

Converts a character string to a REAL(8) value. This function cannot be passed as an actual argument.

**Syntax**

result = DNUM (i)
Results
The result type is REAL(8). The result value is the double-precision real value represented by
the character string $i$.

Example
DNUM ("3.14159") has the value 3.14159 of type REAL(8).
The following sets $x$ to 311.0:
    CHARACTER(3) $i$
    DOUBLE PRECISION $x$
    $i$ = "311"
    $x$ = DNUM($i$)

DO Statement
Statement: Marks the beginning of a DO construct. The DO construct controls the repeated
execution of a block of statements or constructs.
(This repeated execution is called a loop.)

Syntax
A DO construct takes one of the following forms:
Block Form:
    [name:] DO [label[, ] ] [loop-control]
        block
    [label] term-stmt
Nonblock Form:
DO label [,] [loop-control]
    block
    [label] ex-term-stmt
name  (Optional) Is the name of the DO construct.
label (Optional) Is a statement label identifying the terminal statement.
loop-control Is a DO iteration (see Iteration Loop Control) or a DO WHILE statement.

block Is a sequence of zero or more statements or constructs.

term-stmt Is the terminal statement for the block form of the construct.

ex-term-stmt Is the terminal statement for the nonblock form of the construct.

**Description**

The terminal statement (term-stmt) for a block DO construct is an END DO or CONTINUE statement. If the block DO statement contains a label, the terminal statement must be identified with the same label. If no label appears, the terminal statement must be an END DO statement.

If a construct name is specified in a block DO statement, the same name must appear in the terminal END DO statement. If no construct name is specified in the block DO statement, no name can appear in the terminal END DO statement.

The terminal statement (ex-term-stmt) for a nonblock DO construct is an executable statement (or construct) that is identified by the label specified in the nonblock DO statement. A nonblock DO construct can share a terminal statement with another nonblock DO construct. A block DO construct cannot share a terminal statement.

The following cannot be terminal statements for nonblock DO constructs:

- CONTINUE (allowed if it is a shared terminal statement)
- CYCLE
- END (for a program or subprogram)
- EXIT
- GO TO (unconditional or assigned)
- Arithmetic IF
- RETURN
- STOP

The nonblock DO construct is an obsolete feature in Fortran 95 and Fortran 90.
Example

The following example shows a simple block DO construct (contains no iteration count or DO WHILE statement):

```
DO
  READ *, N
  IF (N == 0) STOP
  CALL SUBN
END DO
```

The DO block executes repeatedly until the value of zero is read. Then the DO construct terminates.

The following example shows a named block DO construct:

```
LOOP_1: DO I = 1, N
  A(I) = C * B(I)
END DO LOOP_1
```

The following example shows a nonblock DO construct with a shared terminal statement:

```
DO 20 I = 1, N
  DO 20 J = 1 + I, N
20  RESULT(I,J) = 1.0 / REAL(I + J)
```
The following two program fragments are also examples of DO statements:

C Initialize the even elements of a 20-element real array
C
DIMENSION array(20)
DO j = 2, 20, 2
    array(j) = 12.0
END DO
C
C Perform a function 11 times
C
DO k = -30, -60, -3
    int = j / 3
    isb = -9 - k
    array(isb) = MyFunc (int)
END DO

The following shows the final value of a DO variable (in this case 11):

DO j = 1, 10
    WRITE (*, '(I5)') j
END DO
WRITE (*, '(I5)') j

DO Directive

OpenMP* Fortran Compiler Directive: Specifies that the iterations of the immediately following DO loop must be executed in parallel.

Syntax

c$OMP DO [clause[,, clause] ... ]

do_loop
[ c$OMP END DO [NOWAIT]]

c Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

clause Is one of the following:

- FIRSTPRIVATE (list)
- LASTPRIVATE (list)
- ORDERED
  Must be used if ordered sections are contained in the dynamic extent of the DO directive. For more information about ordered sections, see the ORDERED directive.
- PRIVATE (list)
- REDUCTION (operator | intrinsic : list)
- SCHEDULE (type[, chunk])
  Specifies how iterations of the DO loop are divided among the threads of the team. chunk must be a scalar integer expression. The following four types are permitted, three of which allow the optional parameter chunk:

<table>
<thead>
<tr>
<th>Type</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATIC</td>
<td>Divides iterations into contiguous pieces by dividing the number of iterations by the number of threads in the</td>
</tr>
<tr>
<td>Type</td>
<td>Effect</td>
</tr>
<tr>
<td>-----------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>team</td>
<td>Each piece is then dispatched to a thread before loop execution begins.</td>
</tr>
<tr>
<td></td>
<td>If chunk is specified, iterations are divided into pieces of a size specified by chunk. The pieces are statically dispatched to threads in the team in a round-robin fashion in the order of the thread number.</td>
</tr>
<tr>
<td>DYNAMIC</td>
<td>Can be used to get a set of iterations dynamically. It defaults to 1 unless chunk is specified.</td>
</tr>
<tr>
<td></td>
<td>If chunk is specified, the iterations are broken into pieces of a size specified by chunk. As each thread finishes a piece of the iteration space, it dynamically gets the next set of iterations.</td>
</tr>
<tr>
<td>GUIDED</td>
<td>Can be used to specify a minimum number of iterations. It defaults to 1 unless chunk is specified.</td>
</tr>
<tr>
<td></td>
<td>If chunk is specified, the chunksize is reduced exponentially with each succeeding dispatch. The chunk specifies the minimum number of iterations to dispatch each time. If there</td>
</tr>
</tbody>
</table>
EffectType are less than chunk iterations remaining, the rest are dispatched.

AUTO\(^1\) Delegates the scheduling decision until compile time or run time. The schedule is processor dependent. The programmer gives the implementation the freedom to choose any possible mapping of iterations to threads in the team.

RUNTIME\(^1\) Defers the scheduling decision until run time. You can choose a schedule type and chunksize at run time by using the environment variable OMP_SCHEDULE.

\(^1\)No chunk is permitted for this type.

If the SCHEDULE clause is not used, the default schedule type is STATIC.

do_loop Is a DO iteration (an iterative DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO directive.

If used, the END DO directive must appear immediately after the end of the loop. If you do not specify an END DO directive, an END DO directive is assumed at the end of the DO loop.
If you specify NOWAIT in the END DO directive, threads do not synchronize at the end of the parallel loop. Threads that finish early proceed straight to the instruction following the loop without waiting for the other members of the team to finish the DO directive.

Parallel DO loop control variables are block-level entities within the DO loop. If the loop control variable also appears in the LASTPRIVATE list of the parallel DO, it is copied out to a variable of the same name in the enclosing PARALLEL region. The variable in the enclosing PARALLEL region must be SHARED if it is specified in the LASTPRIVATE list of a DO directive.

Only a single SCHEDULE clause and ORDERED clause can appear in a DO directive.

DO directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.

Example

In the following example, the loop iteration variable is private by default, and it is not necessary to explicitly declare it. The END DO directive is optional:

```fortran
C$OMP PARALLEL
C$OMP DO
   DO I=1,N
       B(I) = (A(I) + A(I-1)) / 2.0
   END DO
C$OMP END DO
C$OMP END PARALLEL
```
If there are multiple independent loops within a parallel region, you can use the NOWAIT option to avoid the implied BARRIER at the end of the DO directive, as follows:

```c
c$OMP PARALLEL
  c$OMP DO
      DO I=2,N
          B(I) = (A(I) + A(I-1)) / 2.0
      END DO
  c$OMP END DO NOWAIT
  c$OMP DO
      DO I=1,M
          Y(I) = SQRT(Z(I))
      END DO
  c$OMP END DO NOWAIT
  c$OMP END PARALLEL
```

Correct execution sometimes depends on the value that the last iteration of a loop assigns to a variable. Such programs must list all such variables as arguments to a LASTPRIVATE clause so that the values of the variables are the same as when the loop is executed sequentially, as follows:

```c
  c$OMP PARALLEL
  c$OMP DO LASTPRIVATE(I)
      DO I=1,N
          A(I) = B(I) + C(I)
      END DO
  c$OMP END PARALLEL
  CALL REVERSE(I)
```

In this case, the value of I at the end of the parallel region equals N+1, as in the sequential case.
Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```fortran
C$OMP DO ORDERED SCHEDULE(DYNAMIC)
DO I=LB,UB,ST
   CALL WORK(I)
END DO
...
SUBROUTINE WORK(K)
C$OMP ORDERED
   WRITE(*,*) K
C$OMP END ORDERED
```

**See Also**
- C to D
- OpenMP Fortran Compiler Directives
- Rules for General Directives that Affect DO Loops

**DO WHILE**

*Statement:* Executes the range of a DO construct while a specified condition remains true.

**Syntax**

```
DO [label[, ] ] WHILE (expr)
label
   (Optional) Is a label specifying an executable statement in the same program unit.
expr
   Is a scalar logical (test) expression enclosed in parentheses.
```

**Description**

Before each execution of the DO range, the logical expression is evaluated. If it is true, the statements in the body of the loop are executed. If it is false, the DO construct terminates and control transfers to the statement following the loop.

If no label appears in a DO WHILE statement, the DO WHILE loop must be terminated with an END DO statement.
You can transfer control out of a DO WHILE loop but not into a loop from elsewhere in the program.

**Example**

The following example shows a DO WHILE statement:

```fortran
CHARACTER*132 LINE
...
I = 1
DO WHILE (LINE(I:I) .EQ. ' ')
   I = I + 1
END DO
```

The following examples show required and optional END DO statements:

<table>
<thead>
<tr>
<th>Required</th>
<th>Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>DO WHILE (I .GT. J)</td>
<td>DO 10 WHILE (I .GT. J)</td>
</tr>
<tr>
<td>ARRAY(I,J) = 1.0</td>
<td>ARRAY(I,J) = 1.0</td>
</tr>
<tr>
<td>I = I - 1</td>
<td>I = I - 1</td>
</tr>
<tr>
<td>END DO</td>
<td>10 END DO</td>
</tr>
</tbody>
</table>

The following shows another example:

```fortran
CHARACTER(1) input
input = ' '
DO WHILE ((input .NE. 'n') .AND. (input .NE. 'y'))
   WRITE (*, '(A)') 'Enter y or n: '
   READ (*, '(A)') input
END DO
```

DOT_PRODUCT
Transformational Intrinsic Function (Generic):
Performs dot-product multiplication of numeric or logical vectors (rank-one arrays).

Syntax
result = DOT_PRODUCT (vector_a, vector_b)

vector_a (Input) Must be a rank-one array of numeric (integer, real, or complex) or logical type.

vector_b (Input) Must be a rank-one array of numeric type if vector_a is of numeric type, or of logical type if vector_a is of logical type. It must be the same size as vector_a.

Results
The result is a scalar whose type depends on the types of vector_a and vector_b.
If vector_a is of type integer or real, the result value is SUM (vector_a* vector_b).
If vector_a is of type complex, the result value is SUM (CONJG (vector_a)* vector_b).
If vector_a is of type logical, the result has the value ANY (vector_a .AND. vector_b).
If either rank-one array has size zero, the result is zero if the array is of numeric type, and false if the array is of logical type.

Example
DOT_PRODUCT ((/1, 2, 3/), (/3, 4, 5/)) has the value 26, calculated as follows:
((1 x 3) + (2 x 4) + (3 x 5)) = 26

DOT_PRODUCT ((/ (1.0, 2.0), (2.0, 3.0) /), (/ (1.0, 1.0), (1.0, 4.0) /)) has the value (17.0, 4.0).

DOT_PRODUCT ((/ .TRUE., .FALSE. /), (/ .FALSE., .TRUE. /)) has the value false.

The following shows another example:
I = DOT_PRODUCT((/1,2,3/), (/4,5,6/)) ! returns
! the value 32
DOUBLE COMPLEX

Statement: Specifies the DOUBLE COMPLEX data type.

Syntax

DOUBLE COMPLEX

A COMPLEX(8) or DOUBLE COMPLEX constant is a pair of constants that represents a complex number. One of the pair must be a double-precision real constant, the other can be an integer, single-precision real, or double-precision real constant.

A COMPLEX(8) or DOUBLE COMPLEX constant occupies 16 bytes of memory and is interpreted as a complex number.

The rules for DOUBLE PRECISION (REAL(8)) constants also apply to the double precision portion of COMPLEX(KIND=8) or DOUBLE COMPLEX constants. (For more information, see REAL and DOUBLE PRECISION.)

The DOUBLE PRECISION constants in a COMPLEX(8) or DOUBLE COMPLEX constant have IEEE* T_floating format.

Example

DOUBLE COMPLEX vector, arrays(7,29)

DOUBLE COMPLEX pi, pi2 /3.141592654,6.283185308/

The following examples demonstrate valid and invalid COMPLEX(KIND=8) or DOUBLE COMPLEX constants:

Valid

(547.3E0_8,-1.44_8)
(1.7039E0,-1.7039D0)
(+12739D3,0.D0)
(1.23D0,) Second constant missing.
(1D1,2H12) Hollerith constants not allowed.
(1,1.2) Neither constant is DOUBLE PRECISION; this is a valid single-precision real constant.

See Also
• C to D
• General Rules for Complex Constants
• COMPLEX Statement
• Complex Data Types
• DOUBLE PRECISION
• REAL

DOUBLE PRECISION
Statement: Specifies the DOUBLE PRECISION data type.

Syntax
DOUBLE PRECISION
A REAL(8) or DOUBLE PRECISION constant has more than twice the accuracy of a REAL(4) number, and greater range.
A REAL(8) or DOUBLE PRECISION constant occupies eight bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 15 digits are significant.
IEEE* T_floating format is used.
For more information, see General Rules for Real Constants.

Example
DOUBLE PRECISION varnam
DOUBLE PRECISION,PRIVATE :: zz

Table 789: Valid REAL(8) or DOUBLE PRECISION constants

- Real Data Types

DPROD

**Elemental Intrinsic Function (Specific):**
Produces a higher precision product. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

**Syntax**

result = DPROD (x, y)
(Input) Must be of type REAL(4) or REAL(8).

\( y \)

(Input) Must have the same type and kind parameters as \( x \).

**Results**

If \( x \) and \( y \) are of type REAL(4), the result type is double-precision real (REAL(8) or REAL*8).

If \( x \) and \( y \) are of type REAL(8), the result type is REAL(16). The result value is equal to \( x \times y \).

The setting of compiler options specifying real size can affect this function.

**Example**

DPROD (2.0, -4.0) has the value -8.00D0.

DPROD (5.0D0, 3.0D0) has the value 15.00Q0.

The following shows another example:

\[
\begin{align*}
\text{REAL(4)} & \quad e \\
\text{REAL(8)} & \quad d \\
\text{e} & \quad = 123456.7 \\
\text{d} & \quad = 123456.7D0 \\
! \text{DPROD (e,e) returns 15241557546.4944} \\
! \text{DPROD (d,d) returns 15241556774.8899992813874268904328}
\end{align*}
\]

**DRAND, DRANDM**

*Portability Functions: Return double-precision random numbers in the range 0.0 through 1.0.*

**Module**

USE IFPORT

**Syntax**

result = DRAND (iflag)

result = DRANDM (iflag)

\( iflag \)

(Input) INTEGER(4). Controls the way the random number is selected.
Results
The result type is REAL(8). Return values are:

<table>
<thead>
<tr>
<th>Value of $iflag$</th>
<th>Selection process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
<tr>
<td>0</td>
<td>The next random number in the sequence is selected.</td>
</tr>
<tr>
<td>Otherwise</td>
<td>The generator is reseeded using $iflag$, then restarted, and the first random value is selected.</td>
</tr>
</tbody>
</table>

There is no difference between DRAND and DRANDM. Both functions are included to insure portability of existing code that references one or both of them.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT
REAL(8) num
INTEGER(4) f
f=1
CALL print_rand
f=0
CALL print_rand
f=22
CALL print_rand
CONTAINS
  SUBROUTINE print_rand
    num = drand(f)
    print *, 'f= ',f,':',num
  END SUBROUTINE
END

• C to D
RANGET

DREAL

Elemental Intrinsic Function (Specific):
Converts the real part of a double complex argument to double-precision type. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax
result = DREAL (a)

a  (Input) Must be of type double complex (COMPLEX(8) or COMPLEX*16).

Results
The result type is double precision real (REAL(8) or REAL*8).

Example
DREAL ((2.0d0, 3.0d0)) has the value 2.0d0.

See Also
• C to D
• REAL
DSHIFTL

Elemental Intrinsic Function (Specific): Selects the left 64 bits after shifting a 128-bit integer value to the left. This function cannot be passed as an actual argument.

Syntax

\[
\text{result} = \text{DSHIFTL}(\text{ileft}, \text{iright}, \text{ishift})
\]

\(\text{ileft}\) (Input) INTEGER(8).
\(\text{iright}\) (Input) INTEGER(8).
\(\text{ishift}\) (Input) INTEGER(8). Must be nonnegative and less than or equal to 64. This is the shift count.

Results

The result type is INTEGER(8). The result value is the 64-bit value starting at bit 128 - \text{ishift} of the 128-bit concatenation of the values of \text{ileft} and \text{iright}.

Example

Consider the following:

\[
\begin{align*}
\text{INTEGER(8)} & \text{ ILEFT / Z'111122221111222' /} \\
\text{INTEGER(8)} & \text{ IRIGHT / Z'FFFFFFFFFFFFF' /} \\
\text{PRINT *, DSHIFTL (ILEFT, IRIGHT, 16_8) ! prints 1306643199093243919}
\end{align*}
\]

DSHIFTR

Elemental Intrinsic Function (Specific): Selects the left 64 bits after shifting a 128-bit integer value to the right. This function cannot be passed as an actual argument.

Syntax

\[
\text{result} = \text{DSHIFTR}(\text{ileft}, \text{iright}, \text{ishift})
\]

\(\text{ileft}\) (Input) INTEGER(8).
\(\text{iright}\) (Input) INTEGER(8).
ishift  (Input) INTEGER(8). Must be nonnegative and less than or equal to 64. This is the shift count.

Results
The result type is INTEGER(8). The result value is the 64-bit value starting at bit 64 + ishift of the 128-bit concatenation of the values of ileft and iright.

Example
Consider the following:

```
INTEGER(8) ILEFT / Z'111122221111222' /  
INTEGER(8) IRIGHT / Z'FFFFFFFFFFFFFF' /  
PRINT *, DSHIFTR (ILEFT, IRIGHT, 16_8) ! prints 1306606910610341887
```

DTIME

**Portability Function:** Returns the elapsed CPU time since the start of program execution when first called, and the elapsed execution time since the last call to DTIME thereafter.

**Module**

USE IFPORT

**Syntax**

```
result = DTIME (tarray)
```

*tarray*  
(Output) REAL(4). A rank one array with two elements:

- *tarray*(1) - Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code.
- *tarray*(2) - Elapsed system time, which is time spent executing privileged code (code in the Windows Executive).

**Results**

The result type is REAL(4). The result is the total CPU time, which is the sum of *tarray*(1) and *tarray*(2). If an error occurs, -1 is returned.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
REAL(4) I, TA(2)
I = DTIME(TA)
write(*,*) 'Program has been running for', I, 'seconds.'
write(*,*) 'This includes', TA(1), 'seconds of user time and', &
& TA(2), 'seconds of system time.'

E to F

ELEMENTAL
Keyword: Asserts that a user-defined procedure is a restricted form of pure procedure. This is a Fortran 95 feature.

Description
To specify an elemental procedure, use this keyword in a FUNCTION or SUBROUTINE statement. An explicit interface must be visible to the caller of an ELEMENTAL procedure. An elemental procedure can be passed an array, which is acted upon one element at a time. For functions, the result must be scalar; it cannot have the POINTER or ALLOCATABLE attribute. Dummy arguments have the following restrictions:
• They must be scalar.
• They cannot have the POINTER or ALLOCATABLE attribute.
• They (or their subobjects) cannot appear in a specification expression except as an argument to one of the intrinsic functions BIT_SIZE, LEN, KIND, or the numeric inquiry functions.
• They cannot be *.
• They cannot be dummy procedures.

If the actual arguments are all scalar, the result is scalar. If the actual arguments are array valued, the values of the elements (if any) of the result are the same as if the function or subroutine had been applied separately, in any order, to corresponding elements of each array actual argument.

Elemental procedures are pure procedures and all rules that apply to pure procedures also apply to elemental procedures.

Example
Consider the following:

MIN (A, 0, B) ! A and B are arrays of shape (S, T)

In this case, the elemental reference to the MIN intrinsic function is an array expression whose elements have the following values:

MIN (A(I,J), 0, B(I,J)), I = 1, 2, ..., S, J = 1, 2, ..., T

• Optional Arguments

ELLIPSE, ELLIPSE_W (W*32, W*64)

Graphics Functions: Draw a circle or an ellipse using the current graphics color.

Module
USE IFQWIN

Syntax
result = ELLIPSE (control,x1,y1,x2,y2)
result = ELLIPSE_W (control,wx1,wy1,wx2,wy2)
control (Input) INTEGER(2). Fill flag. Can be one of the following symbolic constants:

- $GFILLINTERIOR - Fills the figure using the current color and fill mask.
- $GBORDER - Does not fill the figure.

x1, y1 (Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

x2, y2 (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

wx1, wy1 (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

wx2, wy2 (Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

**Results**

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the ellipse is clipped or partially out of bounds, the ellipse is considered successfully drawn, and the return is 1. If the ellipse is drawn completely out of bounds, the return is 0.

The border is drawn in the current color and line style.

When you use ELLIPSE, the center of the ellipse is the center of the bounding rectangle defined by the viewport-coordinate points (x1, y1) and (x2, y2). When you use ELLIPSE_W, the center of the ellipse is the center of the bounding rectangle defined by the window-coordinate points (wx1, wy1) and (wx2, wy2). If the bounding-rectangle arguments define a point or a vertical or horizontal line, no figure is drawn.

The control option given by $GFILLINTERIOR is equivalent to a subsequent call to the FLOODFILLRGB function using the center of the ellipse as the start point and the current color (set by SETCOLORRGB) as the boundary color.

**NOTE.** The ELLIPSE routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Ellipse routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Ellipse. For more information, see *Building Applications*: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines.
**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

This program draws the shape shown below.

```fortran
! compile as QuickWin or Standard Graphics application
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80;  y1 = 50
x2 = 240; y2 = 150
dummy = ELLIPSE( $GFILLINTERIOR, x1, y1, x2, y2 )
END
```

ELSE Statement
See IF Construct.

ELSE Directive
See IF Directive Construct.

ELSEIF Directive
See IF Directive Construct.

ELSE IF
See IF Construct.

ELSE WHERE
Statement: Marks the beginning of an ELSE WHERE block within a WHERE construct.

Syntax

\[
\begin{align*}
  \text{name:} & \text{WHERE (mask-expr1)} \\
  & \quad [\text{where-body-stmt}] \ldots \\
  [\text{ELSE WHERE (mask-expr2) [name]}] \\
  & \quad [\text{where-body-stmt}] \ldots \\
  [\text{ELSE WHERE [name]}] \\
  & \quad [\text{where-body-stmt}] \ldots \\
  \text{END WHERE [name]} \\
\end{align*}
\]

- \text{name} is the name of the WHERE construct.
- \text{mask-expr1, mask-expr2} are logical array expressions (called mask expressions).
- \text{where-body-stmt} is one of the following:
  - An assignment statement of the form: array variable = array expression.
    The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.
  - A WHERE statement or construct
Description

Every assignment statement following the `ELSE WHERE` is executed as if it were a `WHERE` statement with `".NOT. mask-expr1"`. If `ELSE WHERE` specifies `"mask-expr2"`, it is executed as `"(.NOT. mask-expr1) .AND. mask-expr2"` during the processing of the `ELSE WHERE` statement.

Example

```
WHERE (pressure <= 1.0)
  pressure = pressure + inc_pressure
  temp = temp - 5.0
ELSEWHERE
  raining = .TRUE.
END WHERE
```

The variables `temp`, `pressure`, and `raining` are all arrays.

See Also
- E to F
- WHERE

**ENCODE**

**Statement**: Translates data from internal (binary) form to character form. It is comparable to using internal files in formatted sequential WRITE statements.

**Syntax**

```
ENCODE (c, f, b[, IOSTAT=i-var] [, ERR=label]) [io-list]
```

- `c` is a scalar integer expression. It is the number of characters to be translated to internal form.
- `f` is a format identifier. An error occurs if more than one record is specified.
- `b` is a scalar or array reference. If `b` is an array reference, its elements are processed in the order of subscript progression. `b` contains the characters to be translated to internal form.
**i-var**
Is a scalar integer variable that is defined as a positive integer if an error occurs and as zero if no error occurs (see I/O Status Specifier).

**label**
Is the label of an executable statement that receives control if an error occurs.

**io-list**
Is an I/O list. An I/O list is either an implied-DO list or a simple list of variables (except for assumed-size arrays). The list contains the data to be translated to character form. The interaction between the format specifier and the I/O list is the same as for a formatted I/O statement.

The number of characters that the ENCODE statement can translate depends on the data type of \( b \). For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.

**Example**
Consider the following:

```fortran
DIMENSION K(3)
CHARACTER*12 A,B
DATA A/'123456789012'/
ENCOD(12,100,A) K
100 FORMAT(3I4)
ENCOD(12,100,B) K(3), K(2), K(1)
```

The 12 characters are stored in array K:

- \( K(1) = 1234 \)
- \( K(2) = 5678 \)
- \( K(3) = 9012 \)

The ENCODE statement translates the values \( K(3), K(2), \) and \( K(1) \) to character form and stores the characters in the character variable B:

\( B = '901256781234' \)

• DECODE

END

Statement: Marks the end of a program unit. It takes one of the following forms:

Syntax
END [PROGRAM [program-name]]
END [FUNCTION [function-name]]
END [SUBROUTINE [subroutine-name]]
END [MODULE [module-name]]
END [BLOCK DATA [block-data-name]]

For internal procedures and module procedures, you must specify the FUNCTION and SUBROUTINE keywords in the END statement; otherwise, the keywords are optional.

In main programs, function subprograms, and subroutine subprograms, END statements are executable and can be branch target statements. If control reaches the END statement in these program units, the following occurs:

• In a main program, execution of the program terminates.
• In a function or subroutine subprogram, a RETURN statement is implicitly executed.

The END statement cannot be continued in a program unit, and no other statement in the program unit can have an initial line that appears to be the program unit END statement.

The END statements in a module or block data program unit are nonexecutable.
Example
    C An END statement must be the last statement in a program
    C unit:
        PROGRAM MyProg
        WRITE (*, '("Hello, world!")')
        END

    C An example of a named subroutine
    C
        SUBROUTINE EXT1 (X,Y,Z)
            Real, Dimension (100,100) :: X, Y, Z
        END SUBROUTINE EXT1

See Also
• E to F
• Program Units and Procedures
• Branch Statements

END DO
Statement: Marks the end of a DO or DO WHILE
loop.

Syntax
    END DO

Description
There must be a matching END DO statement for every DO or DO WHILE statement that does not contain a label reference.

An END DO statement can terminate only one DO or DO WHILE statement. If you name the DO or DO WHILE statement, the END DO statement can specify the same name.
Example
The following examples both produce the same output:

```fortran
DO ivar = 1, 10
   PRINT ivar
END DO
ivar = 0
do2: DO WHILE (ivar .LT. 10)
   ivar = ivar + 1
   PRINT ivar
END DO do2
```

See Also
- E to F
- DO
- DO WHILE
- CONTINUE

ENDIF Directive
See IF Directive Construct.

END IF
See IF Construct.

ENDFILE

Statement: For sequential files, writes an end-of-file record to the file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.

Syntax
It can have either of the following forms:

```fortran
ENDFILE ([UNIT=] io-unit[, ERR= label] [, IOSTAT=i-var])
ENDFILE io-unit
```
**io-unit**
(Input) Is an external unit specifier.

**label**
Is the label of the branch target statement that receives control if an error occurs.

**i-var**
(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

**Description**
If the unit specified in the ENDFILE statement is not open, the default file is opened for unformatted output.

An end-of-file record can be written only to files with sequential organization that are accessed as formatted-sequential or unformatted-segmented sequential files. An ENDFILE performed on a direct access file always truncates the file.

End-of-file records should not be written in files that are read by programs written in a language other than Fortran.

**NOTE.** If you use compiler option vms and an ENDFILE is performed on a sequential unit, an actual one byte record containing a CTRL+Z is written to the file. If this option is not specified, an internal ENDFILE flag is set and the file is truncated. The option does not affect ENDFILE on relative files; such files are truncated.

If a parameter of the ENDFILE statement is an expression that calls a function, that function must not cause an I/O statement or the EOF intrinsic function to be executed, because unpredictable results can occur.

**Example**

The following statement writes an end-of-file record to I/O unit 2:

```fortran
ENDFILE 2
```

Suppose the following statement is specified:

```fortran
ENDFILE (UNIT=9, IOSTAT=IOS, ERR=10)
```

An end-of-file record is written to the file connected to unit 9. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.
The following shows another example:

```
WRITE (6, *) x
ENDFILE 6
REWIND 6
READ (6, *) y
```

**END FORALL**

*Statement:* Marks the end of a FORALL construct.  
See [FORALL](#).

**END INTERFACE**

*Statement:* Marks the end of an INTERFACE block.  
See [INTERFACE](#).

**MAP...END MAP**

*Statement:* Specifies mapped field declarations that are part of a UNION declaration within a STRUCTURE declaration. See [STRUCTURE](#).

**Example**

```fortran
UNION
  MAP
    CHARACTER*20 string
  END MAP
  MAP
    INTEGER*2 number(10)
  END MAP
END UNION
UNION
  MAP
    RECORD /Cartesian/ xcoord, ycoord
  END MAP
  MAP
    RECORD /Polar/ length, angle
  END MAP
END UNION
```

2608
SELECT CASE...END SELECT

**Statement:** Transfers program control to a selected block of statements according to the value of a controlling expression. **CASE.**

**Example**

```plaintext
CHARACTER*1 cmdchar

... Files: SELECT CASE (cmdchar)

  CASE ('0')
      WRITE (*, *) "Must retrieve one to nine files"
  CASE ('1':'9')
      CALL RetrieveNumFiles (cmdchar)
  CASE ('A', 'a')
      CALL AddEntry
  CASE ('D', 'd')
      CALL DeleteEntry
  CASE ('H', 'h')
      CALL Help
  CASE DEFAULT
      WRITE (*, *) "Command not recognized; please re-enter"

END SELECT Files
```

STRUCTURE...END STRUCTURE

**Statement:** Defines the field names, types of data within fields, and order and alignment of fields within a record structure. Fields and structures can be initialized, but records cannot be initialized.

**Syntax**

```plaintext
STRUCTURE [/structure-name/] [field-namelist]
```
FIELD-DECLARATION

[FIELD-DECLARATION]

. . .

[FIELD-DECLARATION]

END STRUCTURE

STRUCTURE-NAME

Is the name used to identify a structure, enclosed by slashes. Subsequent RECORD statements use the structure name to refer to the structure. A structure name must be unique among structure names, but structures can share names with variables (scalar or array), record fields, PARAMETER constants, and common blocks. Structure declarations can be nested (contain one or more other structure declarations). A structure name is required for the structured declaration at the outermost level of nesting, and is optional for the other declarations nested in it. However, if you wish to reference a nested structure in a RECORD statement in your program, it must have a name.

Structure, field, and record names are all local to the defining program unit. When records are passed as arguments, the fields in the defining structures within the calling and called subprograms must match in type, order, and dimension.

FIELD-NAMELIST

Is a list of fields having the structure of the associated structure declaration. A field namelist is allowed only in nested structure declarations.

FIELD-DECLARATION

Also called the declaration body. A field-declaration consists of any combination of the following:

- **Type declarations**
  These are ordinary Fortran data type declarations.

- **Substructure declarations**
  A field within a structure can be a substructure composed of atomic fields, other substructures, or a combination of both.

- **Union declarations**
  A union declaration is composed of one or more mapped field declarations.

- **PARAMETER statements**
PARAMETER statements can appear in a structure declaration, but cannot be given a data type within the declaration block.

Type declarations for PARAMETER names must precede the PARAMETER statement and be outside of a STRUCTURE declaration, as follows:

```fortran
INTEGER*4 P
STRUCTURE /ABC/
  PARAMETER (P=4)
  REAL*4 F
END STRUCTURE
REAL*4 A(P)
```

The Fortran 90 derived type replaces STRUCTURE and RECORD constructs, and should be used in writing new code. See Derived Data Types.

Unlike type declaration statements, structure declarations do not create variables. Structured variables (records) are created when you use a RECORD statement containing the name of a previously declared structure. The RECORD statement can be considered as a kind of type declaration statement. The difference is that aggregate items, not single items, are being defined.

Within a structure declaration, the ordering of both the statements and the field names within the statements is important, because this ordering determines the order of the fields in records.

In a structure declaration, each field offset is the sum of the lengths of the previous fields, so the length of the structure is the sum of the lengths of its fields. The structure is packed; you must explicitly provide any alignment that is needed by including, for example, unnamed fields of the appropriate length.

By default, fields are aligned on natural boundaries; misaligned fields are padded as necessary. To avoid padding of records, you should lay out structures so that all fields are naturally aligned.

To pack fields on arbitrary byte boundaries, you must specify a compiler option. You can also specify alignment for fields by using the OPTIONS or PACK general directive.

A field name must not be the same as any intrinsic or user-defined operator (for example, EQ cannot be used as a field name).
Compatibility

An item can be a RECORD statement that references a previously defined structure type:

```fortran
STRUCTURE /full_address/
    RECORD /full_name/ personsname
    RECORD /address/ ship_to
    INTEGER*1 age
    INTEGER*4 phone
END STRUCTURE
```

You can specify a particular item by listing the sequence of items required to reach it, separated by a period (.). Suppose you declare a structure variable, `shippingaddress`, using the `full_address` structure defined in the previous example:

```fortran
RECORD /full_address/ shippingaddress
```

In this case, the `age` item would then be specified by `shippingaddress.age`, the first name of the receiver by `shippingaddress.personsname.first_name`, and so on.

In the following example, the declaration defines a structure named `APPOINTMENT`. `APPOINTMENT` contains the structure `DATE(field APP_DATE)` as a substructure. It also contains a substructure named `TIME(field APP_TIME, an array)`, a `CHARACTER*20 array named APP_MEMO`, and a `LOGICAL*1 field named APP_FLAG`.

```fortran
STRUCTURE /DATE/        
    INTEGER*1 DAY, MONTH
    INTEGER*2 YEAR
END STRUCTURE

STRUCTURE /APPOINTMENT/  
    RECORD /DATE/   APP_DATE
    STRUCTURE /TIME/ APP_TIME (2)
        INTEGER*1 HOUR, MINUTE
    END STRUCTURE
    CHARACTER*20 APP_MEMO (4)
    LOGICAL*1 APP_FLAG
END STRUCTURE
```
The length of any instance of structure **APPOINTMENT** is 89 bytes.
The following figure shows the memory mapping of any record or record array element with the structure APPOINTMENT.
Figure 54: Memory Map of Structure APPOINTMENT
(byte offset)
0  field DAY of field APP_DATE
1  field MONTH of field APP_DATE
2  field YEAR of field APP_DATE
3
4  field HOUR of field APP_TIME(1)
5  field MINUTE of field APP_TIME(1)
6  field HOUR of field APP_TIME(2)
7  field MINUTE of field APP_TIME(2)
8  field APP_MEMO(1)
   ...
28  field APP_MEMO(2)
   ...
48  field APP_MEMO(3)
   ...
68  field APP_MEMO(4)
   ...
88  field APP_FLAG
89

**TYPE Statement (Derived Types)**

**Statement:** Declares a variable to be a derived type. It specifies the name of the user-defined type and the types of its components.

**Syntax**

```
TYPE [[: , type-attr-spec-list]] :: ] name

component-definition
  [component-definition]. . .

END TYPE [ name ]
```

- `type-attr-spec-list` is `access-spec` or `BIND (C)`.
- `access-spec` is the PUBLIC or PRIVATE keyword. The keyword can only be specified if the derived-type definition is in the specification part of a module.
- `name` is the name of the derived data type. It must not be the same as the name of any intrinsic type, or the same as the name of a derived type that can be accessed from a module.
- `component-definition` is one or more type declaration statements defining the component of derived type. The first component definition can be preceded by an optional PRIVATE or SEQUENCE statement. (Only one PRIVATE or SEQUENCE statement can appear in a given derived-type definition.)
If SEQUENCE is present, all derived types specified in component definitions must be sequence types.

A component definition takes the following form:

\[
\text{type}[,\text{attr}]::\text{component}[(\text{a-spec})][\text{char-len}][\text{init-ex}]
\]

- **type** is a type specifier. It can be an intrinsic type or a previously defined derived type. (If the POINTER attribute follows this specifier, the type can also be any accessible derived type, including the type being defined.)
- **attr** is an optional POINTER attribute for a pointer component, or an optional DIMENSION or ALLOCATABLE attribute for an array component. You cannot specify both the ALLOCATABLE and POINTER attribute. If DIMENSION is specified, it can be followed by an array specification. Each attribute can only appear once in a given component-definition.
- **component** is the name of the component being defined.
- **a-spec** is an optional array specification, enclosed in parentheses. If POINTER or ALLOCATABLE is specified, the array is deferred shape; otherwise, it is explicit shape. In an explicit-shape specification, each bound must be a constant scalar integer expression. If the array bounds are not specified here, they must be specified following the DIMENSION attribute.
- **char-len** is an optional scalar integer literal constant; it must be preceded by an asterisk (*). This parameter can only be specified if the component is of type CHARACTER.
- **init-ex** is an initialization expression, or for pointer components, \(
\Rightarrow \text{NULL( )}\). This is a Fortran 95 feature.
If `init-ex` is specified, a double colon must appear in the component definition. The equals assignment symbol (=) can only be specified for nonpointer components. The initialization expression is evaluated in the scoping unit of the type definition.

**Description**

If a name is specified following the `END TYPE` statement, it must be the same name that follows `TYPE` in the derived type statement.

A derived type can be defined only once in a scoping unit. If the same derived-type name appears in a derived-type definition in another scoping unit, it is treated independently.

A component name has the scope of the derived-type definition only. Therefore, the same name can be used in another derived-type definition in the same scoping unit.

Two data entities have the same type if they are both declared to be of the same derived type (the derived-type definition can be accessed from a module or a host scoping unit).

If the entities are in different scoping units, they can also have the same derived type if they are declared with reference to different derived-type definitions, and if both derived-type definitions have all of the following:

- The same name
- A `SEQUENCE` statement (they both have sequence type)
- Components that agree in name, order, and attributes; components cannot be private

If `BIND (C)` is specified, the following rules apply:

- The derived type cannot be a `SEQUENCE` type.
- The derived type must have type parameters.
- Each component of the derived type must be a nonpointer, nonallocatable data component with interoperable type and type parameters.
Example

!  DERIVED.F90
!  Define a derived-type structure,
!  type variables, and assign values

TYPE member
  INTEGER age
  CHARACTER (LEN = 20) name
END TYPE member

TYPE (member) :: george
TYPE (member) :: ernie

george = member( 33, 'George Brown' )
ernie%age = 56
ernie%name = 'Ernie Brown'

WRITE (*,*) george
WRITE (*,*) ernie

END
The following shows another example of a derived type:

```fortran
TYPE mem_name
  SEQUENCE
  CHARACTER (LEN = 20) lastn
  CHARACTER (LEN = 20) firstn
  CHARACTER (len = 3) cos ! this works because COS is a component name
END TYPE mem_name

TYPE member
  TYPE (mem_name) :: name
  SEQUENCE
  INTEGER age
  CHARACTER (LEN = 20) specialty
END TYPE member
```

In the following example, `a` and `b` are both variable arrays of derived type `pair`:

```fortran
TYPE (pair)
  INTEGER i, j
END TYPE

TYPE (pair), DIMENSION (2, 2) :: a, b(3)
```
The following example shows how you can use derived-type objects as components of other derived-type objects:

```fortran
TYPE employee_name
  CHARACTER(25) last_name
  CHARACTER(15) first_name
END TYPE

TYPE employee_addr
  CHARACTER(20) street_name
  INTEGER(2) street_number
  INTEGER(2) apt_number
  CHARACTER(20) city
  CHARACTER(2) state
  INTEGER(4) zip
END TYPE

Objects of these derived types can then be used within a third derived-type specification, such as:

```fortran
TYPE employee_data
  TYPE (employee_name) :: name
  TYPE (employee_addr) :: addr
  INTEGER(4) telephone
  INTEGER(2) date_of_birth
  INTEGER(2) date_of_hire
  INTEGER(2) social_security(3)
  LOGICAL(2) married
  INTEGER(2) dependents
END TYPE
```

**See Also**

- C to D
- E to F
Statements: Define a data area that can be shared intermittently during program execution by one or more fields or groups of fields. A union declaration must be within a structure declaration.

Syntax

Each unique field or group of fields is defined by a separate map declaration.

UNION

map-declaration
map-declaration
[map-declaration]
...
[map-declaration]

END UNION

map-declaration Takes the following form:

MAP

field-declaration
field-declaration

..

field-declaration

END MAP

field-declaration Is a structure declaration or RECORD statement contained within a union declaration, a union declaration contained within a union declaration, or the declaration of a data field (having a data type) within a union. It can be of any intrinsic or derived type.

As with normal Fortran type declarations, data can be initialized in field declaration statements in union declarations. However, if fields within multiple map declarations in a single union are initialized, the data declarations are initialized in the order in which the statements appear. As a result, only the final initialization takes effect and all of the preceding initializations are overwritten.

The size of the shared area established for a union declaration is the size of the largest map defined for that union. The size of a map is the sum of the sizes of the fields declared within it.

Manipulating data by using union declarations is similar to using EQUIVALENCE statements. The difference is that data entities specified within EQUIVALENCE statements are concurrently associated with a common storage location and the data residing there; with union declarations you can use one discrete storage location to alternately contain a variety of fields (arrays or variables).

With union declarations, only one map declaration within a union declaration can be associated at any point in time with the storage location that they share. Whenever a field within another map declaration in the same union declaration is referenced in your program, the fields in the prior map declaration become undefined and are succeeded by the fields in the map declaration containing the newly referenced field.
Example

In the following example, the structure WORDS_LONG is defined. This structure contains a union declaration defining two map fields. The first map field consists of three INTEGER*2 variables (WORD_0, WORD_1, and WORD_2), and the second, an INTEGER*4 variable, LONG:

```plaintext
STRUCTURE /WORDS_LONG/
    UNION
        MAP
            INTEGER*2 WORD_0, WORD_1, WORD_2
        END MAP
        MAP
            INTEGER*4 LONG
        END MAP
    END UNION
END STRUCTURE
```

The length of any record with the structure WORDS_LONG is 6 bytes. The following figure shows the memory mapping of any record with the structure WORDS_LONG:

**Figure 55: Memory Map of Structure WORDS_LONG**
In the following example, note how the first 40 characters in the string2 array are overlayed on 4-byte integers, while the remaining 20 are overlayed on 2-byte integers:

```
UNION
  MAP
    CHARACTER*20 string1, CHARACTER*10 string2(6)
  END MAP
  MAP
    INTEGER*2 number(10), INTEGER*4 var(10), INTEGER*2 + datum(10)
  END MAP
END UNION
```

See Also
- E to F
- T to Z
- STRUCTURE...END STRUCTURE
- Record Structures

**END WHERE**

**Statement:** Marks the end of a WHERE block. See WHERE.

**Example**
```
WHERE (pressure <= 1.0)
  pressure = pressure + inc_pressure
  temp = temp - 5.0
ELSEWHERE
  raining = .TRUE.
END WHERE
```

Note that the variables `temp`, `pressure`, and `raining` are all arrays.
ENTRY

**Statement:** Provides one or more entry points within a subprogram. It is not executable and must precede any CONTAINS statement (if any) within the subprogram.

**Syntax**

ENTRY name[ ( [d-arg[,d-arg]...] ) [RESULT (r-name)] ]

- `name` (Optional) Is the name of an entry point. If RESULT is specified, this entry name must not appear in any specification statement in the scoping unit of the function subprogram.
- `d-arg` (Optional) Is a dummy argument. The dummy argument can be an alternate return indicator (*) if the ENTRY statement is within a subroutine subprogram.
- `r-name` (Optional) Is the name of a function result. This name must not be the same as the name of the entry point, or the name of any other function or function result. This parameter can only be specified for function subprograms.

**Description**

ENTRY statements can only appear in external procedures or module procedures.

An ENTRY statement must not appear in a CASE, DO, IF, FORALL, or WHERE construct, or a nonblock DO loop.

When the ENTRY statement appears in a subroutine subprogram, it is referenced by a CALL statement. When the ENTRY statement appears in a function subprogram, it is referenced by a function reference.

An entry name within a function subprogram can appear in a type declaration statement.
Within the subprogram containing the ENTRY statement, the entry name must not appear as a dummy argument in the FUNCTION or SUBROUTINE statement, and it must not appear in an EXTERNAL or INTRINSIC statement. For example, neither of the following are valid:

(1) SUBROUTINE SUB(E)
    ENTRY E
    ...

(2) SUBROUTINE SUB
    EXTERNAL E
    ENTRY E
    ...

The procedure defined by an ENTRY statement can reference itself if the function or subroutine was defined as RECURSIVE.

Dummy arguments can be used in ENTRY statements even if they differ in order, number, type and kind parameters, and name from the dummy arguments used in the FUNCTION, SUBROUTINE, and other ENTRY statements in the same subprogram. However, each reference to a function, subroutine, or entry must use an actual argument list that agrees in order, number, and type with the dummy argument list in the corresponding FUNCTION, SUBROUTINE, or ENTRY statement.

Dummy arguments can be referred to only in executable statements that follow the first SUBROUTINE, FUNCTION, or ENTRY statement in which the dummy argument is specified. If a dummy argument is not currently associated with an actual argument, the dummy argument is undefined and cannot be referenced. Arguments do not retain their association from one reference of a subprogram to another.
Example
C This fragment writes a message indicating
C whether num is positive or negative
   IF (num .GE. 0) THEN
      CALL Sign
   ELSE
      CALL Negative
   END IF
   ...
END
SUBROUTINE Sign
   WRITE (*, *) 'It''s positive.'
   RETURN
ENTRY Negative
   WRITE (*, *) 'It''s negative.'
   RETURN
END SUBROUTINE

EOF
Inquiry Intrinsic Function (Generic): Checks whether a file is at or beyond the end-of-file record.

Syntax
result = EOF (unit)
unit (Input) Must be of type integer. It represents a unit specifier corresponding to an open file. It cannot be zero unless you have reconnected unit zero to a unit other than the screen or keyboard.

Results

The result type is default logical. The value of the result is .TRUE. if the file connected to unit is at or beyond the end-of-file record; otherwise, .FALSE..
**Example**

! Creates a file of random numbers, reads them back

```fortran
REAL x, total
INTEGER count
OPEN (1, FILE = 'TEST.DAT')
DO I = 1, 20
   CALL RANDOM_NUMBER(x)
   WRITE (1, '(F6.3)') x * 100.0
END DO
CLOSE(1)
OPEN (1, FILE = 'TEST.DAT')
DO WHILE (.NOT. EOF(1))
   count = count + 1
   READ (1, *) value
   total = total + value
END DO
100 IF ( count .GT. 0) THEN
   WRITE (*,*) 'Average is: ', total / count
ELSE
   WRITE (*,*) 'Input file is empty '
END IF
STOP
END
```

**See Also**
- E to F
- ENDFILE
- BACKSPACE
- REWIND
**EOSHIFT**

**Transformational Intrinsic Function (Generic):**
Performs an end-off shift on a rank-one array, or performs end-off shifts on all the complete rank-one sections along a given dimension of an array of rank two or greater. Elements are shifted off at one end of a section and copies of a boundary value are filled in at the other end. Different sections can have different boundary values and can be shifted by different amounts and in different directions.

**Syntax**

```
result = EOSHIFT (array, shift [,boundary], dim)
```

- `array` (Input) Must be an array (of any data type).
- `shift` (Input; optional) Must have the same type and kind parameters as `array`. It must be a scalar or an array with a rank that is one less than `array`, and shape `(d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n)`, where `(d_1, d_2, ..., d_n)` is the shape of `array`.
- `boundary` (Input; optional) Must have the same type and kind parameters as `array`. It must be a scalar or an array with a rank that is one less than `array`, and shape `(d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n)`. The `boundary` specifies a value to replace spaces left by the shifting procedure. If `boundary` is not specified, it is assumed to have the following default values (depending on the data type of `array`):

<table>
<thead>
<tr>
<th><code>array Type</code></th>
<th><code>boundary Value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>0</td>
</tr>
<tr>
<td>Real</td>
<td>0.0</td>
</tr>
<tr>
<td>Complex</td>
<td>(0.0, 0.0)</td>
</tr>
<tr>
<td>Logical</td>
<td>false</td>
</tr>
<tr>
<td>Character(len)</td>
<td><code>len</code> blanks</td>
</tr>
</tbody>
</table>
**dim**

(Input; optional) Must be a scalar integer with a value in the range 1 to n, where n is the rank of array. If dim is omitted, it is assumed to be 1.

**Results**

The result is an array with the same type and kind parameters, and shape as array.

If array has rank one, the same shift is applied to each element. If an element is shifted off one end of the array, the boundary value is placed at the other end the array.

If array has rank greater than one, each section (s₁, s₂, ..., s_{dim-1}, , s_{dim+1}, ..., sₙ) of the result is shifted as follows:

- By the value of shift, if shift is scalar
- According to the corresponding value in shift(s₁, s₂, ..., s_{dim-1}, s_{dim+1}, ..., sₙ), if shift is an array

If an element is shifted off one end of a section, the boundary value is placed at the other end of the section.

The value of shift determines the amount and direction of the end-off shift. A positive shift value causes a shift to the left (in rows) or up (in columns). A negative shift value causes a shift to the right (in rows) or down (in columns).

**Example**

V is the array (1, 2, 3, 4, 5, 6).

EOSHIFT (V, SHIFT=2) shifts the elements in V to the left by 2 positions, producing the value (3, 4, 5, 6, 0, 0). 1 and 2 are shifted off the beginning and two elements with the default BOUNDARY value are placed at the end.

EOSHIFT (V, SHIFT= -3, BOUNDARY= 99) shifts the elements in V to the right by 3 positions, producing the value (99, 99, 99, 1, 2, 3). 4, 5, and 6 are shifted off the end and three elements with BOUNDARY value 99 are placed at the beginning.

M is the character array

```
[ 1 2 3 ]
[ 4 5 6 ]
[ 7 8 9 ].
```
EOSHIFT (M, SHIFT = 1, BOUNDARY = '*', DIM = 2) produces the result

\[
\begin{bmatrix}
2 & 3 & * \\
5 & 6 & * \\
8 & 9 & *
\end{bmatrix}
\]

Each element in rows 1, 2, and 3 is shifted to the left by 1 position. This causes the first element in each row to be shifted off the beginning, and the BOUNDARY value to be placed at the end.

EOSHIFT (M, SHIFT = -1, DIM = 1) produces the result

\[
\begin{bmatrix}
0 & 0 & 0 \\
1 & 2 & 3 \\
4 & 5 & 6
\end{bmatrix}
\]

Each element in columns 1, 2, and 3 is shifted down by 1 position. This causes the last element in each column to be shifted off the end and the BOUNDARY value to be placed at the beginning.

EOSHIFT (M, SHIFT = (/1, -1, 0/), BOUNDARY = (/ '*', '?', '/' /), DIM = 2) produces the result

\[
\begin{bmatrix}
2 & 3 & * \\
? & 4 & 5 \\
7 & 8 & 9
\end{bmatrix}
\]

Each element in row 1 is shifted to the left by 1 position, causing the first element to be shifted off the beginning and the BOUNDARY value * to be placed at the end. Each element in row 2 is shifted to the right by 1 position, causing the last element to be shifted off the end and the BOUNDARY value ? to be placed at the beginning. No element in row 3 is shifted at all, so the specified BOUNDARY value is not used.
The following shows another example:

```
INTEGER shift(3)
CHARACTER(1) array(3, 3), AR1(3, 3)
array = RESHAPE ((/'A', 'D', 'G', 'B', 'E', 'H', &
                  'C', 'F', 'I'/), (/3,3/))
! array is A B C
! D E F
! G H I
shift = (/ -1, 1, 0/)
AR1 = EOSHIFT (array, shift, BOUNDARY = (/ '*', '?', '#'/), DIM= 2)
! returns * A B
! E F ?
! G H I
```

- CSHIFT
- ISHFT
- ISHFTC
- TRANSPOSE

**EPSILON**

Inquiry Intrinsic Function (Generic): Returns a positive model number that is almost negligible compared to unity in the model representing real numbers.

**Syntax**

```
result = EPSILON (x)
```

- `x` (Input) Must be of type real; it can be scalar or array valued.
Results

The result is a scalar of the same type and kind parameters as \( x \). The result has the value \( b^{1-p} \). Parameters \( b \) and \( p \) are defined in Model for Real Data.

EPSILON makes it easy to select a \( \delta \) for algorithms (such as root locators) that search until the calculation is within \( \delta \) of an estimate. If \( \delta \) is too small (smaller than the decimal resolution of the data type), the algorithm might never halt. By scaling the value returned by EPSILON to the estimate, you obtain a \( \delta \) that ensures search termination.

Example

If \( x \) is of type REAL(4), EPSILON (X) has the value \( 2^{-23} \).

EQUIVALENCE

**Statement:** Specifies that a storage area is shared by two or more objects in a program unit. This causes total or partial storage association of the objects that share the storage area.

**Syntax**

\[
\text{EQUIVALENCE (equiv-list) [, (equiv-list)]...}
\]

**equiv-list**

Is a list of two or more variable names, array elements, or substrings, separated by commas (also called an equivalence set). If an object of derived type is specified, it must be a sequence type. Objects cannot have the TARGET attribute. Each expression in a subscript or a substring reference must be an integer initialization expression. A substring must not have a length of zero.

**Description**

The following objects cannot be specified in EQUIVALENCE statements:

- A dummy argument
- An allocatable variable
- An automatic object
- A pointer
- An object of nonsequence derived type
- A derived-type object that has an allocatable or pointer component at any level
- A component of a derived-type object
- A function, entry, or result name
- A named constant
- A structure component
- A subobject of any of the above objects
- An object with either the DLLIMPORT or DLLEXPORT attribute
- A variable with the BIND attribute
- A variable in a common block that has the BIND attribute

The EQUIVALENCE statement causes all of the entities in one parenthesized list to be allocated storage beginning at the same storage location.

If an equivalence object has the PROTECTED attribute, all of the objects in the equivalence set must have the PROTECTED attribute.

Association of objects depends on their types, as follows:

<table>
<thead>
<tr>
<th>Type of Object</th>
<th>Type of Associated Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intrinsic numeric¹ or numeric sequence</td>
<td>Can be of any of these types</td>
</tr>
<tr>
<td>Default character or character sequence</td>
<td>Can be of either of these types ²</td>
</tr>
<tr>
<td>Any other intrinsic type</td>
<td>Must have the same type and kind parameters</td>
</tr>
<tr>
<td>Any other sequence type</td>
<td>Must have the same type</td>
</tr>
</tbody>
</table>

¹Default integer, default real, double precision real, default complex, double complex, or default logical.

²The lengths do not have to be equal.
So, objects can be associated if they are of different numeric type. For example, the following is valid:

```fortran
INTEGER A(20)
REAL Y(20)
EQUIVALENCE(A, Y)
```

Objects of default character do not need to have the same length. The following example associates character variable D with the last 4 (of the 6) characters of character array F:

```fortran
CHARACTER(LEN=4) D
CHARACTER(LEN=3) F(2)
EQUIVALENCE(D, F(1)(3:n))
```

Entities having different data types can be associated because multiple components of one data type can share storage with a single component of a higher-ranked data type. For example, if you make an integer variable equivalent to a complex variable, the integer variable shares storage with the real part of the complex variable.

The same storage unit cannot occur more than once in a storage sequence, and consecutive storage units cannot be specified in a way that would make them nonconsecutive.

Intel® Fortran lets you associate character and noncharacter entities, for example:

```fortran
CHARACTER*1 char1(10)
REAL reala, realb
EQUIVALENCE (reala, char1(1))
EQUIVALENCE (realb, char1(2))
```

EQUIVALENCE statements require only the first subscript of a multidimensional array (unless the STRICT compiler directive is in effect). For example, the array declaration `var(3,3), var(4)` could appear in an EQUIVALENCE statement. The reference is to the fourth element of the array (`var(1,2)`), not to the beginning of the fourth row or column.

If you use the STRICT directive, the following rules apply to the kinds of variables and arrays that you can associate:

- If an EQUIVALENCE object is default integer, default real, double-precision real, default complex, default logical, or a sequenced derived type of all numeric or logical components, all objects in the EQUIVALENCE statement must be one of these types, though it is not necessary that they be the same type.
• If an EQUIVALENCE object is default character or a sequenced derived type of all character components, all objects in the EQUIVALENCE statement must be one of these types. The lengths do not need to be the same.

• If an EQUIVALENCE object is a sequenced derived type that is not purely numeric or purely character, all objects in the EQUIVALENCE statement must be the same derived type.

• If an EQUIVALENCE object is an intrinsic type other than the default (for example, INTEGER(1)), all objects in the EQUIVALENCE statement must be the same type and kind.

Example

The following EQUIVALENCE statement is invalid because it specifies the same storage unit for X(1) and X(2):

```fortran
REAL, DIMENSION(2) :: X
REAL :: Y
EQUIVALENCE(X(1), Y), (X(2), Y)
```

The following EQUIVALENCE statement is invalid because A(1) and A(2) will not be consecutive:

```fortran
REAL A(2)
DOUBLE PRECISION D(2)
EQUIVALENCE(A(1), D(1)), (A(2), D(2))
```

In the following example, the EQUIVALENCE statement causes the four elements of the integer array IARR to share the same storage as that of the double-precision variable DVAR:

```fortran
DOUBLE PRECISION DVAR
INTEGER(KIND=2) IARR(4)
EQUIVALENCE(DVAR, IARR(1))
```

In the following example, the EQUIVALENCE statement causes the first character of the character variables KEY and STAR to share the same storage location. The character variable STAR is equivalent to the substring KEY(1:10).

```fortran
CHARACTER KEY*16, STAR*10
EQUIVALENCE(KEY, STAR)
```
The following shows another example:

```fortran
CHARACTER name, first, middle, last
DIMENSION name(60), first(20), middle(20), last(20)
EQUIVALENCE (name(1), first(1)), (name(21), middle(1))
EQUIVALENCE (name(41), last(1))
```

Consider the following:

```fortran
CHARACTER (LEN = 4) :: a, b
CHARACTER (LEN = 3) :: c(2)
EQUIVALENCE (a, c(1)), (b, c(2))
```

This causes the following alignment:

```
1 2 3 4 5 6 7
a(1:1) a(2:2) a(3:3) a(4:4)
     b(1:1) b(2:2) b(3:3) b(4:4)
c(1)(1:1) c(1)(2:2) c(1)(3:3) c(2)(1:1) c(2)(2:2) c(2)(3:3)
```

Note that the fourth element of `a`, the first element of `b`, and the first element of `c(2)` share the same storage unit.

**ERF**

*Elemental Intrinsic Function (Generic):*

*Returns the error function of an argument.*

**Syntax**

```
result = ERF (x)
```

`x`  
(Input) Must be of type real.
Results
The result type is the same as $x$. The result is in the range -1 to 1.

ERF returns the error function of $x$ defined as follows:

$$
\frac{2}{\sqrt{\pi}} \int_{0}^{x} e^{-t^2} dt
$$

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERF</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DERF</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QERF</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example
ERF (1.0) has the value 0.842700794.

See Also
- E to F
- ERFC

ERFC

*Elemental Intrinsic Function (Generic):*

*Returns the complementary error function of an argument.*

Syntax

```
result = ERFC (x)
```

$x$  
(Input) Must be of type real.

Results
The result type is the same as $x$. The result is in the range 0 to 2.

ERFC returns $1 - \text{ERF}(x)$ and is defined as follows:
ERFC is provided because of the extreme loss of relative accuracy if ERF(x) is called for large x and the result is subtracted from 1.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERFC</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DERFC</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QERFC</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ERFC (1.0) has the value 0.1572992057.

**See Also**

- E to F
- ERF

**ERRSNS**

*Intrinsic Subroutine (Generic):* Returns information about the most recently detected I/O system error condition. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL ERRSNS ([io_err] [,sys_err] [,stat] [,unit] [,cond])
```

`io_err` (Output; Optional) Is an integer variable or array element that stores the most recent Run-Time Library error number that occurred during program execution. (For a listing of error numbers, see *Building Applications*.)

A zero indicates no error has occurred since the last call to ERRSNS or since the start of program execution.
**sys_err**  
(Output; Optional) Is an integer variable or array element that stores the most recent system error number associated with `io_err`. This code is one of the following:

- On Windows* systems, it is the value returned by `GETLASTERROR()` at the time of the error.
- On Linux* and Mac OS* X systems, it is an `errno` value. (See `errno(2)`.)

**stat**  
(Output; Optional) Is an integer variable or array element that stores a status value that occurred during program execution. This value is always set to zero.

**unit**  
(Output; Optional) Is an integer variable or array element that stores the logical unit number, if the last error was an I/O error.

**cond**  
(Output; Optional) Is an integer variable or array element that stores the actual processor value. This value is always set to zero.

If you specify INTEGER(2) arguments, only the low-order 16 bits of information are returned or adjacent data can be overwritten. Because of this, it is best to use INTEGER(4) arguments.

The saved error information is set to zero after each call to ERRSNS.

**Example**

Any of the arguments can be omitted. For example, the following is valid:

```fortran
CALL ERRSNS (SYS_ERR=I1, STAT=I2, UNIT=I4)
```

**ETIME**

*Portability Function:* On single processor systems, returns the elapsed CPU time, in seconds, of the process that calls it. On multi-core or multi-processor systems, returns the elapsed wall-clock time, in seconds.

**Module**

`USE IFPORT`

**Syntax**

```fortran
result = ETIME (array)
```
array (Output) REAL(4). Must be a rank one array with two elements:

- array(1) — Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code. On single processors, ETIME returns the elapsed CPU time, in seconds, of the process that calls it. On multiple processors, ETIME returns the elapsed wall-clock time, in seconds.

- array(2) — Elapsed system time, which is time spent executing privileged code (code in the Windows Executive) on single processors; on multiple processors, this value is zero.

Results
The result type is REAL(4). The result is the total CPU time, which is the sum of array(1) and array(2).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
REAL(4) I, TA(2)
I = ETIME(TA)
write(*,*) 'Program has used', I, 'seconds of CPU time.'
write(*,*) ' This includes', TA(1), 'seconds of user time and', &
& TA(2), 'seconds of system time.'

See Also
- E to F
- DATE_AND_TIME
EXIT Statement

Statement: Terminates execution of a DO construct.

Syntax

EXIT [name]

name (Optional) Is the name of the DO construct.

Description

The EXIT statement causes execution of the named (or innermost) DO construct to be terminated.

If a DO construct name is specified, the EXIT statement must be within the range of that construct.

Any DO variable present retains its last defined value.

An EXIT statement can be labeled, but it cannot be used to terminate a DO construct.

Example

The following example shows an EXIT statement:

LOOP_A : DO I = 1, 15
   N = N + 1
   IF (N > I) EXIT LOOP_A
END DO LOOP_A
The following shows another example:

```fortran
INTEGER numpoints, point
REAL datarray(1000), sum
sum = 0.0
DO point = 1, 1000
   sum = sum + datarray(point)
   IF (datarray(point+1) .EQ. 0.0) EXIT
END DO
```

See Also
- E to F
- DO
- DO WHILE

**EXIT Subroutine**

*Intrinsic Subroutine (Generic):* Terminates program execution, closes all files, and returns control to the operating system. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL EXIT [([status] )]
```

*status* (Output; optional) Is an integer argument you can use to specify the image exit-status value.

The exit-status value may not be accessible after program termination in some application environments.
Example

```fortran
INTEGER(4) exvalue
! all is well, exit with 1
   exvalue = 1
   CALL EXIT (exvalue)
! all is not well, exit with diagnostic -4
   exvalue = -4
   CALL EXIT (exvalue)
! give no diagnostic, just exit
   CALL EXIT ( )
```

See Also

- E to F
- END
- ABORT

EXP

*Elemental Intrinsic Function (Generic): Computes an exponential value.*

Syntax

```fortran
result = EXP (x)
```

\(x\) (Input) Must be of type real or complex.

Results

The result type is the same as \(x\). The value of the result is \(e^x\). If \(x\) is of type complex, its imaginary part is regarded as a value in radians.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXP</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DEXP</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>Specific Name</td>
<td>Argument Type</td>
<td>Result Type</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>QEXP</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
<tr>
<td>CEXP ¹</td>
<td>COMPLEX(4)</td>
<td>COMPLEX(4)</td>
</tr>
<tr>
<td>CDEXP ²</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQEXP</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

¹ The setting of compiler options specifying real size can affect CEXP.
² This function can also be specified as ZEXP.

Example

EXP (2.0) has the value 7.389056.

EXP (1.3) has the value 3.669297.

The following shows another example:

! Given initial size and growth rate,
! calculates the size of a colony at a given time.
    REAL sizei, sizef, time, rate
    sizei = 10000.0
    time = 40.5
    rate = 0.0875
    sizef = sizei * EXP (rate * time)
    WRITE (*, 100) sizef
100 FORMAT (' The final size is ', E12.6)
END

See Also
- E to F
- LOG
EXPONENT

Elemental Intrinsic Function (Generic):
Returns the exponent part of the argument when represented as a model number.

Syntax

result = EXPONENT (x)

x (Input) must be of type real.

Results

The result type is default integer. If x is not equal to zero, the result value is the exponent part of x. The exponent must be within default integer range; otherwise, the result is undefined.

If x is zero, the exponent of x is zero. For more information on the exponent part ( e) in the real model, see Model for Real Data.

Example

EXPONENT (2.0) has the value 2.

If 4.1 is a REAL(4) value, EXPONENT (4.1) has the value 3.

The following shows another example:

```
REAL(4) r1, r2
REAL(8) r3, r4
r1 = 1.0
r2 = 123456.7
r3 = 1.0D0
r4 = 123456789123456.7
write(*,*) EXPONENT(r1) ! prints 1
write(*,*) EXPONENT(r2) ! prints 17
write(*,*) EXPONENT(r3) ! prints 1
write(*,*) EXPONENT(r4) ! prints 47
END
```

EXTERNAL

**Statement and Attribute:** Allows an external or dummy procedure to be used as an actual argument. (To specify intrinsic procedures as actual arguments, use the INTRINSIC attribute.)

Syntax

The EXTERNAL attribute can be specified in a type declaration statement or an EXTERNAL statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls,]  EXTERNAL [, att-ls] :: ex-pro[, ex-pro]...
```

**Statement:**

```
EXTERNAL [:]ex-pro[, ex-pro]...
```

<table>
<thead>
<tr>
<th><strong>att-pro</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>type</strong></td>
<td>Is a data type specifier.</td>
</tr>
<tr>
<td><strong>att-ls</strong></td>
<td>Is an optional list of attribute specifiers.</td>
</tr>
<tr>
<td><strong>ex-pro</strong></td>
<td>Is the name of an external (user-supplied) procedure or dummy procedure.</td>
</tr>
</tbody>
</table>

Description

In a type declaration statement, only *functions* can be declared EXTERNAL. However, you can use the EXTERNAL statement to declare subroutines and block data program units, as well as functions, to be external.

The name declared EXTERNAL is assumed to be the name of an external procedure, even if the name is the same as that of an intrinsic procedure. For example, if SIN is declared with the EXTERNAL attribute, all subsequent references to SIN are to a user-supplied function named SIN, not to the intrinsic function of the same name.
You can include the name of a block data program unit in the EXTERNAL statement to force a search of the object module libraries for the block data program unit at link time. However, the name of the block data program unit must not be used in a type declaration statement.

If you want to describe a routine with greater detail, use the INTERFACE statement. This statement automatically declares a routine as EXTERNAL, and provides information on result types and argument types.

Example

The following example shows type declaration statements specifying the EXTERNAL attribute:

```plaintext
PROGRAM TEST
...
INTEGER, EXTERNAL :: BETA
LOGICAL, EXTERNAL :: COS
...
CALL SUB(BETA) ! External function BETA is an actual argument
```

You can use a name specified in an EXTERNAL statement as an actual argument to a subprogram, and the subprogram can then use the corresponding dummy argument in a function reference or a CALL statement; for example:

```plaintext
EXTERNAL FACET
CALL BAR(FACET)
SUBROUTINE BAR(F)
EXTERNAL F
CALL F(2)
```

Used as an argument, a complete function reference represents a value, not a subprogram; for example, FUNC(B) represents a value in the following statement:

```plaintext
CALL SUBR(A, FUNC(B), C)
```
The following shows another example:

```
EXTERNAL MyFunc, MySub

C MyFunc and MySub are arguments to Calc
   CALL Calc (MyFunc, MySub)

C Example of a user-defined function replacing an
C intrinsic
   EXTERNAL SIN
   x = SIN (a, 4.2, 37)
```

**FDATE**

*Portability Function and Subroutine:* Returns the current date and time as an ASCII string.

**Module**

```
USE IFPORT
```

**Syntax**

**Function Syntax**

```
result = FDATE()
```

**Subroutine Syntax:**

```
CALL FDATE ( [string] )
```

*string* (Output; optional) Character*(*)

It is returned as a 24-character string in the form:

```
Mon Jan 31 04:37:23 2001
```
Any value in string before the call is destroyed.

**Results**
The result of the function FDATE and the value of string returned by the subroutine FDATE(string) are identical. Newline and NULL are not included in the string.

When you use FDATE as a function, declare it as:

```fortran
CHARACTER*24 FDATE
```

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**
USE IFPORT
CHARACTER*24 today
!
CALL FDATE(today)
write (*,*), 'Today is ', today
!
write (*,*), 'Today is ', fdate()

**See Also**
- E to F
- DATE_AND_TIME

**FGETC**

*Portability Function:* Reads the next available character from a file specified by a Fortran unit number.

**Module**
USE IFPORT

**Syntax**
result = FGETC (lunit, char)
lunit  (Input) INTEGER(4). Unit number of a file. Must be currently connected to a file when the function is called.

char  (Output) CHARACTER*1. Next available character in the file. If lunit is connected to a console device, then no characters are returned until the Enter key is pressed.

Results

The result type is INTEGER(4). The result is zero if the read is successful, or -1 if an end-of-file is detected. A positive value is either a system error code or a Fortran I/O error code, such as:

EINVAL: The specified unit is invalid (either not already open, or an invalid unit number).

If you use WRITE, READ, or any other Fortran I/O statements with lunit, be sure to read Building Applications: Portability Routines: Input and Output Routines.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
CHARACTER inchar
INTEGER istatus
istatus = FGETC(5,inchar)
PRINT *, inchar
END

• E to F
• GETCHARQQ
• READ

FIND

Statement: Positions a direct access file at a particular record and sets the associated variable of the file to that record number. It is comparable
to a direct access READ statement with no I/O list, and it can open an existing file. No data transfer takes place.

Syntax

FIND ([UNIT=] io-unit, REC= r[, ERR= label] [, IOSTAT= i-var])
FIND (io-unit 'r [, ERR=label] [, IOSTAT=i-var])

io-unit Is a logical unit number. It must refer to a relative organization file (see Unit Specifier).

r Is the direct access record number. It cannot be less than one or greater than the number of records defined for the file (see Record Specifier).

label Is the label of the executable statement that receives control if an error occurs.

i-var Is a scalar integer variable that is defined as a positive integer if an error occurs, and as zero if no error occurs (see I/O Status Specifier).

Example

In the following example, the FIND statement positions logical unit 1 at the first record in the file. The file's associated variable is set to one:

FIND(1, REC=1)

In the following example, the FIND statement positions the file at the record identified by the content of INDX. The file's associated variable is set to the value of INDX:

FIND(4, REC=INDX)

See Also

- Forms for Direct-Access READ Statements
- I/O Control List
FINDFILEQQ

**Portability Function:** Searches for a specified file in the directories listed in the path contained in the environment variable.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{FINDFILEQQ}(\text{filename}, \text{varname}, \text{pathbuf})
\]

- **filename** (Input) Character*(*) Name of the file to be found.
- **varname** (Input) Character*(*) Name of an environment variable containing the path to be searched.
- **pathbuf** (Output) Character*(*) Buffer to receive the full path of the file found.

**Results**

The result type is INTEGER(4). The result is the length of the string containing the full path of the found file returned in pathbuf, or 0 if no file is found.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFPORT

CHARACTER(256) pathname

INTEGER(4) pathlen

pathlen = FINDFILEQQ("libfmt.lib", "LIB", pathname)

WRITE (*,*) pathlen

END

**See Also**

- E to F
- FULLPATHQQ
FIRSTPRIVATE

**Parallel Directive Clause:** Provides a superset of the functionality provided by the PRIVATE clause; objects are declared PRIVATE and they are initialized with certain values.

**Syntax**

```fortran
FIRSTPRIVATE (list)
```

*list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, private (local) copies of each variable in the different threads are initialized to the value the variable had before the parallel region started.

**See Also**

- E to F
- PRIVATE clause

*Building Applications:* Debugging Shared Variables

*Optimizing Applications:* PRIVATE, FIRSTPRIVATE, and LASTPRIVATE Clauses

*Optimizing Applications:* Worksharing Construct Directives

FIXEDFORMLINESIZE

**General Compiler Directive:** Sets the line length for fixed-form Fortran source code.

**Syntax**

```fortran
cDEC$ FIXEDFORMLINESIZE:(72 | 80 | 132)
```

*c* is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
You can set FIXEDFORMLINESIZE to 72 (the default), 80, or 132 characters. The FIXEDFORMLINESIZE setting remains in effect until the end of the file, or until it is reset.

The FIXEDFORMLINESIZE directive sets the source-code line length in include files, but not in USE modules, which are compiled separately. If an include file resets the line length, the change does not affect the host file.

This directive has no effect on free-form source code.

Example

cDEC$ NOFREEFORM

cDEC$ FIXEDFORMLINESIZE:132

        WRITE (*,*) 'Sentence that goes beyond the 72nd column without continuation.'

FLOAT

Elemental Intrinsic Function (Generic):
Converts an integer to REAL(4).

See Also

- E to F
- REAL

FLOODFILL, FLOODFILL_W (W*32, W*64)

Graphics Functions: Fill an area using the current color index and fill mask.

Module

USE IFQWIN
Syntax

\[ \text{result} = \text{FLOODFILL} \left( x, y, \text{bcolor} \right) \]
\[ \text{result} = \text{FLOODFILL}_W \left( wx, wy, \text{bcolor} \right) \]

\( x, y \) (Input) INTEGER(2). Viewport coordinates for fill starting point.

\( \text{bcolor} \) (Input) INTEGER(2). Color index of the boundary color.

\( wx, wy \) (Input) REAL(8). Window coordinates for fill starting point.

Results

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color \( \text{bcolor} \), or if the starting point lies outside the clipping region).

FLOODFILL begins filling at the viewport-coordinate point \((x, y)\). FLOODFILL_W begins filling at the window-coordinate point \((wx, wy)\). The fill color used by FLOODFILL and FLOODFILL_W is set by SETCOLOR. You can obtain the current fill color index by calling GETCOLOR. These functions allow access only to the colors in the palette (256 or less). To access all available colors on a VGA (262,144 colors) or a true color system, use the RGB functions FLOODFILLRGB and FLOODFILLRGB_W.

If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current graphics color index set by SETCOLOR. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color \( \text{bcolor} \).

NOTE. The FLOODFILL routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the FloodFill routine by including the IFWIN module, you need to specify the routine name as MSFWIN$FloodFill. For more information, see Building Applications: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example
USE IFQWIN

INTEGER(2) status, bcolor, red, blue
INTEGER(2) x1, y1, x2, y2, xinterior, yinterior
x1 = 80; y1 = 50
x2 = 240; y2 = 150
red = 4
blue = 1
status = SETCOLOR(red)
status = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
bcolor = GETCOLOR()
status = SETCOLOR (blue)
xinterior = 160; yinterior = 100
status = FLOODFILL (xinterior, yinterior, bcolor)
END

Building Applications: Setting Figure Properties
**FLOODFILLRGB, FLOODFILLRGB_W (W*32, W*64)**

**Graphics Functions:** Fill an area using the current Red-Green-Blue (RGB) color and fill mask.

**Module**
USE IFQWIN

**Syntax**

\[
\text{result} = \text{FLOODFILLRGB} (x, y, \text{color})
\]

\[
\text{result} = \text{FLOODFILLRGB}_W (wx, wy, \text{color})
\]

\[
x, y \\
\text{(Input) INTEGER(2). Viewport coordinates for fill starting point.}
\]

\[
\text{color} \\
\text{(Input) INTEGER(4). RGB value of the boundary color.}
\]

\[
wx, wy \\
\text{(Input) REAL(8). Window coordinates for fill starting point.}
\]

**Results**

The result type is INTEGER(4). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color \text{color}, or if the starting point lies outside the clipping region).

FLOODFILLRGB begins filling at the viewport-coordinate point \((x, y)\). FLOODFILLRGB_W begins filling at the window-coordinate point \((wx, wy)\). The fill color used by FLOODFILLRGB and FLOODFILLRGB_W is set by SETCOLORRGB. You can obtain the current fill color by calling GETCOLORRGB.

If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current color set by SETCOLORRGB. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color \text{color}.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as a QuickWin or Standard Graphics App.

USE IFQWIN

INTEGER(2) status
INTEGER(4) result, bcolor
INTEGER(2) x1, y1, x2, y2, xinterior, yinterior

x1 = 80; y1 = 50
x2 = 240; y2 = 150
result = SETCOLORRGB(Z'008080') ! red
status = RECTANGLE( $GBORDER, x1, y1, x2, y2 )

bcolor = GETCOLORRGB( )
result = SETCOLORRGB(Z'FF0000') ! blue
xinterior = 160; yinterior = 100
result = FLOODFILLRGB( xinterior, yinterior, bcolor )

END

- SETFILLMASK

Building Applications: Setting Figure Properties
**FLOOR**

*Elemental Intrinsic Function (Generic):*

*Returns the greatest integer less than or equal to its argument.*

**Syntax**

```
result = FLOOR (a[,kind])
```

- `a` (Input) Must be of type real.
- `kind` (Input; optional) Must be a scalar integer initialization expression.
  This argument is a Fortran 95 feature.

**Results**

The result type is integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is equal to the greatest integer less than or equal to `a`.

The setting of compiler options specifying integer size can affect this function.

**Example**

FLOOR (4.8) has the value 4.

FLOOR (-5.6) has the value -6.

The following shows another example:

```
I = FLOOR(3.1)  ! returns 3
I = FLOOR(-3.1) ! returns -4
```

**See Also**

- CEILING
FLUSH Directive

OpenMP* Fortran Compiler Directive: Identifies synchronization points at which the implementation must provide a consistent view of memory.

Syntax

c$OMP FLUSH ((list])

- `c` is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).
- `list` is the name of one or more variables to be flushed. Names must be separated by commas.

The FLUSH directive must appear at the precise point in the code at which the synchronization is required. To avoid flushing all variables, specify a `list`.

Thread-visible variables are written back to memory at the point at which this directive appears. Modifications to thread-visible variables are visible to all threads after this point. Subsequent reads of thread-visible variables fetch the latest copy of the data.

Thread-visible variables include the following data items:

- Globally visible variables (common blocks and modules)
- Local variables that do not have the SAVE attribute but have had their address taken and saved or have had their address passed to another subprogram
- Local variables that do not have the SAVE attribute that are declared shared in a parallel region within the subprogram
- Dummy arguments
- All pointer dereferences

The FLUSH directive is implied for the following directives (unless the NOWAIT keyword is used):

- BARRIER
- CRITICAL and END CRITICAL
- END DO
- END PARALLEL
- END SECTIONS
- END SINGLE
Example

The following example uses the FLUSH directive for point-to-point synchronization between pairs of threads:

```fortran
&$OMP PARALLEL DEFAULT(PRIVATE) SHARED(ISYNC)
  IAM = OMP_GET_THREAD_NUM()
  ISYNC(IAM) = 0
&$OMP BARRIER
  CALL WORK()
  C I AM DONE WITH MY WORK, SYNCHRONIZE WITH MY NEIGHBOR
  ISYNC(IAM) = 1
&$OMP FLUSH(ISYNC)
  C WAIT TILL NEIGHBOR IS DONE
  DO WHILE (ISYNC(NEIGH) .EQ. 0)
    &$OMP FLUSH(ISYNC)
    END DO
&$OMP END PARALLEL
```

See Also
- E to F
- OpenMP Fortran Compiler Directives
**FLUSH Statement**

*Statement:* Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement. It takes one of the following forms:

**Syntax**

```fortran
FLUSH([UNIT=io-unit [,ERR=label] [IOSTAT=i-var]])
```

- **io-unit** (Input) Is an external unit specifier.
- **label** (Input) Is the label of the branch target statement that receives control if an error occurs.
- **i-var** (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

The FLUSH statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

This statement has no effect on file position.

**FLUSH Subroutine**

*Portability Subroutine:* Flushes the contents of an external unit buffer into its associated file.

**Module**

```fortran
USE IFPORT
```

**Syntax**

```fortran
CALL FLUSH (lunit)
```

- **lunit** (Input) INTEGER(4). Number of the external unit to be flushed. Must be currently connected to a file when the subroutine is called. This routine is thread-safe, and locks the associated stream before I/O is performed.
NOTE. The flush is performed in a non-blocking mode. In this mode, the command may return before the physical write is completed. If you want to use a blocking mode of FLUSH use COMMITQQ.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• E to F
• COMMITQQ

FOCUSQQ (W*32, W*64)
QuickWin Function: Sets focus to the window with the specified unit number.

Module
USE IFQWIN

Syntax
result = FOCUSQQ (iunit)

iunit                   (Input) INTEGER(4). Unit number of the window to which the focus is set. Unit numbers 0, 5, and 6 refer to the default startup window.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

Units 0, 5, and 6 refer to the default window only if the program does not specifically open them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

Unlike SETACTIVEQQ, FOCUSQQ brings the specified unit to the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.
A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when an I/O statement is executed on that unit. For example:

```
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```

By default IOFOCUS=.TRUE., except for child windows opened with as unit *. If IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

**Compatibility**

QUICKWIN GRAPHICS LIB

**See Also**

- E to F
- SETACTIVEQQ
- INQFOCUSQQ

**Building Applications:** Using QuickWin Overview

**Building Applications:** Giving a Window Focus and Setting the Active Window

**FOR_DESCRIPTOR_ASSIGN (W*32, W*64)**

**Run-Time Subroutine:** Creates an array descriptor in memory.

**Module**

USE IFCORE

**Syntax**

```
CALL FOR_DESCRIPTOR_ASSIGN (dp, base, size, reserved, rank, dims_info) 
```

- **dp**
  (Input) A Fortran 95/90 pointer to an array; the array can be of any data type.

- **base**
  (Input) INTEGER(4) or INTEGER(8). The base address of the data being described by dp.

Note that a Fortran 95/90 pointer describes both the location and type of the data item.
size

(Input) INTEGER(4). The size of the data type; for example, 4 for INTEGER(4).

reserved

(Input) INTEGER(4). A logical bitwise OR combination of the following constants, which are defined in IFCORE.F90:

- FOR_DESCRIPTOR_ARRAY_DEFINED - Specifies whether the array pointed to has been allocated or associated. If the bit is set, the array has been allocated or associated.
- FOR_DESCRIPTOR_ARRAY_NODEALLOC - Specifies whether the array points to something that can be deallocated by a call to DEALLOCATE, or whether it points to something that cannot be deallocated. For example:

```fortran
integer, pointer :: p(:)
integer, target :: t
p => t  ! t cannot be deallocated
allocate(p(10)) ! t can be deallocated
```

If the bit is set, the array cannot be deallocated.

- FOR_DESCRIPTOR_ARRAY_CONTIGUOUS - Specifies whether the array pointed to is completely contiguous in memory or whether it is a slice that is not contiguous. If the bit is set, the array is contiguous.

rank

(Input) INTEGER(4). The rank of the array pointed to.

dims_info

(Input) An array of derived type FOR_DIMS_INFO; you must specify a rank for this array. The derived type FOR_DIMS_INFO is defined in IFCORE.F90 as follows:

```
TYPE FOR_DIMS_INFO
  INTEGER(4) LOWERBOUND !Lower bound for the dimension
  INTEGER(4) UPPERBOUND !Upper bound for the dimension
  INTEGER(4) STRIDE      !Stride for the dimension
END TYPE FOR_DIMS_INFO
```
The FOR_DESCRIPTOR_ASSIGN routine is similar to a Fortran 95/90 pointer assignment, but gives you more control over the assignment, allowing, for example, assignment to any location in memory.

You can also use this routine to create an array that can be used from both Fortran or C.

**Example**

```fortran
use IFCORE
common/c_array/ array
real(8) array(5,5)
external init_array
external c_print_array
real(8),pointer :: p_array(:,:)
type(FOR_DIMS_INFO) dims_info(2)
call init_array()

do i=1,5
   do j=1,5
      print *,i,j, array(i,j)
   end do
end do

dims_info(1)%LOWERBOUND = 11

dims_info(1)%UPPERBOUND = 15
dims_info(1)%STRIDE = 1

dims_info(2)%LOWERBOUND = -5
dims_info(2)%UPPERBOUND = -1
dims_info(2)%STRIDE = 1
```
The following shows the C program containing init_array and c_print_array:

```c
#include <stdio.h>
#if !defined(_WIN32) && !defined(_WIN64)
#define C_ARRAY c_array_
#define INIT_ARRAY init_array_
#define C_PRINT_ARRAY c_print_array_
#endif
double C_ARRAY[5][5];
void INIT_ARRAY(void);
void C_PRINT_ARRAY(void);
void INIT_ARRAY(void)
{
    int i,j;
    for(i=0;i<5;i++)
```
for(j=0;j<5;j++)
    C_ARRAY[i][j] = j + 10*i;
}
void C_PRINT_ARRAY(void)
{
    int i,j;

    for(i=0;i<5;i++)
    {
        for(j=0;j<5;j++)
            printf("%f ", C_ARRAY[i][j]);
        printf("\n");
    }
}

FOR_GET_FPE

Run-Time Function: Returns the current settings of floating-point exception flags. This routine can be called from a C or Fortran program.

Module
USE IFCORE

Syntax
result = FOR_GET_FPE()

Results
The result type is INTEGER(4). The return value represents the settings of the current floating-point exception flags. The meanings of the bits are defined in the IFPORT module file.
To set floating-point exception flags after program initialization, use FOR_SET_FPE.
Example

USE IFCORE

INTEGER*4 FPE_FLAGS

FPE_FLAGS = FOR_GET_FPE ( )

See Also

- E to F
- FOR_SET_FPE option for example

for_rtl_finish_

Run-Time Function: Cleans up the Fortran run-time environment; for example, flushing buffers and closing files. It also issues messages about floating-point exceptions, if any occur.

Syntax

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

result = for_rtl_finish_ ( )

Results

The result is an I/O status value. For information on these status values, see Building Applications: Using the IOSTAT Value and Fortran Exit Codes.

To initialize the Fortran run-time environment, use function for_rtl_init_.

Example

Consider the following C code:

int io_status;

int for_rtl_finish_ ( );

io_status = for_rtl_finish_ ( );

See Also

- E to F
- for_rtl_init_
for_rtl_init_

Run-Time Subroutine: Initializes the Fortran run-time environment. It establishes handlers and floating-point exception handling, so Fortran subroutines/procedures behave the same as when called from a Fortran main program.

Syntax

This routine should be called from a C main program; it is invoked by default from a Fortran main program.

CALL for_rtl_init_ (argcount, actarg)

argcount Is a command-line parameter describing the argument count.
actarg Is a command-line parameter describing the actual arguments.

To clean up the Fortran run-time environment, use function for_rtl_finish_.

Example

Consider the following C code:

```c
int argc;
char **argv;
void for_rtl_init_ (int *, char **);
for_rtl_init_ (&argc, argv);
```

See Also

- E to F
- for_rtl_finish_

FOR_SET_FPE

Run-Time Function: Sets the floating-point exception flags. This routine can be called from a C or Fortran program.

Module

USE IFCORE
**Syntax**

\[
\text{result} = \text{FOR\_SET\_FPE}\ (a)
\]

\(a\) Must be of type INTEGER(4). It contains bit flags controlling floating-point exception trapping, reporting, and result handling.

**Results**

The result type is INTEGER(4). The return value represents the previous settings of the floating-point exception flags. The meanings of the bits are defined in the IFCORE module file.

To get the current settings of the floating-point exception flags, use \text{FOR\_GET\_FPE}.

**Example**

```
USE IFCORE

INTEGER*4 OLD_FPE_FLAGS, NEW_FPE_FLAGS

OLD_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)
```
The following example program is compiled without any fpe options; however, it uses calls to for_set_fpe to enable the same flags as when compiling with the fpe:0 option. The new flags can be verified by compiling the program with the -fpe:0 option.

program samplefpe
use ifcore
implicit none
INTEGER(4) :: ORIGINAL_FPE_FLAGS, NEW_FPE_FLAGS
INTEGER(4) :: CURRENT_FPE_FLAGS, PREVIOUS_FPE_FLAGS
NEW_FPE_FLAGS = FPE_M_TRAP_UND + FPE_M_TRAP_OVF + FPE_M_TRAP_DIV0 &
+ FPE_M_TRAP_INV + FPE_M_ABRUPT_UND + FPE_M_ABRUPT_DMZ
ORIGINAL_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)
CURRENT_FPE_FLAGS = FOR_GET_FPE ()
print *,"The original FPE FLAGS were:"
CALL PRINT_FPE_FLAGS(ORIGINAL_FPE_FLAGS)
print *, ""
print *, "The new FPE FLAGS are:"

write(*,*) " FPE_ABRUPT_DMZ :", toggle, " (ftz related)"
end subroutine PRINT_FPE_FLAGS
The output from this program is as follows:

```bash
>ifort set_fpe_sample01.f90
>set_fpe_sample01.exe
```

The original FPE FLAGS were:

FPE FLAGS = 0X00000000 B'00000000000000000000000000000000

- FPE_TRAP_UND :OFF
- FPE_TRAP_OVF :OFF
- FPE_TRAP_DIV0 :OFF
- FPE_TRAP_INV :OFF
- FPE_ABRUPT_UND :OFF
- FPE_ABRUPT_OVF :OFF
- FPE_ABRUPT_DIV0 :OFF
- FPE_ABRUPT_INV :OFF
- FPE_ABRUPT_DMZ :OFF (ftz related)

The new FPE FLAGS are:

FPE FLAGS = 0X0011000F B'0000000000010001000000000001111

- FPE_TRAP_UND :ON
- FPE_TRAP_OVF :ON
- FPE_TRAP_DIV0 :ON
- FPE_TRAP_INV :ON
- FPE_ABRUPT_UND :ON
- FPE_ABRUPT_OVF :OFF
- FPE_ABRUPT_DIV0 :ON
- FPE_ABRUPT_INV :OFF
- FPE_ABRUPT_DMZ :ON (ftz related)
FOR_SET_REENTRANCY

Run-Time Function: Controls the type of reentrancy protection that the Fortran Run-Time Library (RTL) exhibits. This routine can be called from a C or Fortran program.

Module

USE IFCORE

Syntax

result = FOR_SET_REENTRANCY (mode)

mode Must be of type INTEGER(4) and contain one of the following options:

FOR_K_REENTRANCY_NONE Tells the Fortran RTL to perform simple locking around critical sections of RTL code. This type of reentrancy should be used when the Fortran RTL will not be reentered due to asynchronous system traps (ASTs) or threads within the application.

FOR_K_REENTRANCY_ASYNCH Tells the Fortran RTL to perform simple locking and disables ASTs around critical sections of RTL code. This type of reentrancy should be used when the application contains AST handlers that call the Fortran RTL.

FOR_K_REENTRANCY_THREADED Tells the Fortran RTL to perform thread locking. This type of reentrancy should be used in multithreaded applications.

FOR_K_REENTRANCY_INFO Tells the Fortran RTL to return the current reentrancy mode.

Results

The result type is INTEGER(4). The return value represents the previous setting of the Fortran Run-Time Library reentrancy mode, unless the argument is FOR_K_REENTRANCY_INFO, in which case the return value represents the current setting.
You must be using an RTL that supports the level of reentrancy you desire. For example, FOR_SET_REENTRANCY ignores a request for thread protection (FOR_K_REENTRANCY_THREADED) if you do not build your program with the thread-safe RTL.

Example

```fortran
PROGRAM SETREENT
USE IFCORE
INTEGER*4 MODE
CHARACTER*10 REENT_TXT(3) /'NONE ', 'ASYNC ', 'THREADED' /
PRINT*, 'Setting Reentrancy mode to ', REENT_TXT(MODE+1)
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_NONE)
PRINT*, 'Previous Reentrancy mode was ', REENT_TXT(MODE+1)
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_INFO)
PRINT*, 'Current Reentrancy mode is ', REENT_TXT(MODE+1)
END
```

FORALL

*Statement and Construct:* The FORALL statement and construct is an element-by-element generalization of the Fortran 95/90 masked array assignment (WHERE statement and construct). It allows more general array shapes to be assigned, especially in construct form.

**Syntax**

FORALL is a feature of Fortran 95.

**Statement:**

```
FORALL (triplet-spec[, triplet-spec] ...[, mask-expr]) assign-stmt
```

**Construct:**

```
[name:] FORALL (triplet-spec[, triplet-spec] ...[, mask-expr])
  forall-body-stmt
  [forall-body-stmt]...
END FORALL [name]
```
triplet-spec

Is a triplet specification with the following form:

\[ \text{subscript-name} = \text{subscript-1: subscript-2[: stride]} \]

The \text{subscript-name} is a scalar of type integer. It is valid only within the scope of the FORALL; its value is undefined on completion of the FORALL.

The \text{subscripts} and \text{stride} cannot contain a reference to any \text{subscript-name} in \text{triplet-spec}.

The \text{stride} cannot be zero. If it is omitted, the default value is 1.

Evaluation of an expression in a triplet specification must not affect the result of evaluating any other expression in another triplet specification.

mask-expr

Is a logical array expression (called the mask expression). If it is omitted, the value .TRUE. is assumed. The mask expression can reference the subscript name in \text{triplet-spec}.

triplet-spec

Is a triplet specification with the following form:

\[ \text{subscript-name} = \text{subscript-1: subscript-2[: stride]} \]

The \text{subscript-name} is a scalar of type integer. It is valid only within the scope of the FORALL; its value is undefined on completion of the FORALL.

The \text{subscripts} and \text{stride} cannot contain a reference to any \text{subscript-name} in \text{triplet-spec}.

The \text{stride} cannot be zero. If it is omitted, the default value is 1.

Evaluation of an expression in a triplet specification must not affect the result of evaluating any other expression in another triplet specification.

\section*{Description}

If a construct name is specified in the FORALL statement, the same name must appear in the corresponding END FORALL statement.

A FORALL statement is executed by first evaluating all bounds and stride expressions in the triplet specifications, giving a set of values for each subscript name. The FORALL assignment statement is executed for all combinations of subscript name values for which the mask expression is true.
The FORALL assignment statement is executed as if all expressions (on both sides of the assignment) are completely evaluated before any part of the left side is changed. Valid values are assigned to corresponding elements of the array being assigned to. No element of an array can be assigned a value more than once.

A FORALL construct is executed as if it were multiple FORALL statements, with the same triplet specifications and mask expressions. Each statement in the FORALL body is executed completely before execution begins on the next FORALL body statement.

Any procedure referenced in the mask expression or FORALL assignment statement must be pure.

Pure functions can be used in the mask expression or called directly in a FORALL statement. Pure subroutines cannot be called directly in a FORALL statement, but can be called from other pure procedures.

**Example**

The following example, which is not expressible using array syntax, sets diagonal elements of an array to 1:

```fortran
REAL, DIMENSION(N, N) :: A

FORALL (I=1:N) A(I, I) = 1
```

Consider the following:

```fortran
FORALL(I = 1:N, J = 1:N, A(I, J) .NE. 0.0) B(I, J) = 1.0 / A(I, J)
```

This statement takes the reciprocal of each nonzero element of array A(1:N, 1:N) and assigns it to the corresponding element of array B. Elements of A that are zero do not have their reciprocal taken, and no assignments are made to corresponding elements of B.

Every array assignment statement and WHERE statement can be written as a FORALL statement, but some FORALL statements cannot be written using just array syntax. For example, the preceding FORALL statement is equivalent to the following:

```fortran
WHERE(A /= 0.0) B = 1.0 / A
```

However, the following FORALL example cannot be written using just array syntax:

```fortran
FORALL(I = 1:N, J = 1:N) H(I, J) = 1.0/REAL(I + J - 1)
```

This statement sets array element H(I, J) to the value 1.0/REAL(I + J - 1) for values of I and J between 1 and N.
Consider the following:

```fortran
TYPE MONARCH
    INTEGER, POINTER :: p
END TYPE MONARCH

TYPE(MONARCH), DIMENSION(8) :: pattern
INTEGER, DIMENSION(8), TARGET :: object
FOR ALL(J=1:8) pattern(J)%p => object(1+ieor(j-1,2))
```

This FORALL statement causes elements 1 through 8 of array pattern to point to elements 3, 4, 1, 2, 7, 8, 5, and 6, respectively, of object. IOR can be referenced here because it is pure.

The following example shows a FORALL construct:

```fortran
FORALL(I = 3:N + 1, J = 3:N + 1)
  c(I, J) = c(I, J + 2) + c(I, J - 2) + c(I + 2, J) + c(I - 2, J)
  d(I, J) = c(I, J)
END FORALL
```

The assignment to array D uses the values of C computed in the first statement in the construct, not the values before the construct began execution.

**See Also**
- E to F
- WHERE

**FORMAT**

**Statement:** Specifies the form of data being transferred and the data conversion (editing) required to achieve that form.

**Syntax**

```fortran
FORMAT (format-list)
```

*format-list* is a list of one or more of the following edit descriptors, separated by commas or slashes (/):

---

2685
Control edit descriptors: T, TL, TR, X, S, SP, SS, BN, BZ, P, :, /, $, \, and Q.

String edit descriptors: H, 'c', and "c", where c is a character constant.

A comma can be omitted in the following cases:

- Between a P edit descriptor and an immediately following F, E, EN, ES, D, or G edit descriptor
- Before a slash (/) edit descriptor when the optional repeat specification is not present
- After a slash (/) edit descriptor
- Before or after a colon (:) edit descriptor

Edit descriptors can be nested and a repeat specification can precede data edit descriptors, the slash edit descriptor, or a parenthesized list of edit descriptors.

**Description**

A FORMAT statement must be labeled.

Named constants are not permitted in format specifications.

If the associated I/O statement contains an I/O list, the format specification must contain at least one data edit descriptor or the control edit descriptor Q.

Blank characters can precede the initial left parenthesis, and additional blanks can appear anywhere within the format specification. These blanks have no meaning unless they are within a character string edit descriptor.

When a formatted input statement is executed, the setting of the BLANK specifier (for the relevant logical unit) determines the interpretation of blanks within the specification. If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks. (For more information on BLANK defaults, see the OPEN statement.

For formatted input, use the comma as an external field separator. The comma terminates the input of fields (for noncharacter data types) that are shorter than the number of characters expected. It can also designate null (zero-length) fields.
The first character of a record transmitted to a line printer or terminal is typically used for carriage control; it is not printed. The first character of such a record should be a blank, 0, 1, $,+, or ASCII NUL. Any other character is treated as a blank.

A format specification cannot specify more output characters than the external record can contain. For example, a line printer record cannot contain more than 133 characters, including the carriage control character.

Whenever an edit descriptor requires an integer constant, you can specify an integer expression in a FORMAT statement. The integer expression must be enclosed by angle brackets (< and >). The following examples are valid format specifications:

```fortran
WRITE(6,20) INT1
20 FORMAT(I<MAX(20,5)>)
WRITE(6,FMT=30) INT2, INT3
30 FORMAT(I<J+K>, I<2*M>)
```

The integer expression can be any valid Fortran expression, including function calls and references to dummy arguments, with the following restrictions:

- Expressions cannot be used with the H edit descriptor.
- Expressions cannot contain graphical relational operators (such as > and <).

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement.

The following tables summarize the different kinds of edit descriptors:

**Table 797: Data Edit Descriptors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Form 1</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A[w]</td>
<td>Transfers character or Hollerith values.</td>

<td>Transfers real values with E exponents.</td>
</tr>
</tbody>
</table>
Transfers real values with engineering notation.

Transfers real values with scientific notation.

Transfers real values with no exponent.

Transfers values of all intrinsic types.

Transfers decimal integer values.

Transfers logical values: on input, transfers characters; on output, transfers T or F.

Transfers octal values.

Transfers hexadecimal values.

\( w \) is the field width.

\( m \) is the minimum number of digits that must be in the field (including zeros).

\( d \) is the number of digits to the right of the decimal point.

\( E \) is the exponent field.

\( e \) is the number of digits in the exponent.

**FP_CLASS**

*Elemental Intrinsic Function (Generic):*

*Returns the class of an IEEE real (S_floating, T_floating, or X_floating) argument. This function cannot be passed as an actual argument.*

**Syntax**

```fortran
result = FP_CLASS (x)
```

`x` (Input) Must be of type real.

**Results**

The result type is INTEGER(4). The return value is one of the following:

<table>
<thead>
<tr>
<th>Class of Argument</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signaling NaN</td>
<td>FOR_K_FP_SNAN</td>
</tr>
<tr>
<td>Quiet NaN</td>
<td>FOR_K_FP_QNAN</td>

</tr>
<tr>
<td>Class of Argument</td>
<td>Return Value</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>Negative Zero</td>
<td>FOR_K_FP_NEG_ZERO</td>
</tr>
</tbody>
</table>

The preceding return values are defined in file `for_fpclass.for`.

**Example**

FP_CLASS (4.0_8) has the value 4 (FOR_K_FP_POS_NORM).

**FPUTC**

*Portability Function:* Writes a character to the file specified by a Fortran external unit, bypassing normal Fortran input/output.

**Module**

USE IFPORT

**Syntax**

```
result = FPUTC (lunit, char)
```

- `lunit` (Input) INTEGER(4). Unit number of a file.
- `char` (Output) Character(*). Variable whose value is to be written to the file corresponding to `lunit`.

**Results**

The result type is INTEGER(4). The result is zero if the write was successful; otherwise, an error code, such as:

- EINVAL - The specified unit is invalid (either not already open, or an invalid unit number)

If you use WRITE, READ, or any other Fortran I/O statements with `lunit`, be sure to read *Building Applications: Input and Output With Portability Routines*.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

use IFPORT
integer*4 lunit, i4
character*26 string
character*1 char1
lunit = 1
open (lunit,file = 'fputc.dat')
do i = 1,26
   char1 = char(123-i)
i4 = fputc(1,char1) !make valid writes
   if (i4.ne.0) iflag = 1
endo
 rewind (1)
read (1,'(a)') string
print *, string

Building Applications: Files, Devices, and Input/Output Hardware

FRACTION

Elemental Intrinsic Function (Generic):
Returns the fractional part of the model representation of the argument value.

Syntax

result = FRACTION (x)

x                (Input) Must be of type real.
Results
The result type is the same as x. The result has the value \( x \times b^e \). Parameters \( b \) and \( e \) are defined in Model for Real Data. If \( x \) has the value zero, the result has the value zero.

Example
If 3.0 is a REAL(4) value, FRACTION (3.0) has the value 0.75.

The following shows another example:

```fortran
REAL result
result = FRACTION(3.0) ! returns 0.75
result = FRACTION(1024.0) ! returns 0.5
```

FREE

**Intrinsic Subroutine (Specific):** Frees a block of memory that is currently allocated. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL FREE (addr)
```

*addr* (Input) Must be of type INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. This value is the starting address of the memory block to be freed, previously allocated by MALLOC.

If the freed address was not previously allocated by MALLOC, or if an address is freed more than once, results are unpredictable.
Example

 INTEGER(4) SIZE
 REAL(4) STORAGE(*)
 POINTER (ADDR, STORAGE) ! ADDR will point to STORAGE
 SIZE = 1024 ! Size in bytes
 ADDR = MALLOC(SIZE) ! Allocate the memory
 CALL FREE(ADDR) ! Free it

FREEFORM and NOFREEFORM

General Compiler Directives: FREEFORM specifies that source code is in free-form format. NOFREEFORM specifies that source code is in fixed-form format.

Syntax

 cDEC$ FREEFORM
 cDEC$ NOFREEFORM
 C Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

When the FREEFORM or NOFREEFORM directives are used, they remain in effect for the remainder of the file, or until the opposite directive is used. When in effect, they apply to include files, but do not affect USE modules, which are compiled separately.

• free compiler option

Building Applications: Compiler Directives Related to Options
**FSEEK**

*Portability Function:* Repositions a file specified by a Fortran external unit.

**Module**

USE IFPORT

**Syntax**

```fortran
result = FSEEK (lunit, offset, from)
```

*lunit* *(Input)* INTEGER(4). External unit number of a file.

*offset* *(Input)* INTEGER(4) or INTEGER(8). Offset in bytes, relative to *from*, that is to be the new location of the file marker.

*from* *(Input)* INTEGER(4). A position in the file. It must be one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Variable</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>SEEK_SET</td>
<td>Positions the file relative to the beginning of the file.</td>
</tr>
<tr>
<td>1</td>
<td>SEEK_CUR</td>
<td>Positions the file relative to the current position.</td>
</tr>
<tr>
<td>2</td>
<td>SEEK_END</td>
<td>Positions the file relative to the end of the file.</td>
</tr>
</tbody>
</table>

**Results**

The result type is INTEGER(4). The result is zero if the repositioning was successful; otherwise, an error code, such as:

EINVAL: The specified unit is invalid (either not already open, or an invalid unit number), or the *from* parameter is invalid.

The file specified in *lunit* must be open.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
integer(4) istat, offset, ipos
character ichar
OPEN (unit=1, file='datfile.dat')
offset = 5
ipos = 0
istat=fseek(1, offset, ipos)
if (.NOT. stat) then
  istat=fgetc(1, ichar)
  print *, 'data is ', ichar
end if

FSTAT

Portability Function: Returns detailed information about a file specified by a external unit number.

Module
USE IFPORT

Syntax
result = FSTAT (lunit, statb)

lunit (Input) INTEGER(4). External unit number of the file to examine.
statb (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of statb contain the following values:
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>statb(1)</td>
<td>Device the file resides on</td>
<td>W<em>32, W</em>64: Always 0</td>

</tbody>
</table>

\(^1\)Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, returns an error code equal to EINVAL (\(lunit\) is not a valid unit number, or is not open).

The access mode (the third element of \(statb\)) is a bitmap consisting of an IOR of the following constants:

<table>
<thead>
<tr>
<th>Symbolic name</th>

FTELL, FTELLI8

Portability Functions: Return the current position of a file.

Module
USE IFPORT

Syntax

result = FTELL (lunit)
result = FTELLI8 (lunit)

lunit (Input) INTEGER(4). External unit number of a file.

Results

The result type is INTEGER(4) for FTELL; INTEGER(8) for FTELLI8. The result is the offset, in bytes, from the beginning of the file. A negative value indicates an error, which is the negation of the IERRNO error code. The following is an example of an error code:

EINVAL: lunit is not a valid unit number, or is not open.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

FULLPATHQQ

Portability Function: Returns the full path for a specified file or directory.

Module
USE IFPORT

Syntax
result = FULLPATHQQ (name, pathbuf)

name (Input) Character*(*). Item for which you want the full path. Can be the name of a file in the current directory, a relative directory or file name, or a network uniform naming convention (UNC) path.

pathbuf (Output) Character*(*). Buffer to receive full path of the item specified in name.

Results
The result type is INTEGER(4). The result is the length of the full path in bytes, or 0 if the function fails. This function does not verify that the resulting path and file name are valid nor that they exist.

The length of the full path depends upon how deeply the directories are nested on the drive you are using. If the full path is longer than the character buffer provided to return it (pathbuf), FULLPATHQQ returns only that portion of the path that fits into the buffer.

Check the length of the path before using the string returned in pathbuf. If the longest full path you are likely to encounter does not fit into the buffer you are using, allocate a larger character buffer. You can allocate the largest possible path buffer with the following statements:

USE IFPORT
CHARACTER($MAXPATH) pathbuf

$MAXPATH is a symbolic constant defined in IFPORT.F90 as 260.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT
USE IFCORE
CHARACTER($MAXPATH) buf
CHARACTER(3) drive
CHARACTER(256) dir
CHARACTER(256) name
CHARACTER(256) ext
CHARACTER(256) file
INTEGER(4) len
DO WHILE (.TRUE.)
  WRITE (*,*)
  WRITE (*,'(A, ")') ' Enter filename (Hit &
      RETURN to exit): '
  len = GETSTRQQ(file)
  IF (len .EQ. 0) EXIT
  len = FULLPATHQQ(file, buf)
  IF (len .GT. 0) THEN
    WRITE (*,*) buf(:len)
  ELSE
    WRITE (*,*) 'Can''t get full path'
    EXIT
  END IF
!
  ! Split path
  WRITE (*,*)
  len = SPLITPATHQQ(buf, drive, dir, name, ext)
  IF (len .NE. 0) THEN

WRITE (*, 900) ' Drive: ', drive
WRITE (*, 900) ' Directory: ', dir(1:len)
WRITE (*, 900) ' Name: ', name
WRITE (*, 900) ' Extension: ', ext
ELSE
WRITE (*, *) 'Can''t split path'
END IF
END DO
900 FORMAT (A, A)
END

See Also
- E to F
- SPLITPATHQQ

FUNCTION

Statement: The initial statement of a function subprogram. A function subprogram is invoked in an expression and returns a single value (a function result) that is used to evaluate the expression.

Syntax

[prefix [prefix]] FUNCTION name [([d-arg-list])] [suffix]
    [specification-part]
    [execution-part]
[CONTAINS
    internal-subprogram-part]
END [FUNCTION [name]]

prefix

(Optional) Is any of the following:
- A data type specifier
- RECURSIVE
Permits direct recursion to occur. If a function is directly recursive and array valued, RESULT must also be specified.

- **PURE**
  
  Asserts that the procedure has no side effects.

- **ELEMENTAL**
  
  Acts on one array element at a time. This is a restricted form of pure procedure.

At most one of each of the above can be specified. You cannot specify ELEMENTAL and RECURSIVE together. You cannot specify ELEMENTAL if lang-binding is specified in suffix.

**name**

Is the name of the function. If RESULT is specified, the function name must not appear in any specification statement in the scoping unit of the function subprogram.

The function name can be followed by the length of the data type. The length is specified by an asterisk (*) followed by any unsigned, nonzero integer that is a valid length for the function's type. For example, REAL FUNCTION LGFUNC*8 (Y, Z) specifies the function result as REAL(8) (or REAL*8). This optional length specification is not permitted if the length has already been specified following the keyword CHARACTER.

**d-arg-list**

(Optional) Is a list of one or more dummy arguments.

If there are no dummy arguments and no RESULT variable, the parentheses can be omitted. For example, the following is valid:

    FUNCTION F

**suffix**

(Optional) Takes one of the following forms:

    [RESULT (r-name)] lang-binding
    lang-binding [RESULT (r-name)]

**r-name**

(Optional) Is the name of the function result.

This name must not be the same as the function name.

**lang-binding**

Takes the following form:

    BIND (C [, NAME=ext-name])
Is a character scalar initialization expression that can be used to construct the external name.

**ext-name**

**specification-part** is one or more specification statements, except for the following:

- INTENT (or its equivalent attribute)
- OPTIONAL (or its equivalent attribute)
- PUBLIC and PRIVATE (or their equivalent attributes)

An automatic object must not appear in a specification statement. If a SAVE statement is specified, it has no effect.

**execution-part** is one or more executable constructs or statements, except for ENTRY or RETURN statements.

**internal-subprogram-part** is one or more internal subprograms (defining internal procedures). The **internal-subprogram-part** is preceded by a CONTAINS statement.

**Description**

The type and kind parameters (if any) of the function's result can be defined in the FUNCTION statement or in a type declaration statement within the function subprogram, but not both. If no type is specified, the type is determined by implicit typing rules in effect for the function subprogram.

Execution begins with the first executable construct or statement following the FUNCTION statement. Control returns to the calling program unit once the END statement (or a RETURN statement) is executed.

If you specify CHARACTER*(*), the function assumes the length declared for it in the program unit that invokes it. This type of character function can have different lengths when it is invoked by different program units; it is an obsolescent feature in Fortran 95.

If the length is specified as an integer constant, the value must agree with the length of the function specified in the program unit that invokes the function. If no length is specified, a length of 1 is assumed.

If the function is array-valued or a pointer, the declarations within the function must state these attributes for the function result name. The specification of the function result attributes, dummy argument attributes, and the information in the procedure heading collectively define the interface of the function.
The value of the result variable is returned by the function when it completes execution. Certain rules apply depending on whether the result is a pointer, as follows:

- If the result is a pointer, its allocation status must be determined before the function completes execution. The function must associate a target with the pointer, or cause the pointer to be explicitly disassociated from a target.
  The shape of the value returned by the function is determined by the shape of the result variable when the function completes execution.

- If the result is not a pointer, its value must be defined before the function completes execution. If the result is an array, all the elements must be defined. If the result is a derived-type structure, all the components must be defined.

A function subprogram cannot contain a BLOCK DATA statement, a PROGRAM statement, or a MODULE statement. A function can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

**Example**

The following example uses the Newton-Raphson iteration method \( (F(X) = \cosh(X) + \cos(X) - A = 0) \) to get the root of the function:

```fortran
FUNCTION ROOT(A)
  X = 1.0
  DO
    EX = EXP(X)
    EMINX = 1./EX
    ROOT = X - ((EX+EMINX)*.5+COS(X)-A)/((EX-EMINX)*.5-SIN(X))
    IF (ABS((X-ROOT)/ROOT) .LT. 1E-6) RETURN
    X = ROOT
  END DO
END
```

In the preceding example, the following formula is calculated repeatedly until the difference between \( X_i \) and \( X_{i+1} \) is less than 1.0E-6:
The following example shows an assumed-length character function:

```fortran
CHARACTER*(*) FUNCTION REDO(CARG)
    CHARACTER*1 CARG
    DO I=1,LEN(REDO)
        REDO(I:I) = CARG
    END DO
    RETURN
END FUNCTION
```

This function returns the value of its argument, repeated to fill the length of the function.

Within any given program unit, all references to an assumed-length character function must have the same length. In the following example, the REDO function has a length of 1000:

```fortran
CHARACTER*1000 REDO, MANYAS, MANYZS
MANYAS = REDO('A')
MANYZS = REDO('Z')
```

Another program unit within the executable program can specify a different length. For example, the following REDO function has a length of 2:

```fortran
CHARACTER HOLD*6, REDO*2
HOLD = REDO('A') // REDO('B') // REDO('C')
```

The following example shows a dynamic array-valued function:

```fortran
FUNCTION SUB (N)
    REAL, DIMENSION(N) :: SUB

    ...
END FUNCTION
```
The following shows another example:

```
INTEGER Divby2
10  PRINT *, 'Enter a number'
    READ *, i
    Print *, Divby2(i)
    GOTO 10
END
```

```
C
C This is the function definition
C
INTEGRAL FUNCTION Divby2 (num)
Divby2=num / 2
END FUNCTION
```
The following example shows an allocatable function with allocatable arguments:

```fortran
MODULE AP

CONTAINS

FUNCTION ADD_VEC(P1,P2)
  ! Function to add two allocatable arrays of possibly differing lengths.
  ! The arrays may be thought of as polynomials (coefficients)
  REAL, ALLOCATABLE :: ADD_VEC(:), P1(:), P2(:)
  ! This function returns an allocatable array whose length is set to
  ! the length of the larger input array.
  ALLOCATE(ADD_VEC(MAX(SIZE(P1), SIZE(P2))))
  M = MIN(SIZE(P1), SIZE(P2))
  ! Add up to the shorter input array size
  ADD_VEC(:M) = P1(:M) + P2(:M)
  ! Use the larger input array elements afterwards (from P1 or P2)
  IF(SIZE(P1) > M) THEN
    ADD_VEC(M+1:) = P1(M+1:)
  ELSE IF(SIZE(P2) > M) THEN
    ADD_VEC(M+1:) = P2(M+1:)
  ENDIF
END FUNCTION

END MODULE

PROGRAM TEST
 USE AP

REAL, ALLOCATABLE :: P(:), Q(:), R(:), S(:)
ALLOCATE(P(3))
ALLOCATE(Q(2))
ALLOCATE(R(3))
ALLOCATE(S(3))
 ! Notice that P and Q differ in length
```
P = (/4, 2, 1/) ! P = X**2 + 2X + 4
Q = (/1, 1/) ! Q = X - 1
PRINT *, 'Result should be: 3.000000 3.000000 1.000000'
PRINT *, 'Coefficients are: ', ADD_VEC(P, Q) ! X**2 + 3X + 3
P = (/1, 1, 1/) ! P = X**2 + X + 1
R = (/2, 2, 2/) ! R = 2X**2 + 2X + 2
S = (/3, 3, 3/) ! S = 3X**2 + 3X + 3
PRINT *, 'Result should be: 6.000000 6.000000 6.000000'
PRINT *, 'Coefficients are: ', ADD_VEC(ADD_VEC(P, R), S)
END

G

GERROR

Run-Time Subroutine: Returns a message for the last error detected by a Fortran run-time routine.

Module
USE IFCORE
Syntax

CALL GERROR (string)

string  (Output) Character*(*). Message corresponding to the last detected error.

The last detected error does not necessarily correspond to the most recent function call. The compiler resets string only when another error occurs.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFCORE

character*40 errtext
character char1
integer*4 iflag, i4
. . .!Open unit 1 here
i4=fgetc(1,char1)
if (i4) then
  iflag = 1
  Call GERROR (errtext)
  print *, errtext
end if

GETACTIVEQQ (W*32, W*64)

QuickWin Function: Returns the unit number of the currently active child window.

Module
USE IFQWIN

Syntax
result = GETACTIVEQQ( )

Results
The result type is INTEGER(4). The result is the unit number of the currently active window. If no child window is active, it returns the parameter QWIN$NOACTIVEWINDOW (defined in IFQWIN.F90).

Compatibility
QUICKWIN GRAPHICS LIB

See Also
• G
• SETACTIVEQQ
• GETHWNDQQ

Building Applications: Using QuickWin Overview
Building Applications: Giving a Window Focus and Setting the Active Window

GETARCINFO (W*32, W*64)

Graphics Function: Determines the endpoints (in viewport coordinates) of the most recently drawn arc or pie.

Module
USE IFQWIN

Syntax
result = GETARCINFO (pstart, pend, ppaint)
\texttt{pstart} \hspace{1cm} \text{(Output) Derived type \texttt{xycoord}. Viewport coordinates of the starting point of the arc.}

\texttt{pend} \hspace{1cm} \text{(Output) Derived type \texttt{xycoord}. Viewport coordinates of the end point of the arc.}

\texttt{ppaint} \hspace{1cm} \text{(Output) Derived type \texttt{xycoord}. Viewport coordinates of the point at which the fill begins.}

\textbf{Results}

The result type is \texttt{INTEGER(2)}. The result is nonzero if successful. The result is zero if neither the \texttt{ARC} nor the \texttt{PIE} function has been successfully called since the last time \texttt{CLEARSCREEN} or \texttt{SETWINDOWCONFIG} was successfully called, or since a new viewport was selected.

\texttt{GETARCINFO} updates the \texttt{pstart} and \texttt{pend} \texttt{xycoord} derived types to contain the endpoints (in viewport coordinates) of the arc drawn by the most recent call to the \texttt{ARC} or \texttt{PIE} functions. The \texttt{xycoord} derived type, defined in \texttt{IFQWIN.F90}, is:

\begin{verbatim}
 TYPE xycoord  
  INTEGER(2) xcoord  
  INTEGER(2) ycoord  
END TYPE xycoord
\end{verbatim}

The returned value in \texttt{ppaint} specifies a point from which a pie can be filled. You can use this to fill a pie in a color different from the border color. After a call to \texttt{GETARCINFO}, change colors using \texttt{SETCOLORRGB}. Use the new color, along with the coordinates in \texttt{ppaint}, as arguments for the \texttt{FLOODFILLRGB} function.

\textbf{Compatibility}

\begin{verbatim}
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
\end{verbatim}
Example

USE IFQWIN

INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4

TYPE (xycoord) xystart, xyend, xyfillpt

x1 = 80; y1 = 50
x2 = 240; y2 = 150
x3 = 120; y3 = 80
x4 = 90; y4 = 180

status = ARC(x1, y1, x2, y2, x3, y3, x4, y4)
status = GETARCINFO(xystart, xyend, xyfillpt)
END

• SETCOLORRGB

GETARG

_Intrinsic Subroutine:_ Returns the specified command-line argument (where the command itself is argument number zero). This subroutine cannot be passed as an actual argument.

Syntax

CALL GETARG (n, buffer[, , status])

n

(Input) Must be a scalar of type integer. This value is the position of the command-line argument to retrieve. The command itself is argument number 0.
buffer  (Output) Must be a scalar of type default character. Its value is the returned command-line argument.

status  (Output; optional) Must be a scalar of type integer. If specified, its value is the returned completion status.
If there were no errors, status returns the number of characters in the retrieved command-line argument before truncation or blank-padding. (That is, status is the original number of characters in the command-line argument.) Errors return a value of -1. Errors include specifying an argument position less than 0 or greater than the value returned by IARGC.

GETARG returns the n-th command-line argument. If n is zero, the name of the executing program file is returned.

GETARG returns command-line arguments as they were entered. There is no case conversion.
If the command-line argument is shorter than buffer, GETARG pads buffer on the right with blanks. If the argument is longer than buffer, GETARG truncates the argument on the right. If there is an error, GETARG fills buffer with blanks.

Example
Assume a command-line invocation of PROG1 -g -c -a, and that buffer is at least five characters long. The following calls to GETARG return the corresponding arguments in buffer and status:

<table>
<thead>
<tr>
<th>Statement</th>
<th>String returned in buffer</th>
<th>Length returned in status</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL GETARG (0, buffer, status)</td>
<td>PROG1</td>
<td>5</td>
</tr>
<tr>
<td>CALL GETARG (1, buffer)</td>
<td>-g</td>
<td>undefined</td>
</tr>
<tr>
<td>CALL GETARG (2, buffer, status)</td>
<td>-c</td>
<td>2</td>
</tr>
<tr>
<td>CALL GETARG (3, buffer)</td>
<td>-a</td>
<td>undefined</td>
</tr>
<tr>
<td>CALL GETARG (4, buffer, status)</td>
<td>all blanks</td>
<td>-1</td>
</tr>
</tbody>
</table>

GETBKCOLOR (W*32, W*64)

*Graphics Function:* Returns the current background color index for both text and graphics output.

**Module**

USE IFQWIN

**Syntax**

result = GETBKCOLOR()

**Results**

The result type is INTEGER(4). The result is the current background color index.

GETBKCOLOR returns the current background color index for both text and graphics, as set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB. Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background index is 0, which is associated with black unless the user remaps the palette with REMAPPALETTERGB.
NOTE. The GETBKCOLOR routine described here is a QuickWin routine. If you are trying
to use the Microsoft* Platform SDK version of the GetBkColor routine by including the
IFWIN module, you need to specify the routine name as MSFWIN$GetBkColor. For more
information, see Building Applications: Special Naming Convention for Certain QuickWin
and Win32 Graphics Routines.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example
USE IFQWIN

INTEGER(4) bcindex

bcindex = GETBKCOLOR()

See Also
• G
• GETBKCOLORRGB
• SETBKCOLOR
• GETCOLOR
• GETTEXTCOLOR
• REMAPALLPALETTERGB, REMAPPALETTERGB

Building Applications: Setting Figure Properties
Building Applications: Using Text Colors

GETBKCOLORRGB (W*32, W*64)

Graphics Function: Returns the current
background Red-Green-Blue (RGB) color value for
both text and graphics.

Module
USE IFQWIN

Syntax

result = GETBKCOLORRGB( )
Results

The result type is INTEGER(4). The result is the RGB value of the current background color for both text and graphics.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETBKCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24 23</th>
<th>16 15</th>
<th>8 7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B</td>
<td>G G G G G G</td>
<td>R R R R R R</td>
<td></td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex FF) the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFFFF' full-intensity for all three, resulting in bright white.

GETBKCOLORRGB returns the RGB color value of the current background for both text and graphics, set with SETBKCOLORRGB. The RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT) is set with SETTEXTCOLORRGB and returned with GETTEXTCOLORRGB. The RGB color value of graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and FLOODFILLRGB) is set with SETCOLORRGB and returned with GETCOLORRGB.

SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETBKCOLOR, SETCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
**Example**

! Build as a QuickWin or Standard Graphics App.

USE IFQWIN

INTEGER(4) back, fore, oldcolor
INTEGER(2) status, x1, y1, x2, y2

x1 = 80; y1 = 50
x2 = 240; y2 = 150

oldcolor = SETCOLORRGB(Z'FF') ! red
! reverse the screen
back = GETBKCOLORRGB()
fore = GETCOLORRGB()
oldcolor = SETBKCOLORRGB(fore)
oldcolor = SETCOLORRGB(back)

CALL CLEARSCREEN ($GCLEARSCREEN)

char
```

*(Output) Character*(*). First character typed at the keyboard after the call to GETC. If unit 5 is connected to a console device, then no characters are returned until the Enter key is pressed.

**Results**

The result type is INTEGER(4). The result is zero if successful, or -1 if an end-of-file was detected.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAHICS WINDOWS DLL LIB

**Example**

```fortran
use IFPORT
character ans, errtxt*40
print *, 'Enter a character: '
ISTAT = GETC (ans)
if (istat) then
call gerror(errtxt)
end if
```

**See Also**

- GETSTRQQ
GETCHARQQ

Run-Time Function: Returns the next keystroke.

Module
USE IF CORE

Syntax
result = GETCHARQQ()

Results
The result type is character with length 1. The result is the character representing the key that was pressed. The value can be any ASCII character.

If the key pressed is represented by a single ASCII character, GETCHARQQ returns the character.

If the key pressed is a function or direction key, a hex Z'00' or Z'E0' is returned. If you need to know which function or direction was pressed, call GETCHARQQ a second time to get the extended code for the key.

If there is no keystroke waiting in the keyboard buffer, GETCHARQQ waits until there is one, and then returns it. Compare this to the function PEEKCHARQQ, which returns .TRUE. if there is a character waiting in the keyboard buffer, and .FALSE. if not. You can use PEEKCHARQQ to determine if GETCHARQQ should be called. This can prevent a program from hanging while GETCHARQQ waits for a keystroke that isn't there. Note that PEEKCHARQQ is only supported in console applications.

If your application is a QuickWin or Standard Graphics application, you may want to put a call to PASSDIRKEYSQQ in your program. This will enable the program to get characters that would otherwise be trapped. These extra characters are described in PASSDIRKEYSQQ.

Note that the GETCHARQQ routine used in a console application is a different routine than the one used in a QuickWin or Standard Graphics application. The GETCHARQQ used with a console application does not trap characters that are used in QuickWin for a special purpose, such as scrolling. Console applications do not need, and cannot use PASSDIRKEYSQQ.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
Example

! Program to demonstrate GETCHARQQ

USE IFCORE

CHARACTER(1) key / 'A' /

PARAMETER (ESC = 27)
PARAMETER (NOREP = 0)

WRITE (*,*) ' Type a key: (or q to quit)'
! Read keys until ESC or q is pressed

DO WHILE (ICHAR(key) .NE. ESC)

  key = GETCHARQQ()

  ! Some extended keys have no ASCII representation
  IF (ICHAR(key) .EQ. NOREP) THEN
    key = GETCHARQQ()
    WRITE (*, 900) 'Not ASCII. Char = NA'
    WRITE (*,*)
  ELSE
    WRITE (*,900) 'ASCII. Char = '
    WRITE (*,901) key
  END IF

  IF (key .EQ. 'q' ) THEN
    EXIT
  END IF

END DO

GETCOLOR (W*32, W*64)

*Graphics Function:* Returns the current graphics color index.

**Module**

USE IFQWIN

**Syntax**

result = GETCOLOR()

**Results**

The result type is INTEGER(2). The result is the current color index, if successful; otherwise, -1.

GETCOLOR returns the current color index used for graphics over the background color as set with SETCOLOR. The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Program to demonstrate GETCOLOR

PROGRAM COLORS
USE IFQWIN
INTEGER(2) loop, loop1, status, color
LOGICAL(4) winstat
REAL rnd1, rnd2, xnum, ynum
type (windowconfig) wc
status = SETCOLOR(INT2(0))
! Color random pixels with 15 different colors
DO loop1 = 1, 15
  color = INT2(MOD(GETCOLOR() +1, 16))
  status = SETCOLOR (color) ! Set to next color
  DO loop = 1, 75
    ! Set color of random spot, normalized to be on screen
    CALL RANDOM(rnd1)
    CALL RANDOM(rnd2)
    winstat = GETWINDOWCONFIG(wc)
    xnum = wc%numxpixels
    ynum = wc%numypixels
    status = &
    SETPIXEL(INT2(rnd1*xnum+1),INT2(rnd2*ynum))
    status = &
    SETPIXEL(INT2(rnd1*xnum),INT2(rnd2*ynum+1))
    status = &
    SETPIXEL(INT2(rnd1*xnum-1),INT2(rnd2*ynum))
    status = &
    SETPIXEL(INT2(rnd1*xnum),INT2(rnd2*ynum-1))

Building Applications: Setting Figure Properties

GETCOLORRGB (W*32, W*64)

Graphics Function: Returns the current graphics color Red-Green-Blue (RGB) value (used by graphics functions such as ARC, ELLIPSE, and FLOODFILLRGB).

Module
USE IFQWIN

Syntax
result = GETCOLORRGB( )

Results
The result type is INTEGER(4). The result is the RGB value of the current graphics color.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
</table>
| RGB | 0 0 0 0 0 0 0 0 | B  B  B  B  B  B  G  G  G  G  G  G  G  G  G  G  R  R  R  R  R  R  R  R  R
Larger numbers correspond to stronger color intensity with binary 1111111 (hex FF) the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETCOLORRGB returns the RGB color value of graphics over the background color (used by graphics functions such as ARC, ELLIPSE, and FLOODFILLRGB), set with SETCOLORRGB. GETBKCOLORRGB returns the RGB color value of the current background for both text and graphics, set with SETBKCOLORRGB. GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB.

SETCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
Example

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
INTEGER(4) fore, oldcolor
numfonts = INITIALIZEFONTS ( )
oldcolor = SETCOLORRGB(Z'FF') ! set graphics
! color to red
fore = GETCOLORRGB()
oldcolor = SETBKCOLORRGB(fore) ! set background
! to graphics color
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB (Z'FF0000') ! set graphics
! color to blue
CALL OUTGTEXT("hello, world")
END

GET_COMMAND

**Intrinsic Subroutine:** Returns the entire command that was used to invoke the program.

**Syntax**

CALL GET_COMMAND ([command, length, status])

- **command** (Output; optional) Must be a scalar of type default character. If specified, its value is the entire command that was used to invoke the program. If the command cannot be determined, its value is all blanks.

- **length** (Output; optional) Must be a scalar of type integer. If specified, its value is the significant length of the command that was used to invoke the program. This length includes trailing blanks, but it does not include any truncation or padding used in the command. If the command length cannot be determined, its value is zero.

- **status** (Output; optional) Must be a scalar of type integer. If specified, its value is -1 if the command argument is present and has a length less than the significant length of the command. If the command cannot be retrieved, its value is positive; otherwise, it is assigned the value zero.

**Example**

See the example in **COMMAND_ARGUMENT_COUNT**.

GET_COMMAND_ARGUMENT

Intrinsic Subroutine: Returns a command line argument of the command that invoked the program. This subroutine cannot be passed as an actual argument.

Syntax

CALL GET_COMMAND_ARGUMENT (number[, value, length, status])

number  (Input) Must be a scalar of type integer. It must be non-negative and less than or equal to the value returned by the COMMAND_ARGUMENT_COUNT function. Its value is the position of the command-line argument to retrieve. The command itself is argument number zero.

value    (Output; optional) Must be a scalar of type default character. If specified, its value is the returned command-line argument or all blanks if the value is unknown.

length   (Output; optional) Must be a scalar of type integer. If specified, its value is the length of the returned command-line argument or zero if the length of the argument is unknown. This length includes significant trailing blanks. It does not include any truncation or padding that occurs when the argument is assigned to the value argument.

status   (Output; optional) Must be a scalar of type integer. If specified, its value is the returned completion status. It is assigned the value -1 if the value argument is present and has a length less than the significant length of the command argument specified by number. It is assigned a processor-dependent positive value if the argument retrieval fails. Otherwise, it is assigned the value zero.

GET_COMMAND_ARGUMENT returns command-line arguments as they were entered. There is no case conversion.

Example

See the example in COMMAND_ARGUMENT_COUNT.

<td>Allow inexact precision</td>
</tr>
</tbody>
</table>

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. Exceptions can be disabled by setting the control bits to 1 with SETCONTROLFPQQ. If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues.
You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ. If errors on floating-point exceptions are enabled (by clearing the control bits to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause run-time errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings. For a full discussion of the floating-point control word, exceptions, and error handling, see Building Applications: The Floating-Point Environment Overview.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
INTEGER(2) control
CALL GETCONTROLFPQQ (control)
! if not rounding down
IF (IAND(control, FPCW$DOWN) .NE. FPCW$DOWN) THEN
  control = IAND(control, NOT(FPCW$MCW_RC)) ! clear all
    ! rounding
  control = IOR(control, FPCW$DOWN) ! set to
    ! round down
CALL SETCONTROLFPQQ(control)
END IF
END

**Building Applications**: Exception Parameters

**Building Applications**: Floating-Point Control Word Overview

**GETCURRENTPOSITION, GETCURRENTPOSITION_W (W*32, W*64)**

*Graphics Subroutines*: Return the coordinates of the current graphics position.

**Module**

USE IFQWIN

**Syntax**

CALL GETCURRENTPOSITION (t)

CALL GETCURRENTPOSITION_W (wt)

**t**

(Output) Derived type *xycoord*. Viewport coordinates of current graphics position. The derived type *xycoord* is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
  INTEGER(2) xcoord  ! x-coordinate
  INTEGER(2) ycoord  ! y-coordinate
END TYPE xycoord
```

**wt**

(Output) Derived type *wxycoord*. Window coordinates of current graphics position. The derived type *wxycoord* is defined in IFQWIN.F90 as follows:

```
TYPE wxycoord
  REAL(8) wx       ! x-coordinate
  REAL(8) wy       ! y-coordinate
END TYPE wxycoord
```

LINETO, MOVETO, and OUTGTEXT all change the current graphics position. It is in the center of the screen when a window is created.
Graphics output starts at the current graphics position returned by `GETCURRENTPOSITION` or `GETCURRENTPOSITION_W`. This position is not related to normal text output (from `OUTTEXT` or `WRITE`, for example), which begins at the current text position (see `SETTEXTPOSITION`). It does, however, affect graphics text output from `OUTGTEXT`.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

```fortran
! Program to demonstrate GETCURRENTPOSITION
USE IFQWIN
TYPE (xycoord) position
INTEGER(2) result
result = LINETO(INT2(300), INT2(200))
CALL GETCURRENTPOSITION( position )
IF (position%xcoord .GT. 50) THEN
   CALL MOVETO(INT2(50), position%ycoord, position)
   WRITE(*,*) "Text unaffected by graphics position"
END IF
result = LINETO(INT2(300), INT2(200))
END
```

GETDRIVEDIRQQ

Portability Function: Returns the path of the current working directory on a specified drive.

Module
USE IFPORT

Syntax
result = GETDRIVEDIRQQ (drivedir)
drivedir (Input; output) Character*(*) . On input, drive whose current working directory path is to be returned. On output, string containing the current directory on that drive in the form d:\dir.

Results
The result type is INTEGER(4). The result is the length (in bytes) of the full path of the directory on the specified drive. Zero is returned if the path is longer than the size of the character buffer drivedir.

You specify the drive from which to return the current working directory by putting the drive letter into drivedir before calling GETDRIVEDIRQQ. To make sure you get information about the current drive, put the symbolic constant FILE$CURDRIVE (defined in IFPORT.F90) into drivedir.

Because drives are identified by a single alphabetic character, GETDRIVEDIRQQ examines only the first letter of drivedir. For instance, if drivedir contains the path c:\fps90\bin, GETDRIVEDIRQQ (drivedir) returns the current working directory on drive C and disregards the rest of the path. The drive letter can be uppercase or lowercase.

The length of the path returned depends on how deeply the directories are nested on the drive specified in drivedir. If the full path is longer than the length of drivedir, GETDRIVEDIRQQ returns only the portion of the path that fits into drivedir. If you are likely to encounter a long path, allocate a buffer of size $MAXPATH ($MAXPATH = 260).

On Linux* and Mac OS* X systems, the function gets a path only when symbolic constant FILE$CURDRIVE has been applied to drivedir.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
Example

! Program to demonstrate GETDRIVEDIRQQ
USE IFPORT
CHARACTER($MAXPATH) dir
INTEGER(4) length
! Get current directory
dir = FILE$CURDRIVE
length = GETDRIVEDIRQQ(dir)
IF (length .GT. 0) THEN
  WRITE (*,*),'Current directory is: '
  WRITE (*,*), dir
ELSE
  WRITE (*,*),'Failed to get current directory'
ENDIF
END

- CHANGEDIRQQ
- GETDRIVESIZEQQ
- GETDRIVESQQ
- GETLASTERRORQQ
- SPLITPATHQQ

GETDRIVESIZEQQ

Portability Function: Returns the total size of the specified drive and space available on it.

Module
USE IFPORT
Syntax

\[ \text{result} = \text{GETDRIVESIZEQQ} \left( \text{drive}, \text{total}, \text{avail} \right) \]

- **drive** (Input) Character*(*). String containing the letter of the drive to get information about.
- **total** (Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8). Total number of bytes on the drive.
- **avail** (Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8). Number of bytes of available space on the drive.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The data types and dimension (if any) specified for the \textit{total} and \textit{avail} arguments must be the same. Specifying an array of two INTEGER(4) elements, or an INTEGER(8) argument, allows drive sizes larger than 2147483647 to be returned.

If an array of two INTEGER(4) elements is specified, the least-significant 32 bits are returned in the first element, the most-significant 32 bits in the second element. If an INTEGER(4) scalar is specified, the least-significant 32 bits are returned.

Because drives are identified by a single alphabetic character, GETDRIVESIZEQQ examines only the first letter of \textit{drive}. The drive letter can be uppercase or lowercase. You can use the constant FILE$\text{CURDRIVE}$ (defined in IFPORT.F90) to get the size of the current drive.

If GETDRIVESIZEQQ fails, use GETLASTERRORQQ to determine the reason.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

! Program to demonstrate GETDRIVESQQ and GETDRIVESIZEQQ
USE IFPORT
CHARACTER(26) drives
CHARACTER(1) adrive
LOGICAL(4) status
INTEGER(4) total, avail
INTEGER(2) i
! Get the list of drives
drives = GETDRIVESQQ()
WRITE (*,'(A,A)') ' Drives available: ', drives
!
! Cycle through them for free space and write to console
DO i = 1, 26
  adrive = drives(i:i)
  status = .FALSE.
  WRITE (*,'(A,A,A,\)') ' Drive ', CHAR(i + 64), ':'
  IF (adrive .NE. ' ') THEN
    status = GETDRIVESIZEQQ(adrive, total, avail)
  END IF
  IF (status) THEN
    WRITE (*,*) avail, ' of ', total, ' bytes free.'
  ELSE
    WRITE (*,*) 'Not available'
  END IF
END DO
END

GETDRIVESQQ

*Portability Function:* Reports which drives are available to the system.

Module
USE IFPORT

Syntax
result = GETDRIVESQQ( )

Results
The result type is character with length 26. It is the positional character string containing the letters of the drives available in the system.

The returned string contains letters for drives that are available, and blanks for drives that are not available. For example, on a system with A, C, and D drives, the string 'A CD' is returned.

On Linux* and Mac OS* X systems, the function returns a string filled with spaces.

Compatibility

GETENV

*Portability Subroutine:* Returns the value of an environment variable.

**Module**

USE IFPORT

**Syntax**

CALL GETENV (ename, evalue)

*ename* (Input) Character*(*). Environment variable to search for.

*evalue* (Output) Character*(*). Value found for *ename*. Blank if *ename* is not found.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

use IFPORT

character*40 libname

CALL GETENV ("LIB", libname)

TYPE *, "The LIB variable points to ", libname

**See Also**

• G

• GETENV

GET_ENVIRONMENT_VARIABLE

*Intrinsic Subroutine:* Gets the value of an environment variable.

**Syntax**

CALL GET_ENVIRONMENT_VARIABLE (name [, value, length, status, trim_name])
<table>
<thead>
<tr>
<th><strong>name</strong></th>
<th>(Input) Must be a scalar of type default character. It is the name of the environment variable.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>value</strong></td>
<td>(Output; optional) Must be a scalar of type default character. If specified, it is assigned the value of the environment variable specified by <em>name</em>. If the environment variable does not exist, <em>value</em> is assigned all blanks.</td>
</tr>
<tr>
<td><strong>length</strong></td>
<td>Must be a scalar of type integer. If specified, its value is the length of the environment variable, if it exists; otherwise, <em>length</em> is set to 0.</td>
</tr>
<tr>
<td><strong>status</strong></td>
<td>(Output; optional) Must be a scalar of type integer. If specified, it is assigned a value of 0 if the environment variable exists and either has no value or its value is successfully assigned to <em>value</em>. It is assigned a value of 1 if the environment variable does not exist. For other error conditions, it is assigned a processor-dependent value greater than 2.</td>
</tr>
<tr>
<td><strong>trim_name</strong></td>
<td>(Input; optional) Must be a scalar of type logical. If the value is FALSE, then trailing blanks in <em>name</em> are considered significant. Otherwise, they are not considered part of the environment variable’s name.</td>
</tr>
</tbody>
</table>
Example

The following program asks for the name of an environment variable. If the environment variable exists in the program's environment, it prints out its value:

```fortran
program print_env_var
character name*20, val*40
integer len, status
write (*) 'enter the name of the environment variable'
read (*) name
call get_environment_variable (name, val, len, status, .true.)
if (status .ge. 2) then
   write (*) 'get_environment_variable failed: status = ', status
   stop
end if
if (status .eq. 1) then
   write (*) 'env var does not exist'
   stop
end if
if (status .eq. -1) then
   write (*) 'env var length = ', len, ' truncated to 40'
   len = 40
end if
if (len .eq. 0) then
   write (*) 'env var exists but has no value'
   stop
end if
write (*) 'env var value = ', val (1:len)
end
```

When the above program is invoked, the following line is displayed:

```
enter the name of the environment variable
```
The following shows an example of what could be displayed if you enter "HOME".

- On a Linux* OS or Mac OS* X system:
  
  ```
  env var value = /home/our_space/usr4
  ```

- On a Windows* OS system:
  
  ```
  env var value = C:/
  ```

The following shows an example of what could be displayed if you enter "PATH".

- On a Linux OS or Mac OS X system:
  
  ```
  env var length = 307 truncated to 40
  env var value = /site/our_space/usr4/progs/build_area
  ```

- On a Windows OS system:
  
  ```
  env var length = 829 truncated to 40
  env var value = C:\OUR_SPACE\BUILD_AREA\build_objects\GETENVQQ
  ```

**GETENVQQ**

*Portability Function: Returns the value of an environment variable.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = GETENVQQ (varname, value)
```

- `varname` (Input) Character*(*)
- `value` (Output) Character*(*)

**Results**

The result type is INTEGER(4). The result is the length of the string returned in `value`. Zero is returned if the given variable is not defined.
GETENVQQ searches the list of environment variables for an entry corresponding to *varname*. Environment variables define the environment in which a process executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

Note that some environment variables may exist only on a per-process basis and may not be present at the command-line level.

GETENVQQ uses the C runtime routine getenv and SETENVQQ uses the C runtime routine _putenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.

In a program that uses the main function, _environ is initialized at program startup to settings taken from the operating system's environment.

Changes made outside the program by the console SET command, for example, SET MY_VAR=ABCDE, will be reflected by GETENVQQ.

GETENVQQ and SETENVQQ will not work properly with the Windows* APIs GetEnvironmentVariable and SetEnvironmentVariable.

**Compatibility**

GETEXCEPTIONPTRSQQ (i32, i64em; W*32, W*64)

Run-Time Function: Returns a pointer to C run-time exception information pointers appropriate for use in signal handlers established with SIGNALQQ or direct calls to the C rtl signal( ) routine.

Module

USE IFCORE

Syntax

result = GETEXCEPTIONPTRSQQ( )

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The return value is the address of a data structure whose members are pointers to exception information captured by the C runtime at the time of an exception. This result value can then be used as the eptr argument to routine TRACEBACKQQ to generate a stack trace from a user-defined handler or to inspect the exception context record directly.

Calling GETEXCEPTIONPTRSQQ is only valid within a user-defined handler that was established with SIGNALQQ or a direct call to the C rtl signal( ) function.

For a full description of exceptions and error handling, see Building Applications: The Floating-Point Environment Overview.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
Example

PROGRAM SIGTEST
USE IFCORE
...
R3 = 0.0E0
STS = SIGNALQQ(MY_HANDLER)
! Cause a divide by zero exception
R1 = 3.0E0/R3
...
END

INTEGER(4) FUNCTION MY_HANDLER(SIGNUM,EXCNUM)
USE IFCORE
...
EPTRS = GETEXCEPTIONPTRSQQ()
...
CALL TRACEBACKQQ("Application SIGFPE error!",USER_EXIT_CODE=-1,EPTR=EPTRS)
...

Building Applications: Using SIGNALQQ
GETEXITQQ (W*32, W*64)

QuickWin Function: Returns the setting for a QuickWin application’s exit behavior.

Module
USE IFQWIN

Syntax
result = GETEXITQQ()

Results
The result type is INTEGER(4). The result is exit mode with one of the following constants (defined in IFQWIN.F90):

- QWIN$EXITPROMPT - Displays a message box that reads "Program exited with exit status \( n \). Exit Window?", where \( n \) is the exit status from the program.
  
  If you choose Yes, the application closes the window and terminates. If you choose No, the dialog box disappears and you can manipulate the window as usual. You must then close the window manually.

- QWIN$EXITNOPERSIST - Terminates the application without displaying a message box.
- QWIN$EXITPERSIST - Leaves the application open without displaying a message box.

The default for both QuickWin and Console Graphics applications is QWIN$EXITPROMPT.

Compatibility
STANDARD GRAPHICS QUICKWIN.EXE LIB
Example

! Program to demonstrate GETEXITQQ
USE IFQWIN

Building Applications: Using QuickWin Overview

GETFILEINFOQQ

Portability Function: Returns information about the specified file. File names can contain wildcards (* and ?).

Module
USE IFPORT

Syntax
result = GETFILEINFOQQ (files, buffer, handle)

files (Input) Character*(*) Name or pattern of files you are searching for. Can include a full path and wildcards (* and ?).
**buffer**

(Output) Derived type `FILE$INFO` or derived type `FILE$INFOI8`. Information about a file that matches the search criteria in `files`. The derived type `FILE$INFO` is defined in `IFPORT.F90` as follows:

```fortran
TYPE FILE$INFO
  INTEGER(4) CREATION ! CREATION TIME (-1 on FAT)
  INTEGER(4) LASTWRITE ! LAST WRITE TO FILE
  INTEGER(4) LASTACCESS ! LAST ACCESS (-1 on FAT)
  INTEGER(4) LENGTH ! LENGTH OF FILE
  INTEGER(4) PERMIT ! FILE ACCESS MODE
  CHARACTER(255) NAME ! FILE NAME
END TYPE FILE$INFO
```

The derived type `FILE$INFOI8` is defined in `IFPORT.F90` as follows:

```fortran
TYPE FILE$INFO
  INTEGER(4) CREATION ! CREATION TIME (-1 on FAT)
  INTEGER(4) LASTWRITE ! LAST WRITE TO FILE
  INTEGER(4) LASTACCESS ! LAST ACCESS (-1 on FAT)
  INTEGER(8) LENGTH ! LENGTH OF FILE
  INTEGER(4) PERMIT ! FILE ACCESS MODE
  CHARACTER(255) NAME ! FILE NAME
END TYPE FILE$INFO
```

**handle**

(Input; output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. Control mechanism. One of the following constants, defined in `IFPORT.F90`:

- **FILE$FIRST** - First matching file found.
- **FILE$LAST** - Previous file was the last valid file.
- **FILE$ERROR** - No matching file found.
Results

The result type is INTEGER(4). The result is the nonblank length of the file name if a match was found, or 0 if no matching files were found.

To get information about one or more files, set the handle to FILE$FIRST and call GETFILEINFOQQ. This will return information about the first file which matches the name and return a handle. If the program wants more files, it should call GETFILEINFOQQ with the handle. GETFILEINFOQQ must be called with the handle until GETFILEINFOQQ sets handle to FILE$LAST, or system resources may be lost.

The derived-type element variables FILE$INFO%CREATION, FILE$INFO%LASTWRITE, and FILE$INFO%LASTACCESS contain packed date and time information that indicates when the file was created, last written to, and last accessed, respectively. To break the time and date into component parts, call UNPACKTIMEQQ. FILE$INFO%LENGTH contains the length of the file in bytes. FILE$INFO%PERMIT contains a set of bit flags describing access information about the file as follows:

<table>
<thead>
<tr>
<th>Bit flag</th>
<th>Access information for the file</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE$ARCHIVE</td>
<td>Marked as having been copied to a backup device.</td>
</tr>
<tr>
<td>FILE$DIR</td>
<td>A subdirectory of the current directory. Each MS-DOS directory contains two special files, &quot;.&quot; and &quot;..&quot;. These are directory aliases created by MS-DOS for use in relative directory notation. The first refers to the current directory, and the second refers to the current directory's parent directory.</td>
</tr>
<tr>
<td>FILE$HIDDEN</td>
<td>Hidden. It does not appear in the directory list you request from the command line, the Microsoft visual development environment browser, or File Manager.</td>
</tr>
<tr>
<td>FILE$READONLY</td>
<td>Write-protected. You can read the file, but you cannot make changes to it.</td>
</tr>
<tr>
<td>FILE$SYSTEM</td>
<td>Used by the operating system.</td>
</tr>
<tr>
<td>Bit flag</td>
<td>Access information for the file</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------------------------------------------</td>
</tr>
<tr>
<td>FILE$VOLUME</td>
<td>A logical volume, or partition, on a physical disk drive. This type of file appears only in the root directory of a physical device.</td>
</tr>
</tbody>
</table>

You can use the constant FILE$NORMAL to check that all bit flags are set to 0. If the derived-type element variable FILE$INFO%PERMIT is equal to FILE$NORMAL, the file has no special attributes. The variable FILE$INFO%NAME contains the short name of the file, not the full path of the file.

If an error occurs, call GETLASTERRORQQ to retrieve the error message, such as:

- ERR$NOENT: The file or path specified was not found.
- ERR$NOMEM: Not enough memory is available to execute the command, the available memory has been corrupted, or an invalid block exists, indicating that the process making the call was not allocated properly.

GETFILLMASK (W*32, W*64)

Graphics Subroutine: Returns the current pattern used to fill shapes.

Module

USE IFQWIN
Syntax

CALL GETFILLMASK (mask)

mask (Output) INTEGER(1). One-dimensional array of length 8.

There are 8 bytes in mask, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of mask becomes the top 8 bits of the pattern, and the eighth element (byte) of mask becomes the bottom 8 bits.

During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of 0 are unchanged. The current graphics color is set with SETCOLORRGB or SETCOLOR. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with SETFILLMASK), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (FLOODFILLRGB, PIE, ELLIPSE, POLYGON, and RECTANGLE).

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as QuickWin or Standard Graphics

Building Applications: Setting Figure Properties
GETFONTINFO (W*32, W*64)

Graphics Function: Returns the current font characteristics.

Module

 USE IFQWIN

Syntax

result = GETFONTINFO (font)

font (Output) Derived type FONTINFO. Set of characteristics of the current font. The FONTINFO derived type is defined in IFQWIN.F90 as follows:

TYPE FONTINFO

  INTEGER(4) type ! 1 = truetype, 0 = bit map
  INTEGER(4) ascent ! Pixel distance from top to baseline
  INTEGER(4) pixwidth ! Character width in pixels, 0=proportional
  INTEGER(4) pixheight ! Character height in pixels
  INTEGER(4) avgwidth ! Average character width in pixels
  CHARACTER(81) filename ! File name including path
  CHARACTER(32) facename ! Font name
  LOGICAL(1) italic ! .TRUE. if current font formatted italic
  LOGICAL(1) emphasized ! .TRUE. if current font formatted bold
  LOGICAL(1) underline ! .TRUE. if current font formatted underlined
END TYPE FONTINFO
**Results**

The result type is INTEGER(2). The result is zero if successful; otherwise, -1.

You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETFONTINFO.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

! Build as QuickWin or Standard Graphics

USE IFQWIN

TYPE (FONTINFO) info

INTEGER(2) numfonts, return, line_spacing

numfonts = INITIALIZEFONTS()

return = GETFONTINFO(info)

line_spacing = info%pixheight + 2

END

*Building Applications*: Using Fonts from the Graphics Library Overview

*Building Applications*: Setting the Font and Displaying Text
GETGID

**Portability Function:** Returns the group ID of the user of a process.

**Module**

USE IFPORT

**Syntax**

\[ \text{result} = \text{GETGID}() \]

**Results**

The result type is INTEGER(4). The result corresponds to the primary group of the user under whose identity the program is running. The result is returned as follows:

- On Windows* systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.
  
  Note that on Windows systems, domain accounts and local accounts can overlap.

- On Linux* and Mac OS* X systems, this function returns the group identity for the current process.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFPORT

ISTAT = GETGID( )

GETGTEXTEXTENT (W*32, W*64)

**Graphics Function:** Returns the width in pixels that would be required to print a given string of text (including any trailing blanks) with OUTGTEXT using the current font.

**Module**

USE IFQWIN
Syntax

result = GETGTEXTEXTENT (text)

text       (Input) Character*(*) Text to be analyzed.

Results

The result type is INTEGER(2). The result is the width of text in pixels if successful; otherwise, -1 (for example, if fonts have not been initialized with INITIALIZEFONTS).

This function is useful for determining the size of text that uses proportionally spaced fonts. You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETGTEXTEXTENT.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) status, pwidth
CHARACTER(80) text
status= INITIALIZEFONTS( )
status= SETFONT('t''Arial''h22w10')
pwidth= GETGTEXTEXTENT('How many pixels wide is this?')
WRITE(*,*),pwidth
END

See Also

• G
• GETFONTINFO
• OUTGTEXT
• SETFONT
• INITIALIZEFONTS
• GETGTEXTROTATION

Building Applications: Selecting Display Options
GETGTEXTROTATION (W*32, W*64)

Graphics Function: Returns the current orientation of the font text output by OUTGTEXT.

Module
USE IFQWIN

Syntax
result = GETGTEXTROTATION()

Results
The result type is INTEGER(4). It is the current orientation of the font text output in tenths of degrees. Horizontal is 0°, and angles increase counterclockwise so that 900 tenths of degrees (90°) is straight up, 1800 tenths of degrees (180°) is upside-down and left, 2700 tenths of degrees (270°) is straight down, and so forth.

The orientation for text output with OUTGTEXT is set with SETGTEXTROTATION.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER ang
REAL rang
ang = GETGTEXTROTATION()
rang = FLOAT(ang)/10.0
WRITE(*,*) "Text tilt in degrees is: ", rang
END

GETHWNDQQ (W*32, W*64)

**QuickWin Function:** Converts a window unit number into a Windows* handle.

**Module**

USE IFQWIN

**Syntax**

```plaintext
result = GETHWNDQQ (unit)
```

*Input* INTEGER(4). The window unit number. If `unit` is set to QWIN$FRAMEWINDOW (defined in IFQWIN.F90), the handle of the frame window is returned.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. The result is a true Windows handle to the window. If `unit` is not open, it returns -1.

**Compatibility**

QUICKWIN GRAPHICS LIB

- `GETUNITQQ`
- `SETACTIVEQQ`

*Building Applications:* Using QuickWin Overview

*Building Applications:* Giving a Window Focus and Setting the Active Window

*Building Applications:* Using Windows API Routines with QuickWin
**GETIMAGE, GETIMAGE_W (W^32, W^64)**

*Graphics Subroutines:* Store the screen image defined by a specified bounding rectangle.

**Module**

```
USE IFQWIN
```

**Syntax**

```
CALL GETIMAGE (x1,y1,x2,y2,image)
CALL GETIMAGE_W (wx1,wy1,wx2,wy2,image)
```

- `x1, y1` (Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.
- `x2, y2` (Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.
- `wx1, wy1` (Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.
- `wx2, wy2` (Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.
- `image` (Output) INTEGER(1). Array of single-byte integers. Stored image buffer.

**GETIMAGE** defines the bounding rectangle in viewport-coordinate points \((x_1, y_1)\) and \((x_2, y_2)\). **GETIMAGE_W** defines the bounding rectangle in window-coordinate points \((wx_1, wy_1)\) and \((wx_2, wy_2)\).

The buffer used to store the image must be large enough to hold it. You can determine the image size by calling IMAGESIZE at run time, or by using the formula described under IMAGESIZE. After you have determined the image size, you can dimension the buffer accordingly.

**Compatibility**

```
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
```
**Example**

! Build as QuickWin or Standard Graphics

USE IFQWIN

INTEGER(1), ALLOCATABLE:: buffer(:)

INTEGER(2) status, x, y, error

INTEGER(4) isize

x = 50
y = 30

status = ELLIPSE (G$FILLINTERIOR, INT2(x-15), &
INT2(y-15), INT2(x+15), INT2(y+15))

isize = IMAGESIZE (INT2(x-16), INT2(y-16), &
INT2(x+16), INT2(y+16))

ALLOCATE(buffer(isize), STAT = error)

IF (error .NE. 0) THEN
    STOP 'ERROR: Insufficient memory'
END IF

CALL GETIMAGE (INT2(x-16), INT2(y-16), &
INT2(x+16), INT2(y+16), buffer)

END

**See Also**

- G
- IMAGESIZE
- PUTIMAGE

*Building Applications*: Transferring Images in Memory

**GETLASTERROR**

*Portability Function*: Returns the last error set.

**Module**

USE IFPORT
Syntax

result = GETLASTERROR( )

Results

The result type is INTEGER(4). The result is the integer corresponding to the last run-time error value that was set.

For example, if you use an ERR= specifier in an I/O statement, your program will not abort if an error occurs. GETLASTERROR provides a way to determine what the error condition was, with a better degree of certainty than just examining(errno). Your application can then take appropriate action based upon the error number.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB

GETLASTERRORQQ

Portability Function: Returns the last error set by a run-time procedure.

Module

USE IFPORT

Syntax

result = GETLASTERRORQQ( )

Results

The result type is INTEGER(4). The result is the most recent error code generated by a run-time procedure.

Library functions that return a logical or integer value sometimes also provide an error code that identifies the cause of errors. GETLASTERRORQQ retrieves the most recent error message. The error constants are defined in IFPORT.F90. The following table shows some library routines and the errors each routine produces:

<table>

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB

**GETLINESTYLE (W*32, W*64)**

*Graphics Function:* Returns the current graphics line style.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = GETLINESTYLE()  
```
The result type is INTEGER(2). The result is the current line style.

GETLINESTYLE retrieves the mask (line style) used for line drawing. The mask is a 16-bit number, where each bit represents a pixel in the line being drawn.

If a bit is 1, the corresponding pixel is colored according to the current graphics color and logical write mode; if a bit is 0, the corresponding pixel is left unchanged. The mask is repeated for the entire length of the line. The default mask is Z'FFFF' (a solid line). A dashed line can be represented by Z'FF00' (long dashes) or Z'F0F0' (short dashes).

The line style is set with SETLINESTYLE. The current graphics color is set with SETCOLORRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.

The line style retrieved by GETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE or PIE.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

```
! Build as Graphics

USE IFQWIN

INTEGER(2) lstyle
lstyle = GETLINESTYLE()
WRITE (*, 100) lstyle, lstyle

100 FORMAT (1X, 'Line mask in Hex ', Z4, ' and binary ', B16)

END
```

Building Applications: Setting Figure Properties

GETLOG

Portability Subroutine: Returns the user's login name.

Module
USE IFPORT

Syntax
CALL GETLOG (name)

name (Output) Character*(*) User's login name.

The login name must be less than or equal to 64 characters. If the login name is longer than 64 characters, it is truncated. The actual parameter corresponding to name should be long enough to hold the login name. If the supplied actual parameter is too short to hold the login name, the login name is truncated.

If the login name is shorter than the actual parameter corresponding to name, the login name is padded with blanks at the end, until it reaches the length of the actual parameter.

If the login name cannot be determined, all blanks are returned.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
use IFPORT
character*20 username
CALL GETLOG (username)
print *, "You logged in as ", username
GETPHYSCOORD (W*32, W*64)

Graphics Subroutine: Translates viewport coordinates to physical coordinates.

Module
USE IFQWIN

Syntax
CALL GETPHYSCOORD (x, y, t)

x, y  (Input) INTEGER(2). Viewport coordinates to be translated to physical coordinates.

 t:  (Output) Derived type xycoord. Physical coordinates of the input viewport position. The xycoord derived type is defined in IFQWIN.F90 as follows:

   TYPE xycoord
      INTEGER(2) xcoord ! x-coordinate
      INTEGER(2) ycoord ! y-coordinate
   END TYPE xycoord

Physical coordinates refer to the physical screen. Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area. For a more complete discussion of coordinate systems, see Building Applications: Understanding Coordinate Systems Overview.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Program to demonstrate GETPHYSCOORD, GETVIEWCOORD, 
! and GETWINDOWCOORD. Build as QuickWin or Standard 
! Graphics

USE IFQWIN

TYPE (xycoord) viewxy, physxy

TYPE (wxycoord) windxy

CALL SETVIEWPORT(INT2(80), INT2(50), &
    INT2(240), INT2(150))

! Get viewport equivalent of point (100, 90)
CALL GETVIEWCOORD (INT2(100), INT2(90), viewxy)

! Get physical equivalent of viewport coordinates
CALL GETPHYSCOORD (viewxy%xcoord, viewxy%ycoord, &
    physxy)

! Get physical equivalent of viewport coordinates
CALL GETWINDOWCOORD (viewxy%xcoord, viewxy%ycoord, &
    windxy)

! Write viewport coordinates
WRITE (*,*) viewxy%xcoord, viewxy%ycoord

! Write physical coordinates
WRITE (*,*) physxy%xcoord, physxy%ycoord

! Write window coordinates
WRITE (*,*) windxy%wx, windxy%wy

END

GETPID

*Portability Function:* Returns the process ID of the current process.

**Module**

USE IFPORT

**Syntax**

result = GETPID()

**Results**

The result type is INTEGER(4). The result is the process ID number of the current process.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFPORT

INTEGER(4) istat

istat = GETPID()

GETPIXEL, GETPIXEL_W (W*32, W*64)

*Graphics Functions:* Return the color index of the pixel at a specified location.

**Module**

USE IFQWIN

**Syntax**

result = GETPIXEL (x, y)

result = GETPIXEL_W (wx, wy)
(Input) INTEGER(2). Viewport coordinates for pixel position.

wx, wy  (Input) REAL(8). Window coordinates for pixel position.

Results
The result type is INTEGER(2). The result is the pixel color index if successful; otherwise, -1
(if the pixel lies outside the clipping region, for example).

Color routines without the RGB suffix, such as GETPIXEL, use color indexes, not true color
values, and limit you to colors in the palette, at most 256. To access all system colors, use
SETPIXELRGB to specify an explicit Red-Green-Blue value and retrieve the value with
GETPIXELRGB.

NOTE. The GETPIXEL routine described here is a QuickWin routine. If you are trying to
use the Microsoft* Platform SDK version of the GetPixel routine by including the IFWIN
module, you need to specify the routine name as MSFWIN$GetPixel. For more information,
see Building Applications: Special Naming Convention for Certain QuickWin and Win32
Graphics Routines.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

• GETPIXELS
• SETPIXEL

2778
GETPIXELRGB, GETPIXELRGB_W (W*32, W*64)

Graphics Functions: Return the Red-Green-Blue (RGB) color value of the pixel at a specified location.

Module
USE IFQWIN

Syntax
result = GETPIXELRGB (x, y)
result = GETPIXELRGB_W (wx, wy)

x, y  (Input) INTEGER(2). Viewport coordinates for pixel position.
wx, wy (Input) REAL(8). Window coordinates for pixel position.

Results
The result type is INTEGER(4). The result is the pixel's current RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETPIXELRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B B B</td>
<td>G G G G G G G G</td>
<td>R R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETPIXELRGB returns the true color value of the pixel, set with SETPIXELRGB, SETCOLORRGB, SETBKCOLORRGB, or SETTEXTCOLORRGB, depending on the pixel's position and the current configuration of the screen.

SETPIXELRGB (and the other RGB color selection functions SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB) sets color to a color value chosen from the entire available range. The non-RGB color functions (SETPIXELS, SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the
colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

! Build as QuickWin or Standard Graphics

USE IFQWIN

INTEGER(4) pixcolor, rseed

INTEGER(2) status

REAL rnd1, rnd2

LOGICAL(4) winstat

TYPE (windowconfig) wc

CALL GETTIM (status, status, status, INT2(rseed))

CALL SEED (rseed)

CALL RANDOM (rnd1)

CALL RANDOM (rnd2)

! Get the color index of a random pixel, normalized to
! be in the window. Then set current color to that
! pixel color.

winstat = GETWINDOWCONFIG(wc)

xnum = wc%numxpixels

ynum = wc%numypixels

pixcolor = GETPIXELRGB( INT2( rnd1*xnum ), INT2( rnd2*ynum ))

status = SETCOLORRGB (pixcolor)

END

Building Applications: Color Mixing

GETPIXELS (W*32, W*64)

**Graphics Subroutine:** Returns the color indexes of multiple pixels.

**Module**

USE IFQWIN

**Syntax**

CALL GETPIXELS (n, x, y, color)

- \( n \) (Input) INTEGER(4). Number of pixels to get. Sets the number of elements in the other arguments.
- \( x, y \) (Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to get.
- \( color \) (Output) INTEGER(2). Array to be filled with the color indexes of the pixels at \( x \) and \( y \).

GETPIXELS fills in the array \( color \) with color indexes of the pixels specified by the two input arrays \( x \) and \( y \). These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If the pixel is outside the clipping region, the value placed in the \( color \) array is undefined. Calls to GETPIXELS with \( n \) less than 1 are ignored. GETPIXELS is a much faster way to acquire multiple pixel color indexes than individual calls to GETPIXEL.

The range of possible pixel color index values is determined by the current video mode and palette, at most 256 colors. To access all system colors you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function such as SETPIXELSRGB and retrieve the value with GETPIXELSRGB, rather than a palette index with a non-RGB color function.
Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

See Also

- GETPIXELSRGB
- SETPIXELSRGB
- GETPIXEL
- SETPIXELS

GETPIXELSRGB (W*32, W*64)

Graphics Subroutine: Returns the Red-Green-Blue (RGB) color values of multiple pixels.

Module
USE IFQWIN

Syntax
CALL GETPIXELSRGB (n, x, y, color)

n (Input) INTEGER(4). Number of pixels to get. Sets the number of elements in the other argument arrays.

x, y (Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels.

color (Output) INTEGER(4). Array to be filled with RGB color values of the pixels at x and y.

GETPIXELS fills in the array color with the RGB color values of the pixels specified by the two input arrays x and y. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the values you retrieve with GETPIXELSRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:
Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETPIXELSRGB is a much faster way to acquire multiple pixel RGB colors than individual calls to GETPIXELRGB. GETPIXELSRGB returns an array of true color values of multiple pixels, set with SETPIXELSRGB, SETCOLORRGB, SETBKCOLORRGB, or SETTEXTCOLORRGB, depending on the pixels' positions and the current configuration of the screen.

SETPIXELSRGB (and the other RGB color selection functions SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB) sets colors to a color value chosen from the entire available range. The non-RGB color functions (SETPIXELS, SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

Building Applications: Color Mixing
GETPOS, GETPOSI8

Portability Functions: Return the current position of a file.

Module
USE IFPORT

Syntax
result = GETPOS (lunit)
result = GETPOSI8 (lunit)
lunit (Input) INTEGER(4). External unit number of a file. The value must be in the range 0 to 100 and the file must be connected.

Results
The result type is INTEGER(4) for GETPOS; INTEGER(8) for GETPOSI8. The result is the offset, in bytes, from the beginning of the file. If an error occurs, the result value is -1 and the following error code is returned in errno:
EINVAL: lunit is not a valid unit number, or is not open.

These functions are equivalent to FTELL, FTELL8.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

GETSTATUSFPQQ (W*32, W*64)

Portability Subroutine: Returns the floating-point processor status word.

Module
USE IFPORT

Syntax
CALL GETSTATUSFPQQ (status)

status (Output) INTEGER(2). Floating-point processor status word.
The floating-point status word shows whether various floating-point exception conditions have occurred. Intel® Fortran initially clears (sets to 0) all status flags, but after an exception occurs it does not reset the flags before performing additional floating-point operations. A status flag with a value of one thus shows there has been at least one occurrence of the corresponding exception. The following table lists the status flags and their values:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPSW$MSW_EM</td>
<td>Z'003F'</td>
<td>Status Mask (set all flags to 1)</td>
</tr>
<tr>
<td>FPSW$INVALID</td>
<td>Z'0001'</td>
<td>An invalid result occurred</td>
</tr>
<tr>
<td>FPSW$DENORMAL</td>
<td>Z'0002'</td>
<td>A denormal (very small number) occurred</td>
</tr>
<tr>
<td>FPSW$ZERODIVIDE</td>
<td>Z'0004'</td>
<td>A divide by zero occurred</td>
</tr>
<tr>
<td>FPSW$OVERFLOW</td>
<td>Z'0008'</td>
<td>An overflow occurred</td>
</tr>
<tr>
<td>FPSW$UNDERFLOW</td>
<td>Z'0010'</td>
<td>An underflow occurred</td>
</tr>
<tr>
<td>FPSW$INEXACT</td>
<td>Z'0020'</td>
<td>Inexact precision occurred</td>
</tr>
</tbody>
</table>

You can use a logical comparison on the status word returned by GETSTATUSFPQQ to determine which of the six floating-point exceptions listed in the table has occurred.

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. By default, all exception traps are disabled. Exceptions can be enabled and disabled by clearing and setting the flags with SETCONTROLFPQQ. You can use GETCONTROLFPQQ to determine which exceptions are currently enabled and disabled.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues. You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ.

If errors on floating-point exceptions are enabled (by clearing the flags to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause run-time errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

For a full discussion of the floating-point status word, exceptions, and error handling, see *Building Applications: The Floating-Point Environment Overview*. 
**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB

**Example**

! Program to demonstrate GETSTATUSFPQQ

USE IFPORT

INTEGER(2) status

CALL GETSTATUSFPQQ(status)

! check for divide by zero

IF (IAND(status, FPSW$ZERODIVIDE) .NE. 0) THEN
  WRITE (*,*) 'Divide by zero occurred. Look &
  for NaN or signed infinity in resultant data.'
END IF

END

**GETSTRQQ**

*Run-Time Function: Reads a character string from the keyboard using buffered input.*

**Module**

USE IFCORE

**Syntax**

result = GETSTRQQ (buffer)

*buffer* (Output) Character*(*). Character string returned from keyboard, padded on the right with blanks.
Results
The result type is INTEGER(4). The result is the number of characters placed in buffer.
The function does not complete until you press Return or Enter.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
! Program to demonstrate GETSTRQQ
USE IPCORE
USE IFPORT
INTEGER(4) length, result
CHARACTER(80) prog, args
WRITE ('*, '(A, \')' ) ' Enter program to run: '
length = GETSTRQQ (prog)
WRITE ('*, '(A, \')' ) ' Enter arguments: '
length = GETSTRQQ (args)
result = RUNQQ (prog, args)
IF (result .EQ. -1) THEN
  WRITE (*,* ) 'Couldn''t run program'
ELSE
  WRITE (*, '(A, Z4, A)') 'Return code : ', result, 'h'
END IF
END

See Also

• GETCHARQQ
• PEEKCHARQQ
GETTEXTCOLOR (W*32, W*64)

Graphics Function: Returns the current text color index.

Module
USE IFQWIN

Syntax
result = GETTEXTCOLOR( )

Results
The result type is INTEGER(2). It is the current text color index.

GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR affects text output with OUTTEXT, WRITE, and PRINT. The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and SETCOLORRGB.

The default text color index is 15, which is associated with white unless the user remaps the palette.

NOTE. The GETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the GetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$GetTextColor. For more information, see Building Applications: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

• SETTEXTCOLOR

Building Applications: Using Text Colors

GETTEXTCOLORRGB (W*32, W*64)

**Graphics Function:** Returns the Red-Green-Blue (RGB) value of the current text color (used with OUTTEXT, WRITE and PRINT).

**Module**
USE IFQWIN

**Syntax**
result = GETTEXTCOLORRGB( )

**Results**
The result type is INTEGER(4). It is the RGB value of the current text color.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B G G G G G G R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFF' full-intensity for all three, resulting in bright white.

GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB. The RGB color value used for graphics is set and returned with SETCOLORRGB and GETCOLORRGB. SETCOLORRGB controls the color used by the graphics function OUTGTEXT, while SETTEXTCOLORRGB controls the color used by all other text output functions. The RGB background color value for both text and graphics is set and returned with SETBKCOLORRGB and GETBKCOLORRGB.
SETTEXTCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB, and
SETCOLORRGB) sets the color to a color value chosen from the entire available range. The
non-RGB color functions (SETTEXTCOLOR, SETBKCOLOR, and SETCOLOR) use color indexes
rather than true color values. If you use color indexes, you are restricted to the colors available
in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating
262,144 (256K) colors or more. To access any available color, you need to specify an explicit
RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) oldtextc, oldbackc, temp
TYPE (rccoord) curpos
! Save color settings
oldtextc = GETTEXTCOLORRGB()
oldbackc = GETBKCOLORRGB()
CALL CLEARSCREEN( $GCLEARSCREEN )
! Reset colors
temp = SETTEXTCOLORRGB(Z'00FFFF') ! full red + full green
      ! = full yellow text
temp = SETBKCOLORRGB(Z'FF0000') ! blue background
CALL SETTEXTPOSITION( INT2(4), INT2(15), curpos)
CALL OUTTEXT( 'Hello, world')
! Restore colors
temp = SETTEXTCOLORRGB(oldtextc)
temp = SETBKCOLORRGB(oldbackc)
END
See Also

- GETTEXTCOLOR

Building Applications: Using Text Colors

**GETTEXTPosition (W*32, W*64)**

*Graphics Subroutine: Returns the current text position.*

**Module**

USE IFQWIN

**Syntax**

CALL GETTEXTPosition (t)

(\textit{Output}) Derived type \textit{rccord}. Current text position. The derived type \textit{rccord} is defined in IFQWIN.F90 as follows:

\begin{verbatim}
TYPE rccord
    INTEGER(2) row  ! Row coordinate
    INTEGER(2) col  ! Column coordinate
END TYPE rccord
\end{verbatim}

The text position given by coordinates (1, 1) is defined as the upper-left corner of the text window. Text output from the OUTTEXT function (and WRITE and PRINT statements) begins at the current text position. Font text is not affected by the current text position. Graphics output, including OUTGTEXT output, begins at the current graphics output position, which is a separate position returned by GETCURRENTPOSITION.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example
! Build as QuickWin or Standard Graphics
USE IFQWIN
    TYPE (rcoord) textpos
    CALL GETTEXTPOSITION (textpos)
END

See Also
• G
• SETTEXTPOSITION
• GETCURRENTPOSITION
• OUTTEXT
• WRITE
• SETTEXTWINDOW

GETTEXTWINDOW (W*32, W*64)

Graphics Subroutine: Finds the boundaries of
the current text window.

Module
USE IFQWIN

Syntax
CALL GETTEXTWINDOW (r1,c1,r2,c2)

r1, c1       (Output) INTEGER(2). Row and column coordinates for upper-left corner of the text window.
r2, c2       (Output) INTEGER(2). Row and column coordinates for lower-right corner of the text window.

Output from OUTTEXT and WRITE is limited to the text window. By default, this is the entire window, unless the text window is redefined by SETTEXTWINDOW.
The window defined by SETTEXTWINDOW has no effect on output from OUTGTEXT.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as QuickWin or Standard Graphics

USE IFQWIN

INTEGER(2) top, left, bottom, right

DO i = 1, 10
    WRITE(*,*) "Hello, world"
END DO

! Save text window position
CALL GETTEXTWINDOW (top, left, bottom, right)

! Scroll text window down seven lines
CALL SCROLLTEXTWINDOW (INT2(-7))

! Restore text window
CALL SETTEXTWINDOW (top, left, bottom, right)

WRITE(*,*) "At beginning again"
END

- SECNDS portability routine
- TIME portability routine
- TIMEF

**GETTIMEOFDAY**

*Portability Subroutine:* Returns seconds and microseconds since 00:00 Jan 1, 1970.

**Module**

USE IFPORT

**Syntax**

CALL GETTIMEOFDAY (ret, err)

*ret* (Output) INTEGER(4). One-dimensional array with 2 elements used to contain numeric time data. The elements of *ret* are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ret(1)</td>
<td>Seconds</td>
</tr>
<tr>
<td>ret(2)</td>
<td>Microseconds</td>
</tr>
</tbody>
</table>

*err* (Output) INTEGER(4).

If an error occurs, *err* contains a value equal to -1 and array *ret* contains zeros.

On Windows* systems, this subroutine has millisecond precision, and the last three digits of the returned value are not significant.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**GETUID**

*Portability Function:* Returns the user ID of the calling process.

**Module**

USE IFPORT
Syntax

result = GETUID( )

Results
The result type is INTEGER(4). The result corresponds to the user identity under which the program is running. The result is returned as follows:

- On Windows* systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.
  Note that on Windows systems, domain accounts and local accounts can overlap.
- On Linux* and Mac OS* X systems, this function returns the user identity for the current process.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
integer(4) istat
ISTAT = GETUID( )

GETUNITQQ (W*32, W*64)

QuickWin Function: Returns the unit number corresponding to the specified Windows* handle.

Module
USE IFQWIN

Syntax

result = GETUNITQQ (whandle)

whandle (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. The Windows handle to the window; this is a unique ID.
Results

The result type is INTEGER(4). The result is the unit number corresponding to the specified Windows handle. If whandle does not exist, it returns -1.

This routine is the inverse of GETHWNDQQ.

Compatibility

Building Applications: Using QuickWin Overview

GETVIEWCOORD, GETVIEWCOORD_W (W*32, W*64)

Graphics Subroutines: Translate physical coordinates or window coordinates to viewport coordinates.

Module

USE IFQWIN

Syntax

CALL GETVIEWCOORD (x, y, t)
CALL GETVIEWCOORD_W (wx, wy, wt)

x, y
(Input) INTEGER(2). Physical coordinates to be converted to viewport coordinates.

t
(Output) Derived type xycoord. Viewport coordinates. The xycoord derived type is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
  INTEGER(2) xcoord ! x-coordinate
  INTEGER(2) ycoord ! y-coordinate
END TYPE xycoord
```
wx, wy  (Input) REAL(8). Window coordinates to be converted to viewport coordinates.

wt  (Output) Derived type wxycoord. Window coordinates. The derived type wxycoord is defined in IFQWIN.F90 as follows:

```
TYPE wxycoord
  REAL(8) wx  ! x-coordinate
  REAL(8) wy  ! y-coordinate
END TYPE wxycoord
```

Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Physical coordinates refer to the whole screen. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area. For a more complete discussion of coordinate systems, see Building Applications: Understanding Coordinate Systems Overview.

Compatibility

GETWINDOWCONFIG (W*32, W*64)

QuickWin Function: Returns the properties of the current window.

Module

USE IFQWIN
Syntax

result = GETWINDOWCONFIG (wc)
(Output) Derived type windowconfig. Contains window properties. The windowconfig derived type is defined in IFQWIN.F90 as follows:

```fortran
TYPE windowconfig
  INTEGER(2) numxpixels ! Number of pixels on x-axis
  INTEGER(2) numypixels ! Number of pixels on y-axis
  INTEGER(2) numtextcols ! Number of text columns available
  INTEGER(2) numtextrows ! Number of text rows available
  INTEGER(2) numcolors ! Number of color indexes
  INTEGER(4) fontsize ! Size of default font. Set to QWIN$EXTENDFONT when specifying extended attributes, in which case extendfontsize sets the font size
  CHARACTER(80) title ! The window title
  INTEGER(2) bitsperpixel ! The number of bits per pixel
  INTEGER(2) numvideopages ! Unused
  INTEGER(2) mode ! Controls scrolling mode
  INTEGER(2) adapter ! Unused
  INTEGER(2) monitor ! Unused
  INTEGER(2) memory ! Unused
  INTEGER(2) environment ! Unused

! The next three parameters provide extended font attributes.
! CHARACTER(32) extendfontname ! The name of the desired font
```

wc
INTEGER(4) extendfontsize  ! Takes the same values as
! fontsize,
! when fontsize is set to
! QWIN$EXTENDFONT

INTEGER(4) extendfontattributes  ! Font attributes such as
! bold
! and italic

END TYPE windowconfig

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE. (for example, if there is no active child window).

GETWINDOWCONFIG returns information about the active child window. If you have not set the window properties with SETWINDOWCONFIG, GETWINDOWCONFIG returns default window values.

A typical set of values would be 1024 $x$ pixels, 768 $y$ pixels, 128 text columns, 48 text rows, and a font size of 8x16 pixels. The resolution of the display and the assumed font size of 8x16 pixels generates the number of text rows and text columns. The resolution (in this case, 1024 $x$ pixels by 768 $y$ pixels) is the size of the virtual window. To get the size of the physical window visible on the screen, use GETWSIZEQQ. In this case, GETWSIZEQQ returned the following values: (0,0) for the x and y position of the physical window, 25 for the height or number of rows, and 71 for the width or number of columns.

The number of colors returned depends on the video drive. The window title defaults to "Graphic1" for the default window. All of these values can be changed with SETWINDOWCONFIG.

Note that the bitsperpixel field in the windowconfig derived type is an output field only, while the other fields return output values to GETWINDOWCONFIG and accept input values from SETWINDOWCONFIG.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

!Build as QuickWin or Standard Graphics App.

USE IFQWIN

LOGICAL(4) status

TYPE (windowconfig) wc

status = GETWINDOWCONFIG(wc)

IF(wc%numtextrows .LT. 10) THEN
  wc%numtextrows = 10

GETWRITEMODE (W*32, W*64)

Graphics Function: Returns the current logical write mode, which is used when drawing lines with the LINETO, POLYGON, and RECTANGLE functions.

Module
USE IFQWIN

Syntax
result = GETWRITEMODE( )

Results
The result type is INTEGER(2). The result is the current write mode. Possible return values are:

- $GPSET - Causes lines to be drawn in the current graphics color. (default)
- $GAND - Causes lines to be drawn in the color that is the logical AND of the current graphics color and the current background color.
- $GOR - Causes lines to be drawn in the color that is the logical OR of the current graphics color and the current background color.
- $GPRESET - Causes lines to be drawn in the color that is the logical NOT of the current graphics color.
- $GXOR - Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the current graphics color and the current background color.

The default value is $GPSET. These constants are defined in IFQWIN.F90.

The write mode is set with SETWRITEMODE.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as QuickWin or Standard Graphics App.

    USE IFQWIN
    INTEGER(2) mode
    mode = GETWRITEMODE()
    END

*Building Applications*: Setting Figure Properties

**GETWSIZEQQ (W*32, W*64)**

*QuickWin Function*: Returns the size and position of a window.

Module

USE IFQWIN

Syntax

```fortran
result = GETWSIZEQQ (unit, iraq, winfo)
```

(Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5 and 6 refer to the default startup window only if you have not explicitly opened them with the OPEN statement. To access
information about the frame window (as opposed to a child window), set unit to the symbolic constant QWIN$FRAMEWINDOW, defined in IFQWIN.F90.

\textit{ireq} \\
(Input) INTEGER(4). Specifies what information is obtained. The following symbolic constants, defined in IFQWIN.F90, are available:

- QWIN$SIZEMAX - Gets information about the maximum window size.
- QWIN$SIZECURR - Gets information about the current window size.

\textit{winfo} \\
(Output) Derived type qwinfo. Physical coordinates of the window's upper-left corner, and the current or maximum height and width of the window's client area (the area within the frame). The derived type qwinfo is defined in IFQWIN.F90 as follows:

\begin{verbatim}
TYPE QWINFO
  INTEGER(2) TYPE ! request type (controls
                   ! SETWSIZEQQ)
  INTEGER(2) X ! x coordinate for upper left
  INTEGER(2) Y ! y coordinate for upper left
  INTEGER(2) H ! window height
  INTEGER(2) W ! window width
END TYPE QWINFO
\end{verbatim}

\textbf{Results}

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.

The height and width returned for a frame window reflects the size in pixels of the client area excluding any borders, menus, and status bar at the bottom of the frame window. You should adjust the values used in SETWSIZEQQ to take this into account.

The client area is the area actually available to place child windows.

GMTIME

Portability Subroutine: Returns the Greenwich mean time in an array of time elements.

Module
USE IFPORT

Syntax
CALL GMTIME (stime, tarray)

stime
(Input) INTEGER(4). Numeric time data to be formatted. Number of seconds since 00:00:00 Greenwich mean time, January 1, 1970.

tarray
(Output) INTEGER(4). One-dimensional array with 9 elements used to contain numeric time data. The elements of tarray are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tarray(1)</td>
<td>Seconds (0-61, where 60-61 can be returned for leap seconds)</td>
</tr>
<tr>
<td>tarray(2)</td>
<td>Minutes (0-59)</td>
</tr>
<tr>
<td>tarray(3)</td>
<td>Hours (0-23)</td>
</tr>
<tr>
<td>tarray(4)</td>
<td>Day of month (1-31)</td>
</tr>
</tbody>
</table>
CAUTION. This subroutine may cause problems with the year 2000. Use DATE_AND_TIME instead.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
use IFPORT
integer(4) stime, timearray(9)
! initialize stime to number of seconds since
! 00:00:00 GMT January 1, 1970
stime = time()
CALL GMTIME (stime, timearray)
print *, timearray
end

GOTO - Assigned

Statement: Transfers control to the statement whose label was most recently assigned to a variable. This feature has been deleted in Fortran 95; it was obsolescent in Fortran 90. Intel Fortran fully supports features deleted in Fortran 95.

Syntax

GOTO var[[ ,] ( label-list)]

var Is a scalar integer variable.

label-list Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the assigned GO TO statement. The same label can appear more than once in this list.

The variable must have a statement label value assigned to it by an ASSIGN statement (not an arithmetic assignment statement) before the GO TO statement is executed.

If a list of labels appears, the statement label assigned to the variable must be one of the labels in the list.

Both the assigned GO TO statement and its associated ASSIGN statement must be in the same scoping unit.

Example

The following example is equivalent to GO TO 200:

ASSIGN 200 TO IGO
GO TO IGO

The following example is equivalent to GO TO 450:

ASSIGN 450 TO IBEG
GO TO IBEG, (300,450,1000,25)

The following example shows an invalid use of an assigned variable:

ASSIGN 10 TO I
J = I
GO TO J
In this case, variable J is not the variable assigned to, so it cannot be used in the assigned GO TO statement.

The following shows another example:

\[
\begin{align*}
\text{ASSIGN 10 TO } n \\
\text{GOTO } n \\
10 \text{ CONTINUE}
\end{align*}
\]

The following example uses an assigned GOTO statement to check the value of view:

\[
\begin{align*}
\text{C Show user appropriate view of data depending on} \\
\text{C security clearance.} \\
\text{GOTO view (100, 200, 400)}
\end{align*}
\]

See Also
- G
- Obsolescent Features in Fortran 90
- GOTO - Computed GOTO
- GOTO - Unconditional GOTO
- Execution Control

**GOTO - Computed**

*Statement:* Transfers control to one of a set of labeled branch target statements based on the value of an expression. It is an obsolescent feature in Fortran 95.

**Syntax**

\[
\text{GOTO (label-list) [ ,] expr}
\]

- **label-list**
  Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the computed GO TO statement. (Also called the transfer list.) The same label can appear more than once in this list.

- **expr**
  Is a scalar numeric expression in the range 1 to n, where n is the number of statement labels in label-list. If necessary, it is converted to integer data type.
When the computed GO TO statement is executed, the expression is evaluated first. The value
of the expression represents the ordinal position of a label in the associated list of labels. Control
is transferred to the statement identified by the label. For example, if the list contains
(30,20,30,40) and the value of the expression is 2, control is transferred to the statement
identified with label 20.

If the value of the expression is less than 1 or greater than the number of labels in the list,
control is transferred to the next executable statement or construct following the computed
GO TO statement.

**Example**

The following example shows valid computed GO TO statements:

```
GO TO (12,24,36), INDEX
GO TO (320,330,340,350,360), SITU(J,K) + 1
```

The following shows another example:

```
next = 1

C The following statement transfers control to statement 10:
C

GOTO (10, 20) next

... 10 CONTINUE

... 20 CONTINUE
```

**See Also**
- G
- obsolescent feature
- GOTO - Unconditional GOTO
- Execution Control
**GOTO - Unconditional**

**Statement:** Transfers control to the same branch target statement every time it executes.

**Syntax**

```
GO TO label
```

*label* is the label of a valid branch target statement in the same scoping unit as the GO TO statement.

The unconditional GO TO statement transfers control to the branch target statement identified by the specified label.

**Example**

The following are examples of GO TO statements:

```
GO TO 7734
GO TO 99999
```

The following shows another example:

```
integer(2) in
10  print *, 'enter a number from one to ten: '
    read *, in
    select case (in)
    case (1:10)
      exit
    case default
      print *, 'wrong entry, try again'
      goto 10
    end select
```

GRSTATUS (W*32, W*64)

*Graphics Function:* Returns the status of the most recently used graphics routine.

**Module**

USE IFQWIN

**Syntax**

\[ \text{result} = \text{GRSTATUS}(\quad) \]

**Results**

The result type is INTEGER(2). The result is the status of the most recently used graphics function.

Use GRSTATUS immediately following a call to a graphics routine to determine if errors or warnings were generated. Return values less than 0 are errors, and values greater than 0 are warnings.

The following symbolic constants are defined in the IFQWIN.F90 module file for use with GRSTATUS:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>$GRFILEWRITEERROR</td>
<td>Error writing bitmap file</td>
</tr>
<tr>
<td>$GRFILEOPENERROR</td>
<td>Error opening bitmap file</td>
</tr>
<tr>
<td>$GRIMAGEREADERERROR</td>
<td>Error reading image</td>
</tr>
<tr>
<td>$GRBITMAPDISPLAYERROR</td>
<td>Error displaying bitmap</td>
</tr>
<tr>
<td>$GRBITMAPTOOLARGE</td>
<td>Bitmap too large</td>
</tr>
<tr>
<td>$GRIMPROPERBITMAPFORMAT</td>
<td>Improper format for bitmap file</td>
</tr>
<tr>
<td>$GRFILEREADERERROR</td>
<td>Error reading file</td>
</tr>
<tr>
<td>$GRNOBITMAPFILE</td>
<td>No bitmap file</td>
</tr>
<tr>
<td>$GRINVALIDIMAGEBUFFER</td>
<td>Image buffer data inconsistent</td>
</tr>
</tbody>
</table>

2814
Meaning

- **$GRINSUFFICIENTMEMORY**: Not enough memory to allocate buffer or to complete a fill operation
- **$GRINVALIDPARAMETER**: One or more parameters invalid
- **$GRMODENOTSUPPORTED**: Requested video mode not supported
- **$GRERROR**: Graphics error
- **$GROK**: Success
- **$GRNOOUTPUT**: No action taken
- **$GRCLIPPED**: Output was clipped to viewport
- **$GRPARAMETERALTERED**: One or more input parameters was altered to be within range, or pairs of parameters were interchanged to be in the proper order

After a graphics call, compare the return value of GRSTATUS to $GROK. to determine if an error has occurred. For example:

```fortran
IF ( GRSTATUS .LT. $GROK ) THEN
    ! Code to handle graphics error goes here
ENDIF
```

The following routines cannot give errors, and they all set GRSTATUS to $GROK:

<table>
<thead>
<tr>
<th>Routine</th>
<th>Routine</th>
<th>Routine</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISPLAYCURSOR</td>
<td>GETCOLORRGB</td>

*Building Applications: Setting the Font and Displaying Text*
**HOSTNAM**

*Portability Function:* Returns the current host computer name. This function can also be specified as HOSTNM.

**Module**

USE IFPORT

**Syntax**

```
result = HOSTNAM (name)
```

- **name** (Output) Character*(*) . Name of the current host. Should be at least as long as MAX_HOSTNAM_LENGTH + 1. MAX_HOSTNAM_LENGTH is defined in the IFPORT module.

**Results**

The result type is INTEGER(4). The result is zero if successful. If name is not long enough to contain all of the host name, the function truncates the host name and returns -1.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```
use IFPORT
character(MAX_HOSTNAM_LENGTH + 1) hostname
integer(4) istat
ISTAT = HOSTNAM (hostname)
```
HUGE

*Inquiry Intrinsic Function (Generic):* Returns the largest number in the model representing the same type and kind parameters as the argument.

**Syntax**

```
result = HUGE (x)
```

*(Input) Must be of type integer or real; it can be scalar or array valued.*

**Results**

The result is a scalar of the same type and kind parameters as `x`. If `x` is of type integer, the result has the value `r^q - 1`. If `x` is of type real, the result has the value `(1 - b^p)b^e_{\text{max}}`.

Integer parameters `r` and `q` are defined in *Model for Integer Data*; real parameters `b`, `p`, and `e_{\text{max}}` are defined in *Model for Real Data*.

**Example**

If `X` is of type REAL(4), `HUGE (X)` has the value `(1 - 2^{-24}) x 2^{128}`.

**See Also**

- H to I
- TINY
- Data Representation Models

IACHAR

*Elemental Intrinsic Function (Generic):* Returns the position of a character in the ASCII character set, even if the processor’s default character set is different. In Intel® Fortran, IACHAR is equivalent to the ICHAR function.

**Syntax**

```
result = IACHAR (c [, kind])
```

*(Input) Must be of type character of length 1.*

*c* (Input; optional) Must be a scalar integer initialization expression.
Results

The result type is integer. If \textit{kind} is present, the kind parameter of the result is that specified by \textit{kind}; otherwise, the kind parameter of the result is that of default integer. If \textit{c} is in the ASCII collating sequence, the result is the position of \textit{c} in that sequence and satisfies the inequality \(0 \leq \text{IACHAR}(c) \leq 127\).

The results must be consistent with the LGE, LGT, LLE, and LLT lexical comparison functions. For example, if LLE(C, D) is true, IACHAR(C) \leq IACHAR(D) is also true.

Example

IACHAR ( 'Y' ) has the value 89.
IACHAR ( '%' ) has the value 37.

\textbf{IAND}

\textit{Elemental Intrinsic Function (Generic):}

Performs a logical AND on corresponding bits. \textit{This function can also be specified as AND.}

\textbf{Syntax}

\begin{verbatim}
result = IAND (i, j)
\end{verbatim}

\begin{itemize}
\item \textbf{i} (Input) Must be of type integer or of type logical (which is treated as an integer).
\end{itemize}
The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIAND</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIAND</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JIAND</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIAND</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

1Or HIAND.

Example

IAND (2, 3) has the value 2.
IAND (4, 6) has the value 4.

- IOR
IARGC

_Inquiry Intrinsic Function (Specific):_ Returns the index of the last command-line argument. It cannot be passed as an actual argument. This function can also be specified as IARG or NUMARG.

**Syntax**

\[ \text{result} = \text{IARGC}() \]

**Results**

The result type is INTEGER(4). The result is the index of the last command-line argument, which is also the number of arguments on the command line. The command is not included in the count. For example, IARGC returns 3 for the command-line invocation of `PROG1 -g -c -a`.

IARGC returns a value that is 1 less than that returned by NARGS.

**Example**

```fortran
integer(4) no_of_arguments
no_of_arguments = IARGC()
print *, 'total command line arguments are ', no_of_arguments
```

For a command-line invocation of `PROG1 -g -c -a`, the program above prints:

total command line arguments are 3

IBCHNG

**Elemental Intrinsic Function (Generic):**
Reverses the value of a specified bit in an integer.

**Syntax**

\[
\text{result} = \text{IBCHNG}(i, pos)
\]

- \(i\) (Input) Must be of type integer or of type logical (which is treated as an integer). This argument contains the bit to be reversed.
- \(pos\) (Input) Must be of type integer. This argument is the position of the bit to be changed. The rightmost (least significant) bit of \(i\) is in position 0.

**Results**
The result type is the same as \(i\). The result is equal to \(i\) with the bit in position \(pos\) reversed.
For more information, see Bit Functions.

**Example**

```fortran
INTEGER J, K
J = IBCHNG(10, 2)  ! returns 14 = 1110
K = IBCHNG(10, 1)  ! returns 8 = 1000
```

- ISHL
- ISHFT
- NOT
**IBCLR**

*Elemental Intrinsic Function (Generic): Clears one bit to zero.*

**Syntax**

\[ \text{result} = \text{IBCLR} \left( i, pos \right) \]

*i*  
(Input) Must be of type integer or of type logical (which is treated as an integer).

*pos*  
(Input) Must be of type integer. It must not be negative and it must be less than \(\text{BIT\_SIZE}(i)\). The rightmost (least significant) bit of \(i\) is in position 0.

**Results**

The result type is the same as \(i\). The result has the value of the sequence of bits of \(i\), except that bit \(pos\) of \(i\) is set to zero.

For more information, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BBCLR</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIBCLR(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>

<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIBCLR</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

\(^1\) Or HBCLR.

**Example**

IBCLR (18, 1) has the value 16.

If \(V\) has the value (1, 2, 3, 4), the value of IBCLR (\(POS = V, I = 15\)) is (13, 11, 7, 15).
The following shows another example:

```
INTEGER J, K
J = IBCLR(7, 1) ! returns 5 = 0101
K = IBCLR(5, 1) ! returns 5 = 0101
```

**IBITS**

*Elemental Intrinsic Function (Generic):*

*Extracts a sequence of bits (a bit field).*

**Syntax**

```
result = IBITS (i,pos,len)
```

- *i*  
  (Input) Must be of type integer.

- *pos*  
  (Input) Must be of type integer. It must not be negative and *pos* + *len* must be less than or equal to BIT_SIZE(*i*). The rightmost (least significant) bit of *i* is in position 0.

- *len*  
  (Input) Must be of type integer. It must not be negative.

**Results**

The result type is the same as *i*. The result has the value of the sequence of *len* bits in *i*, beginning at *pos*, right-adjusted and with all other bits zero.
For more information, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

- ISHFTC
- MVBITS

**IBSET**

*Elemental Intrinsic Function (Generic):* Sets one bit to 1.

**Syntax**

\[ \text{result} = \text{IBSET} (i, \text{pos}) \]
$i$  (Input) Must be of type integer or of type logical (which is treated as an integer).

$pos$  (Input) Must be of type integer. It must not be negative and it must be less than $\text{BIT\_SIZE}(i)$.
The rightmost (least significant) bit of $i$ is in position 0.

**Results**
The result type is the same as $i$. The result has the value of the sequence of bits of $i$, except that bit $pos$ of $i$ is set to 1.

For more information, see Bit Functions.
The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIBSET</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

$^1$Or HBSET.

**Example**
IBSET (8, 1) has the value 10.
If $V$ has the value (1, 2, 3, 4), the value of IBSET (POS = $V$, I = 2) is (2, 6, 10, 18).
The following shows another example:

```
INTEGER I
I = IBSET(8, 2) ! returns 12 = 1100
```

**See Also**
- H to I
- BTEST
- IAND
Elemental Intrinsic Function (Generic):
Returns the position of a character in the processor's character set.

Syntax

\[
\text{result} = \text{ICHAR} (c [, \text{kind}])
\]

* c (Input) Must be of type character of length 1.
* kind (Input; optional) Must be a scalar integer initialization expression.

Results

The result type is integer. If \( \text{kind} \) is present, the kind parameter of the result is that specified by \( \text{kind} \); otherwise, the kind parameter of the result is that of default integer.

The result value is the position of \( c \) in the processor's character set. \( c \) is in the range zero to \( n - 1 \), where \( n \) is the number of characters in the character set.

For any characters C and D (capable of representation in the processor), C \( \leq \) D is true only if ICHAR(C) \( \leq \) ICHAR(D) is true, and C \( = \) D is true only if ICHAR(C) \( = \) ICHAR(D) is true.

<table>

<td>INTEGER(8)</td>
</tr>
</tbody>
</table>
### Specific Name | Argument Type | Result Type
--- | --- | ---

1. This specific function cannot be passed as an actual argument.

**Example**

ICHAR ( 'W' ) has the value 87.

ICHAR ( '#' ) has the value 35.

### IDATE Intrinsic Procedure

**Intrinsic Subroutine (Generic):** *Returns three integer values representing the current month, day, and year. IDATE can be used as an intrinsic subroutine or as a portability subroutine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.*

**Syntax**

CALL IDATE (i, j, k)

- \( i \) (Output) Must be of type integer. It is the current month.
- \( j \) (Output) Must be of type integer with the same kind type parameter as \( i \). It is the current day.
- \( k \) (Output) Must be of type integer with the same kind type parameter as \( i \). It is the current year.

The current month is returned in \( i \); the current day in \( j \). The last two digits of the current year are returned in \( k \).

**CAUTION.** The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.
Example
If the current date is September 16, 1999, the values of the integer variables upon return are:
I = 9, J = 16, and K = 99.

See Also
• H to I
• DATE intrinsic procedure
• DATE_AND_TIME
• GETDAT
• IDATE portability routine

IDATE Portability Routine

Portability Subroutine: Returns the month, day, and year of the current system. IDATE can be used
as an intrinsic subroutine or as a portability subroutine. It is an intrinsic procedure unless you
specify USE IFPORT.

Module
USE IFPORT

Syntax
CALL IDATE (i, j, k)
-or-
CALL IDATE (iarray)

i
(Output) INTEGER(4). Is the current system month.

j
(Output) INTEGER(4). Is the current system day.

k
(Output) INTEGER(4). Is the current system year as an offset from
1900.

iarray
(Output) INTEGER(4). Is a three-element array that holds day as
element 1, month as element 2, and year as element 3. The month
is between 1 and 12. The year is greater than or equal to 1969
and is returned as 2 digits.
CAUTION. The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

use IFPORT

integer(4) imonth, iday, iyear, datarray(3)
! If the date is July 11, 1999:
    CALL IDATE(IMONTH, IDAY, IYEAR)
! sets IMONTH to 7, IDAY to 11 and IYEAR to 99.
    CALL IDATE (DATARRAY)
! datarray is (/11,7,99/)

See Also

- H to I
- DATE portability routine
- DATE_AND_TIME
- GETDAT
- IDATE intrinsic procedure

IDATE4

Portability Subroutine: Returns the month, day, and year of the current system.

Module

USE IFPORT

Syntax

CALL IDATE4 (i,j,k)
-or-
CALL IDATE4 (iarray)
\(i\) (Output) INTEGER(4). The current system month.

\(j\) (Output) INTEGER(4). The current system day.

\(k\) (Output) INTEGER(4). The current system year as an offset from 1900.

\(iarray\) (Output) INTEGER(4). A three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is returned as an offset from 1900, if the year is less than 2000. For years greater than or equal to 2000, this element simply returns the integer year, such as 2003.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**IDENT**

**General Compiler Directive:** Specifies a string that identifies an object module. The compiler places the string in the identification field of an object module when it generates the module for each source program unit.

**Syntax**

```
cDEC$ IDENT string
```

\(c\) Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

\(string\) Is a character constant containing printable characters. The number of characters is limited by the length of the source line.

Only the first IDENT directive is effective; the compiler ignores any additional IDENT directives in a program unit or module.

**IDFLOAT**

**Portability Function:** Converts an INTEGER(4) argument to double-precision real type.

**Module**

USE IFPORT
Syntax

result = IDFLOAT (i)

i  (Input) Must be of type INTEGER(4).

Results

The result type is double-precision real (REAL(8) or REAL*8).

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also

- H to I
- DFLOAT

IEEE_CLASS

Elemental Module Intrinsic Function (Generic): Returns the IEEE class.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_CLASS (x)

x  (Input) Must be of type REAL.

Results

The result is of type TYPE(IEEE_CLASS_TYPE). The result value is one of the following:

<table>
<thead>
<tr>
<th>IEEE_SIGNALING_NAN</th>
<th>IEEE_NEGATIVE_NORMAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_QUITE_NAN</td>
<td>IEEE_POSITIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_POSITIVE_INF</td>
<td>IEEE_NEGATIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_NEGATIVE_INF</td>
<td>IEEE_POSITIVE_ZERO</td>
</tr>
</tbody>
</table>
IEEE_CLASS does not return IEEE_OTHER_VALUE in Intel Fortran.

Example
IEEE_CLASS(1.0) has the value IEEE_POSITIVE_NORMAL.

**IEEE_COPY_SIGN**

*Elemental Module Intrinsic Function (Generic)*: Returns an argument with a copied sign. This is equivalent to the IEEE copysign function.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

result = IEEE_COPY_SIGN (x, y)

*x*  
(Input) Must be of type REAL.

*y*  
(Input) Must be of type REAL.

**Results**

The result type is the same as *x*. The result has the value *x* with the sign of *y*. This is true even for IEEE special values, such as NaN or infinity.

The flags information is returned as a set of 1-bit flags.

**Example**

The value of IEEE_COPY_SIGN (X, 3.0) is ABS (X), even when X is NaN.

**IEEE_GET_FLAG**

*Elemental Module Intrinsic Subroutine (Generic)*: Returns whether an exception flag is signaling.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC
Syntax

CALL IEEE_GET_FLAG (flag, flag_value)

flag (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one
of the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
IEEE_OVERFLOW, or IEEE_UNDERFLOW.

flag_value (Output) Must be of type default logical. If the exception in 'flag'
is signaling, the result is true; otherwise, false.

Example

Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use module IEEE_ARITHMETIC
LOGICAL ON
...
CALL IEEE_GET_FLAG(IEEE_INVALID, ON)

If flag IEEE_INVALID is signaling, the value of ON is true; if it is quiet, the value of ON is false.

IEEE_GET_HALTING_MODE

Elemental Module Intrinsic Subroutine
(Generic): Stores the halting mode for an
exception.

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

CALL IEEE_GET_HALTING_MODE (flag, halting)

flag (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one
of the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
IEEE_OVERFLOW, or IEEE_UNDERFLOW.

halting (Output) Must be of type default logical. If the exception in "flag"
causes halting, the result is true; otherwise, false.
Example
Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS

LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT) ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT) ! Restores halting
```

**IEEE_GET_ROUNDING_MODE**

*Intrinsic Module Subroutine (Generic): Stores the current IEEE rounding mode.*

**Module**

```fortran
USE, INTRINSIC :: IEEE_ARITHMETIC
```

**Syntax**

```fortran
CALL IEEE_GET_ROUNDING_MODE (round_value)
```

*round_value* (Output) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It returns one of the following IEEE floating-point rounding values: IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, or IEEE_UP; otherwise, IEEE_OTHER. The result can only be used if IEEE_SET_ROUNDING_MODE is invoked.
**Example**

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_ARITHMETIC

TYPE(IEEE_ROUND_TYPE) ROUND

... CALL IEEE_GET_ROUNDING_MODE(ROUND) ! Stores the rounding mode
CALL IEEE_SET_ROUNDING_MODE(IEEE_UP) ! Resets the rounding mode
... CALL IEEE_SET_ROUNDING_MODE(VALUE) ! Restores the previous rounding mode
```

**IEEE_GET_STATUS**

*Intrinsic Module Subroutine (Generic): Stores the current state of the floating-point environment.*

**Module**

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS
```

**Syntax**

```fortran
CALL IEEE_GET_STATUS (status_value)
```

*status_value* (Input) Must be scalar and of type TYPE (IEEE_STATUS_TYPE). It stores the floating-point status. The result can only be used if IEEE_SET_STATUS is invoked.

**Example**

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC

TYPE(IEEE_STATUS_TYPE) STATUS

... CALL IEEE_GET_STATUS(STATUS) ! Stores the floating-point status
CALL IEEE_SET_FLAG(IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
... CALL IEEE_SET_STATUS(STATUS) ! Restores the floating-point status
```
**IEEE_GET_UNDERFLOW_MODE**

*Intrinsic Module Subroutine (Generic): Stores the current underflow mode.*

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_GET_UNDERFLOW_MODE (gradual)

gradual (Output) Must be default logical scalar.

The result is true if the current underflow mode is gradual (IEEE denormals are allowed) and false if the current underflow mode is abrupt (underflowed results are set to zero).

**Example**

Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS

LOGICAL GRAD

...

CALL IEEE_GET_UNDERFLOW_MODE(GRAD)

IF (GRAD) THEN ! underflows are gradual

...

ELSE ! underflows are abrupt

...

END IF

**IEEE_IS_FINITE**

*Elemental Module Intrinsic Function (Generic): Returns whether an IEEE value is finite.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC
Syntax

result = IEEE_ISFINITE (x)

x  
   (Input) Must be of type REAL.

Results

The result type is default logical. The result has the value true if the value of x is finite; otherwise, false.

An IEEE value is finite if IEEE_CLASS(x) has one of the following values:

<table>
<thead>
<tr>
<th>IEEE_POSITIVE_NORMAL</th>
<th>IEEE_NEGATIVE_DENORMAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_NEGATIVE_NORMAL</td>
<td>IEEE_POSITIVE_ZERO</td>
</tr>
<tr>
<td>IEEE_POSITIVE_DENORMAL</td>
<td>IEEE_NEGATIVE_ZERO</td>
</tr>
</tbody>
</table>

Example

IEEE_ISFINITE (-2.0) has the value true.

IEEE_IS_NAN

Elemental Module Intrinsic Function (Generic): Returns whether an IEEE value is Not-a-Number (NaN).

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_IS_NAN (x)

x  
   (Input) Must be of type REAL.

Results

The result type is default logical. The result has the value true if the value of x is NaN; otherwise, false.
Example
IEEE_IS_NAN (SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT (2.0) has the value true.

IEEE_IS_NEGATIVE
Elemental Module Intrinsic Function (Generic): Returns whether an IEEE value is negative.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_IS_NEGATIVE (x)

x (Input) Must be of type REAL.

Results
The result type is default logical. The result has the value true if the value of x is negative; otherwise, false.
An IEEE value is negative if IEEE_CLASS(x) has one of the following values:

| IEEE_NEGATIVE_NORMAL | IEEE_NEGATIVE_ZERO
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_NEGATIVE_DENORMAL</td>
<td>IEEE_NEGATIVE_INF</td>
</tr>
</tbody>
</table>

Example
IEEE_IS_NEGATIVE (2.0) has the value false.

IEEE_IS_NORMAL
Elemental Module Intrinsic Function (Generic): Returns whether an IEEE value is normal.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC
Syntax

\[
\text{result} = \text{IEEE\_IS\_NORMAL} \ (x)
\]

\[x\quad \text{(Input) Must be of type REAL.}\]

Results

The result type is default logical. The result has the value true if the value of \(x\) is normal; otherwise, false.

An IEEE value is normal if IEEE\_CLASS\(x\) has one of the following values:

<table>
<thead>
<tr>
<th>IEEE_POSITIVE_NORMAL</th>
<th>IEEE_POSITIVE_ZERO</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_NEGATIVE_NORMAL</td>
<td>IEEE_NEGATIVE_ZERO</td>
</tr>
</tbody>
</table>

Example

IEEE\_IS\_NORMAL (SQRT(-2.0)) has the value false if IEEE\_SUPPORT\_SQRT (-2.0) has the value true.

IEEE\_LOGB

**Elemental Module Intrinsic Function (Generic):** Returns a floating-point value equal to the unbiased exponent of the argument. This is equivalent to the IEEE logb function.

Module

\[
\text{USE, INTRINSIC :: IEEE\_ARITHMETIC}
\]

Syntax

\[
\text{result} = \text{IEEE\_LOGB} \ (x)
\]

\[x\quad \text{(Input) Must be of type REAL.}\]

Results

The result type is the same as \(x\). The result has the value of the unbiased exponent of \(x\) if the value of \(x\) is not zero, infinity, or NaN. The value of the result is equal to EXPONENT\(x\) - 1.

If \(x\) is equal to 0, the result is -infinity if IEEE\_SUPPORT\_INF\(x\) is true; otherwise, -HUGE\(x\). In either case, the IEEE\_DIVIDE\_BY\_ZERO exception is signaled.
Example

IEEE_LOGB (3.4) has the value 1.0; IEEE_LOGB (4.0) has the value 2.0.

IEEE_NEXT_AFTER

Elemental Module Intrinsic Function
(Generic): Returns the next representable value after X toward Y. This is equivalent to the IEEE nextafter function.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_NEXT_AFTER (x, y)

x (Input) Must be of type REAL.

y (Input) Must be of type REAL.

Results

The result type is the same as x. If x is equal to y, the result is x; no exception is signaled. If x is not equal to y, the result has the value of the next representable neighbor of x toward y. The neighbors of zero (of either sign) are both nonzero.

The following exceptions are signaled under certain cases:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Signalled</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_OVERFLOW</td>
<td>When X is finite but IEEE_NEXT_AFTER(X,Y) is infinite</td>
</tr>
<tr>
<td>IEEE_UNDERFLOW</td>
<td>When IEEE_NEXT_AFTER(X,Y) is denormalized</td>
</tr>
<tr>
<td>IEEE_INEXACT</td>
<td>In both the above cases</td>
</tr>
</tbody>
</table>

Example

The value of IEEE_NEXT_AFTER (2.0,3.0) is 2.0 + EPSILON (X).
IEEE_REM

Elemental Module Intrinsic Function (Generic): Returns the result value from a remainder operation. This is equivalent to the IEEE rem function.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_REM (x, y)

x (Input) Must be of type REAL.
y (Input) Must be of type REAL.

Results

The result type is real with the kind type parameter of whichever argument has greater precision. Regardless of the rounding mode, the result value is \( x - y \times N \), where \( N \) is the integer nearest to the value \( x / y \). If \( |N - x / y| = 1/2 \), \( N \) is even. If the result value is zero, the sign is the same as \( x \).

Example

The value of IEEE_REM (5.0, 4.0) is 1.0; the value of IEEE_REM (2.0, 1.0) is 0.0; the value of IEEE_REM (3.0, 2.0) is -1.0.

IEEE_RINT

Elemental Module Intrinsic Function (Generic): Returns an integer value rounded according to the current rounding mode.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_RINT (x)

x (Input) Must be of type REAL.
Results
The result type is the same as x. The value of the result is x rounded to an integer according to the current rounding mode. If the result value is zero, the sign is the same as x.

Example
If the current rounding mode is IEEE_UP, the value of IEEE_RINT (2.2) is 3.0.
If the current rounding mode is IEEE_NEAREST, the value of IEEE_RINT (2.2) is 2.0.

IEEE_SCALB
Elemental Module Intrinsic Function (Generic): Returns the exponent of a radix-independent floating-point number. This is equivalent to the IEEE scalb function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SCALB (x, i)

x (Input) Must be of type REAL.
i (Input) Must be of type INTEGER.

Results
The result type is the same as x. The result is x multiplied by 2**i, if the value can be represented as a normal number.
If x (2**i) is too small and there is a loss of accuracy, the exception IEEE_UNDERFLOW is signaled. The result value is the nearest number that can be represented with the same sign as x.
If x is finite and x (2**i) is too large, an IEEE_OVERFLOW exception occurs. If IEEE_SUPPORT_INF (x) is true, the result value is infinity with the same sign as x; otherwise, the result value is SIGN (HUGE(x), x).
If x is infinite, the result is the same as x; no exception is signaled.

Example
The value of IEEE_SCALB (2.0,3) is 16.0.
IEEE_SELECTED_REAL_KIND

Transformational Module Intrinsic Function (Generic): Returns the value of the kind parameter of an IEEE REAL data type.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SELECTED_REAL_KIND (p), r)

p (Input; optional) Must be scalar and of type INTEGER.

r (Input; optional) Must be scalar and of type INTEGER.

At least one argument must be specified.

Results

The result is a scalar of type default integer. The result has a value equal to a value of the kind parameter of an IEEE real data type with decimal precision, as returned by the function PRECISION, of at least p digits and a decimal exponent range, as returned by the function RANGE, of at least r.

If no such kind type parameter is available on the processor, the result is as follows:

-1 if the precision is not available
-2 if the exponent range is not available
-3 if neither the precision nor the exponent range is available
-4 if one but not both of the precision and the exponent range is available.

If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision.

Example

IEEE_SELECTED_REAL_KIND (6, 70) = 8.

- H to I
- Model for Real Data
**IEEE_SET_FLAG**
*Elemental Module Intrinsic Function (Generic): Assigns a value to an exception flag.*

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_SET_FLAG (flag, flag_value)

*flag*  
(Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:  
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

*flag_value*  
(Output) Must be of type default logical. If it has the value true, the exception in 'flag' is set to signal; otherwise, the exception is set to be quiet.

**Example**

Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use module IEEE_ARITHMETIC

...  
CALL IEEE_SET_FLAG (IEEE_INVALID, .TRUE.) ! Sets the IEEE_INVALID flag to signal

**IEEE_SET_HALTING_MODE**
*Elemental Module Intrinsic Function (Generic): Controls halting or continuation after an exception.*

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_SET_HALTING_MODE (flag, halting)
flag (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags: IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

halting (Input) Must be scalar and of type default logical. If the value is true, the exception specified in FLAG will cause halting; otherwise, execution will continue after this exception.

Example
Consider the following:
USE, INTRINSIC :: IEEE_EXCEPTIONS

LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT) ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT) ! Restores halting

IEEE_SET_ROUNDING_MODE
Intrinsic Module Subroutine (Generic): Sets the IEEE rounding mode.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
CALL IEEE_SET_ROUNDING_MODE (round_value)

round_value (Output) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It specifies one of the following IEEE floating-point rounding values: IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, IEEE_UP, or IEEE_OTHER.
Example

Consider the following:

```
USE, INTRINSIC :: IEEE_ARITHMETIC

TYPE (IEEE_ROUND_TYPE) ROUND
...
CALL IEEE_GET_ROUNDING_MODE (ROUND) ! Stores the rounding mode
CALL IEEE_SET_ROUNDING_MODE (IEEE_UP) ! Resets the rounding mode
...
CALL IEEE_SET_ROUNDING_MODE (VALUE) ! Restores the previous rounding mode
```

**IEEE_SET_STATUS**

*Intrinsic Module Subroutine (Generic):*

*Restores the state of the floating-point environment.*

**Module**

```
USE, INTRINSIC :: IEEE_EXCEPTIONS
```

**Syntax**

```
CALL IEEE_SET_STATUS (status_value)
```

*status_value* (Input) Must be scalar and of type TYPE (IEEE_STATUS_TYPE). Its value must be set in a previous invocation of IEEE_GET_STATUS.
Example

Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC
TYPE (IEEE_STATUS_TYPE) STATUS
...
CALL IEEE_GET_STATUS (STATUS) ! Stores the floating-point status
CALL IEEE_SET_FLAG (IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
...
CALL IEEE_SET_STATUS (STATUS) ! Restores the floating-point status

IEEE_SET_UNDERFLOW_MODE

_Intrinsic Module Subroutine (Generic): Sets the current underflow mode._

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

CALL IEEE_SET_UNDERFLOW_MODE (gradual)

(gradual) (Input) Must be scalar and of type default logical. If it is true, the current underflow mode is set to gradual underflow (denormals may be produced on underflow). If it is false, the current underflow mode is set to abrupt (underflowed results are set to zero).

Example

Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL :: SG

... CALL IEEE_GET_UNDERFLOW_MODE (SG) ! Stores underflow mode
CALL IEEE_SET_UNDERFLOW_MODE (.FALSE.) ! Resets underflow mode

... ! Abrupt underflows happens here
CALL IEEE_SET_UNDERFLOW_MODE (SG) ! Restores previous underflow mode

**IEEE_SUPPORT_DATATYPE**

Inquiry Module Intrinsic Function (Generic):

Returns whether the processor supports IEEE arithmetic.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_SUPPORT_DATATYPE ([x])
```

x

(Input; optional) Must be scalar and of type REAL.

**Results**

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports IEEE arithmetic for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports IEEE arithmetic for real variables of the same kind type parameter as x; otherwise, false.

If real values are implemented according to the IEEE standard except that underflowed values flush to zero (abrupt) instead of being denormal.

**Example**

IEEE_SUPPORT_DATATYPE (3.0) has the value true.
IEEE_SUPPORT_DENORMAL

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE denormalized numbers.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SUPPORT_DENORMAL ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports arithmetic operations and assignments with denormalized numbers for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports arithmetic operations and assignments with denormalized numbers for real variables of the same kind type parameter as x; otherwise, false.

Example

IEEE_SUPPORT_DENORMAL () has the value true if IEEE denormalized numbers are supported for all real types.

IEEE_SUPPORT_DIVIDE

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE divide.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SUPPORT_DIVIDE ([x])
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_DIVIDE ( ) has the value true if IEEE divide is supported for all real types.

IEEE_SUPPORT_FLAG

Inquiry Module Intrinsic Function (Generic):

Returns whether the processor supports IEEE exceptions.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
result = IEEE_SUPPORT_FLAG (flag [, x])

flag (Input) Must be a scalar of type TYPE (IEEE_FLAG_TYPE). Its value is one of the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
IEEE_OVERFLOW, or IEEE_UNDERFLOW.

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports detection of the exception specified by "flag" for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports detection of the exception specified by "flag" for real variables of the same kind type parameter as x; otherwise, false.

Example

IEEE_SUPPORT_FLAG (IEEE_UNDERFLOW) has the value true if the IEEE_UNDERFLOW exception is supported for all real types.

**IEEE_SUPPORT_HALTING**

*Inquiry Module Intrinsic Function (Generic):*

*Returns whether the processor supports IEEE halting.*

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

result = IEEE_SUPPORT_HALTING(flag)

flag (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:

IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

**Results**

The result is a scalar of type default logical. The result has the value true if the processor supports the ability to control halting after the exception specified by "flag"; otherwise, false.

Example

IEEE_SUPPORT_HALTING (IEEE_UNDERFLOW) has the value true if halting is supported after an IEEE_UNDERFLOW exception

**IEEE_SUPPORT_INF**

*Inquiry Module Intrinsic Function (Generic):*

*Returns whether the processor supports IEEE infinities.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC
Syntax

\[ \text{result} = \text{IEEE\_SUPPORT\_INF} \left( \{x\} \right) \]

\( x \)  
(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If \( x \) is omitted, the result has the value true if the processor supports IEEE infinities (positive and negative) for all real values; otherwise, false.

If \( x \) is specified, the result has the value true if the processor supports IEEE infinities for real variables of the same kind type parameter as \( x \); otherwise, false.

Example

\( \text{IEEE\_SUPPORT\_INF}( ) \) has the value true if IEEE infinities are supported for all real types.

**IEEE\_SUPPORT\_IO**

*Inquiry Module Intrinsic Function (Generic):*

*Returns whether the processor supports IEEE base conversion rounding during formatted I/O.*

Module

USE, INTRINSIC :: IEEE\_ARITHMETIC

Syntax

\[ \text{result} = \text{IEEE\_SUPPORT\_IO} \left( \{x\} \right) \]

\( x \)  
(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If \( x \) is omitted, the result has the value true if the processor supports base conversion rounding during formatted input and output for all real values; otherwise, false.

If \( x \) is specified, the result has the value true if the processor supports base conversion rounding during formatted input and output for real variables of the same kind type parameter as \( x \); otherwise, false.
The base conversion rounding applies to modes IEEE_UP, IEEE_DOWN, IEEE_TO_ZERO, and IEEE_NEAR.

Example
IEEE_SUPPORT_IO () has the value true if base conversion rounding is supported for all real types during formatted I/O.

IEEE_SUPPORT_NAN
Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE Not-a-Number feature.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_NAN ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports NaNs for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports NaNs for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_NAN () has the value true if IEEE NaNs are supported for all real types.

IEEE_SUPPORT_ROUNDING
Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE rounding mode.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC
Syntax

result = IEEE_SUPPORT_ROUNDING (round_value [, x])

round_value (Input) Must be of type TYPE(IEEE_ROUND_TYPE). It specifies one of the following rounding modes: IEEE_UP, IEEE_DOWN, IEEE_TO_ZERO, and IEEE_NEAREST.

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports the rounding mode specified by round_value for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports the rounding mode specified by round_value for real variables of the same kind type parameter as x; otherwise, false.

Example

IEEE_SUPPORT_ROUNDING (IEEE_DOWN) has the value true if rounding mode IEEE_DOWN is supported for all real types.

IEEE_SUPPORT_SQRT

Inquiry Module Intrinsic Function (Generic): Returns whether the processor supports IEEE SQRT (square root).

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SUPPORT_SQRT (x)

x (Input; optional) Must be of type REAL; it can be scalar or array valued.
Results

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor implements SQRT in accord with the IEEE standard for all real values; otherwise, false.

If x is specified, the result has the value true if the processor implements SQRT in accord with the IEEE standard for real variables of the same kind type parameter as x; otherwise, false.

Example

IEEE_SUPPORT_SQRT ( ) has the value true if IEEE SQRT is supported for all real types.

**IEEE_SUPPORT_STANDARD**

*Inquiry Module Intrinsic Function (Generic):*

Returns whether the processor supports IEEE features defined in the standard.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_SUPPORT_STANDARD ( [x] )
```

`x` (Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. The result has the value true if the results of all the following functions are true (x can be omitted):

- IEEE_SUPPORT_DATATYPE([x])
- IEEE_SUPPORT_DENORMAL([x])
- IEEE_SUPPORT_DIVIDE([x])
- IEEE_SUPPORT_FLAG(flag [, x])
- IEEE_SUPPORT_HALTING(flag)
- IEEE_SUPPORT_INF([x])

2858
IEEE_SUPPORT_NAN([x])
IEEE_SUPPORT_ROUNDING(round_value [, x])²
IEEE_SUPPORT_SQRT([x])

1: "flag" must be a valid value
2: "round_value" must be a valid value
Otherwise, the result has the value, false.

Example
IEEE_SUPPORT_STANDARD () has the value false if both IEEE and non-IEEE real kinds are supported.

IEEE_SUPPORT_UNDERFLOW_CONTROL

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports the ability to control the underflow mode.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_UNDERFLOW_CONTROL ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports controlling the underflow mode for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports controlling the underflow mode for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_UNDERFLOW_CONTROL () has the value true if controlling the underflow mode is supported for all real types.
IEEE_UNORDERED

Elemental Module Intrinsic Function (Generic): Returns whether one or more of the arguments is Not-a-Number (NaN). This is equivalent to the IEEE unordered function.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_UNORDERED (x, y)

x  (Input) Must be of type REAL.
y  (Input) Must be of type REAL.

Results

The result type is default logical. The result has the value true if x or y is a NaN, or both are NaNs; otherwise, false.

Example

IEEE_UNORDERED (0.0, SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT (2.0) has the value true.

IEEE_VALUE

Elemental Module Intrinsic Function (Generic): Creates an IEEE value.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_VALUE (x, class)

x  (Input) Must be of type REAL.
class (Input) Must be of type TYPE (IEEE_CLASS_TYPE). Its value is one of the following:
Results
The result type is the same as x. The result value is an IEEE value as specified by "class".
When IEEE_VALUE returns a signaling NaN, it is processor dependent whether or not invalid is signaled and processor dependent whether or not the signaling NaN is converted to a quiet NaN.

Example
IEEE_VALUE (1.0, IEEE_POSITIVE_INF) has the value +infinity.

IEEE_FLAGS
Portability Function: Gets, sets or clears IEEE flags for rounding direction and precision as well as queries or controls exception status. This function provides easy access to the modes and status required to use the features of IEEE Standard 754-1985 arithmetic in a Fortran program.

Module
USE IFPORT

Syntax
result = IEEE_FLAGS (action, mode, in, out)

action (Input) Character*(*) . One of the following literal values: 'GET', 'SET', 'CLEAR', or 'CLEARALL'.

<table>
<thead>
<tr>
<th>IEEE_SIGNALING_NAN</th>
<th>IEEE_NEGATIVE_NORMAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_QUITE_NAN</td>
<td>IEEE_POSITIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_POSITIVE_INF</td>
<td>IEEE_NEGATIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_NEGATIVE_INF</td>
<td>IEEE_POSITIVE_ZERO</td>
</tr>
<tr>
<td>IEEE_POSITIVE_NORMAL</td>
<td>IEEE_NEGATIVE_ZERO</td>
</tr>
</tbody>
</table>
**mode**

(Input) Character*(*)

- One of the following literal values: 'direction', 'precision', or 'exception'. The value 'precision' is only allowed on Intel® 64 architecture and IA-32 architecture.

**in**

(Input) Character*(*)

- One of the following literal values: 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', 'common', 'nearest', 'tozero', 'negative', 'positive', 'extended', 'double', 'single', or ' ', which represents an unused (null) value.

**out**

(Output) Must be at least CHARACTER*9

- One of the literal values listed for **in**.

The descriptions for the values allowed for **in** and **out** can be summarized as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'nearest'</td>
<td>Rounding direction flags</td>
</tr>
<tr>
<td>'tozero'</td>
<td></td>
</tr>
<tr>
<td>'negative'</td>
<td></td>
</tr>
<tr>
<td>'positive'</td>
<td></td>
</tr>
<tr>
<td>'single'</td>
<td>Rounding precision flags</td>
</tr>
<tr>
<td>'double'</td>
<td></td>
</tr>
<tr>
<td>'extended'</td>
<td></td>
</tr>
<tr>
<td>'inexact'</td>
<td>Math exception flags</td>
</tr>
<tr>
<td>'underflow'</td>
<td></td>
</tr>
<tr>
<td>'overflow'</td>
<td></td>
</tr>
<tr>
<td>'division'</td>
<td></td>
</tr>
<tr>
<td>'invalid'</td>
<td></td>
</tr>
<tr>
<td>'all'</td>
<td>All math exception flags above</td>
</tr>
<tr>
<td>'common'</td>
<td>The math exception flags: 'invalid', 'division', 'overflow', and 'underflow'</td>
</tr>
</tbody>
</table>
The values for \( \text{in} \) and \( \text{out} \) depend on the \textit{action} and \textit{mode} they are used with. The interaction of the parameters can be summarized as follows:

<table>
<thead>
<tr>
<th>Value of action</th>
<th>Value of mode</th>
<th>Value of in</th>
<th>Value of out</th>
<th>Functionality and return value</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>'direction'</td>
<td>Null (' ')</td>
<td>One of 'nearest', 'tozero', 'negative', or 'positive'</td>
<td>Tests rounding direction settings. Returns the current setting, or 'not available'.</td>
</tr>
<tr>
<td>'exception'</td>
<td>Null (' ')</td>
<td>One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'</td>
<td>Tests math exception settings. Returns the current setting, or 0.</td>
<td></td>
</tr>
<tr>
<td>'precision'</td>
<td>Null (' ')</td>
<td>One of 'single', 'double', or 'extended'</td>
<td>Tests rounding precision settings. Returns the current setting, or 'not available'.</td>
<td></td>
</tr>
<tr>
<td>Value of action</td>
<td>Value of mode</td>
<td>Value of in</td>
<td>Value of out</td>
<td>Functionality and return value</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------</td>
<td>-------------</td>
<td>--------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>SET</td>
<td>'direction'</td>
<td>One of 'nearest', 'tozero', 'negative', or 'positive'</td>
<td>Null (' ')</td>
<td>Sets a rounding direction.</td>
</tr>
<tr>
<td>'exception'</td>
<td>One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'</td>
<td>Null (' ')</td>
<td>Sets a floating-point math exception.</td>
<td></td>
</tr>
<tr>
<td>'precision'</td>
<td>One of 'single', 'double', or 'extended'</td>
<td>Null (' ')</td>
<td>Sets a rounding precision.</td>
<td></td>
</tr>
<tr>
<td>CLEAR</td>
<td>'direction'</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Clears the mode. Sets rounding to 'nearest'. Returns 0 if successful.</td>
</tr>
<tr>
<td>'exception'</td>
<td>One of 'inexact', 'division',</td>
<td>Null (' ')</td>
<td>Clears the mode.</td>
<td></td>
</tr>
<tr>
<td>Value of action</td>
<td>Value of mode</td>
<td>Value of in</td>
<td>Value of out</td>
<td>Functionality and return value</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------</td>
<td>-------------</td>
<td>--------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>'underflow', 'overflow', 'invalid', 'all', or 'common'</td>
<td></td>
<td></td>
<td></td>
<td>Returns 0 if successful.</td>
</tr>
<tr>
<td>'precision'</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td></td>
<td>Clears the mode. Sets precision to 'double' (W<em>32, W</em>64) or 'extended' (L<em>X, M</em>X). Returns 0 if successful.</td>
</tr>
<tr>
<td>CLEARALL</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Null (' ')</td>
<td>Clears all flags. Sets rounding to 'nearest', sets precision to 'double' (W<em>32, W</em>64) or 'extended' (L<em>X, M</em>X), and sets all exception flags to 0.</td>
</tr>
</tbody>
</table>
IEEE_FLAGS is an elemental, integer-valued function that sets IEEE flags for GET, SET, CLEAR, or CLEARALL procedures. It lets you control rounding direction and rounding precision, query exception status, and control exception enabling or disabling by using the SET or CLEAR procedures, respectively.

The flags information is returned as a set of 1-bit flags.

**Example**

The following example gets the highest priority exception that has a flag raised. It passes the input argument *in* as a null string:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*9 out
iflag = ieee_flags('get', 'exception', '', out)
PRINT *, out, ' flag raised'
```

The following example sets the rounding direction to round toward zero, unless the hardware does not support directed rounding modes:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('set', 'direction', 'tozero', out)
```
The following example sets the rounding direction to the default ('nearest'):
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out, in
iflag = ieee_flags('clear','direction', '', '' )

The following example clears all exceptions:
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out
iflag = ieee_flags('clear','exception', 'all', '' )

The following example restores default direction and precision settings, and sets all exception flags to 0:
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('clearall', '', '', '')

The following example detects an underflow exception:
USE IFPORT
CHARACTER*20 out, in
excep_detect = ieee_flags('get', 'exception', 'underflow', out)
if (out .eq.'underflow') stop 'underflow'

IEEE_HANDLER

Portability Function: Establishes a handler for IEEE exceptions.

Module
USE IFPORT

Syntax
result = IEEE_HANDLER (action, exception, handler)
**action**
(Input) Character*(*)
One of the following literal IEEE actions: 'GET', 'SET', or 'CLEAR'.
For more details on these actions, see IEEE_FLAGS.

**exception**
(Input) Character*(*)
One of the following literal IEEE exception flags: 'inexact', 'underflow', 'overflow', 'division', 'invalid', 'all'
(which equals the previous five flags), or 'common' (which equals 'invalid', 'overflow', 'underflow', and 'division').
The flags 'all' or 'common' should only be used for actions SET or CLEAR.

**handler**
(Input) The address of an external signal-handling routine.

**Results**
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture.
The result is 0 if successful; otherwise, 1.

IEEE_HANDLER calls a signal-handling routine to establish a handler for IEEE exceptions. It also enables an FPU trap corresponding to the required exception.

The state of the FPU is not defined in the handler routine. When the FPU trap occurs, the program invokes the handler routine. After the handler routine is executed, the program terminates.

The handler routine gets the exception code in the SIGINFO argument. SIGNO is the number of the system signal. The meaning of the SIGINFO constants appears in the following table (defined in the IFPORT module):

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPE$INVALID</td>
<td>Invalid operation</td>
</tr>
<tr>
<td>FPE$ZERODIVIDE</td>
<td>Divide-by-zero</td>
</tr>
<tr>
<td>FPE$OVERFLOW</td>
<td>Numeric overflow</td>
</tr>
<tr>
<td>FPE$UNDERFLOW</td>
<td>Numeric underflow</td>
</tr>
<tr>
<td>FPE$INEXACT</td>
<td>Inexact result (precision)</td>
</tr>
</tbody>
</table>

'GET' actions return the location of the current handler routine for exception cast to an INTEGER.
Example

The following example creates a handler routine and sets it to trap divide-by-zero:

```fortran
PROGRAM TEST_IEEE
  REAL :: X, Y, Z
  CALL FPE_SETUP
  X = 0.
  Y = 1.
  Z = Y / X
END PROGRAM

SUBROUTINE FPE_SETUP
  USE IFPORT
  IMPLICIT NONE

  INTERFACE
    SUBROUTINE FPE_HANDLER(SIGNO, SIGINFO)
      INTEGER(4), INTENT(IN) :: SIGNO, SIGINFO
    END SUBROUTINE
  END INTERFACE

  INTEGER IR
  IR = IEEE_HANDLER('set','division',FPE_HANDLER)
END SUBROUTINE FPE_SETUP

SUBROUTINE FPE_HANDLER(SIG, CODE)
  USE IFPORT
  IMPLICIT NONE

  INTEGER SIG, CODE
  IF(CODE.EQ.FPE$ZERODIVIDE) PRINT *, 'Occurred divide by zero.'
  CALL ABORT
END SUBROUTINE FPE_HANDLER
```

• H to I
• IEEE_FLAGS

IEOR
Elemental Intrinsic Function (Generic):
Performs an exclusive OR on corresponding bits.
This function can also be specified as XOR or IXOR.

Syntax
result = IEOR (i, j)

i  (Input) Must be of type integer or of type logical (which is treated as an integer).

j  (Input) Must be of type integer with the same kind parameter as i. If the kinds of i and j do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

Results
The result type is the same as i. The result value is derived by combining i and j bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>i</th>
<th>j</th>
<th>IEOR (i, j)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIEOR&lt;sup&gt;1&lt;/sup&gt;</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIEOR&lt;sup&gt;2&lt;/sup&gt;</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JIEOR&lt;sup&gt;3&lt;/sup&gt;</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>Specific Name</td>
<td>Argument Type</td>
<td>Result Type</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>KIEOR</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

1. Or BIXOR
2. Or HIEOR, HIXOR, or IIXOR
3. Or JIXOR

**Example**
IEOR (12, 7) has the value 11; binary 1100 exclusive OR with binary 0111 is binary 1011.

The following shows another example:
```fortran
INTEGER I
I = IEOR(240, 90) ! returns 170
   ! IEOR ('11110000', '1011010') == '10101010'
```

The following shows an example using alternate option XOR:
```fortran
INTEGER i, j, k
i = 3       ! B'011'
j = 5       ! B'101'
k = XOR(i, j) ! returns 6 = B'110'
```

**See Also**
- H to I
- IAND
- IOR
- NOT

**IERRNO**

*Portability Function:* Returns the number of the last detected error from any routines in the IFPORT module that return error codes.

**Module**

USE IFPORT
Syntax

result = IERRNO( )

Results

The result type is INTEGER(4). The result value is the last error code from any portability routines that return error codes. These error codes are analogous to errno on a Linux* or Mac OS* X system. The module IFPORT.F90 provides parameter definitions for the following errno names (typically found in errno.h on Linux systems):

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>1</td>
<td>Insufficient permission for operation</td>
</tr>
<tr>
<td>ENOENT</td>
<td>2</td>
<td>No such file or directory</td>
</tr>
<tr>
<td>ESRCH</td>
<td>3</td>
<td>No such process</td>
</tr>
<tr>
<td>EIO</td>
<td>5</td>

</tbody>
</table>

The value returned by IERRNO is updated only when an error occurs. For example, if an error occurs on a GETLOG call and then two CHMOD calls succeed, a subsequent call to IERRNO returns the error for the GETLOG call.

Examine IERRNO immediately after returning from a portability routine. Other Fortran routines, as well as any Windows* APIs, can also change the error code to an undefined value. IERRNO is set on a per thread basis.
**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFPORT

CHARACTER*20 username

INTEGER(4) ierrval

ierrval=0 !initialize return value

CALL GETLOG(username)

IF (IERRNO( ) == ierrval) then
    print *, 'User name is ',username
    exit

ELSE
    ierrval = ierrno()
    print *, 'Error is ',ierrval

END IF

**IF - Arithmetic**

*Statement:* Conditionally transfers control to one of three statements, based on the value of an arithmetic expression. It is an obsolescent feature in Fortran 95 and Fortran 90.

**Syntax**

IF (expr) label1,label2,label3

*expr* is a scalar numeric expression of type integer or real (enclosed in parentheses).

*label1, label2, label3* are the labels of valid branch target statements that are in the same scoping unit as the arithmetic IF statement.

**Description**

All three labels are required, but they do not need to refer to three different statements. The same label can appear more than once in the same arithmetic IF statement.
During execution, the expression is evaluated first. Depending on the value of the expression, control is then transferred as follows:

<table>
<thead>
<tr>
<th>If the Value of expr is:</th>
<th>Control Transfers To:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 0</td>
<td>Statement label1</td>
</tr>
<tr>
<td>Equal to 0</td>
<td>Statement label2</td>
</tr>
<tr>
<td>Greater than 0</td>
<td>Statement label3</td>
</tr>
</tbody>
</table>

**Example**

The following example transfers control to statement 50 if the real variable THETA is less than or equal to the real variable CHI. Control passes to statement 100 only if THETA is greater than CHI.

\[
\text{IF (THETA - CHI) 50,50,100}
\]

The following example transfers control to statement 40 if the value of the integer variable NUMBER is even. It transfers control to statement 20 if the value is odd.

\[
\text{IF (NUMBER / 2 * 2 - NUMBER) 20,40,20}
\]

The following statement transfers control to statement 10 for \(n < 10\), to statement 20 for \(n = 10\), and to statement 30 for \(n > 10\): 

\[
\text{IF (n-10) 10, 20, 30}
\]

The following statement transfers control to statement 10 if \(n \leq 10\), and to statement 30 for \(n > 10\): 

\[
\text{IF (n-10) 10, 10, 30}
\]

**See Also**

- H to I
- SELECT CASE...END SELECT
- Execution Control
- Obsolescent Features in Fortran 90
**IF - Logical**

**Statement:** Conditionally executes one statement based on the value of a logical expression. (This statement was called a logical IF statement in FORTRAN 77.)

**Syntax**

```
IF (expr) stmt
```

- **expr** Is a scalar logical expression enclosed in parentheses.
- **stmt** Is any complete, unlabeled, executable Fortran statement, except for the following:
  - A CASE, DO, IF, FORALL, or WHERE construct
  - Another IF statement
  - The END statement for a program, function, or subroutine

When an IF statement is executed, the logical expression is evaluated first. If the value is true, the statement is executed. If the value is false, the statement is not executed and control transfers to the next statement in the program.

**Example**

The following examples show valid IF statements:

```
IF (J.GT.4 .OR. J.LT.1) GO TO 250
IF (REF(J,K) .NE. HOLD) REF(J,K) = REF(J,K) * (-1.5D0)
IF (ENDRUN) CALL EXIT
```
The following shows another example:

```
USE IFPORT

INTEGER(4) istat, errget
character(inchar)
real x
iset = getc(inchar)
IF (iset) errget = -1
...
! IF (x .GT. 2.3) call new_subr(x)
...
```

See Also

- H to I
- IF Construct
- Execution Control

**IF Construct**

*Statement:* Conditionally executes one block of constructs or statements depending on the evaluation of a logical expression. (This construct was called a block IF statement in FORTRAN 77.)

**Syntax**

```
name: IF (expr) THEN
block
[ELSE IF (expr) THEN [name]
block]
[ELSE [name]
block]
END IF [name]
```

- *name:* (Optional) Is the name of the IF construct.
- *expr:* Is a scalar logical expression enclosed in parentheses.
block

Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of an IF THEN statement, the same name must appear in the corresponding END IF statement. The same construct name must not be used for different named constructs in the same scoping unit.

Depending on the evaluation of the logical expression, one block or no block is executed. The logical expressions are evaluated in the order in which they appear, until a true value is found or an ELSE or END IF statement is encountered.

Once a true value is found or an ELSE statement is encountered, the block immediately following it is executed and the construct execution terminates.

If none of the logical expressions evaluate to true and no ELSE statement appears in the construct, no block in the construct is executed and the construct execution terminates.

NOTE. No additional statement can be placed after the IF THEN statement in a block IF construct. For example, the following statement is invalid in the block IF construct:

\[
\text{IF (e) THEN I = J}
\]

This statement is translated as the following logical IF statement:

\[
\text{IF (e) THEN I = J}
\]

You cannot use branching statements to transfer control to an ELSE IF statement or ELSE statement. However, you can branch to an END IF statement from within the IF construct.
The following figure shows the flow of control in IF constructs:
Figure 62: Flow of Control in IF Constructs
You can include an IF construct in the statement block of another IF construct, if the nested IF construct is completely contained within a statement block. It cannot overlap statement blocks.

**Example**

The following example shows the simplest form of an IF construct:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN block</td>
<td>IF (ABS(ADJU) .GE. 1.0E-6) THEN</td>
</tr>
<tr>
<td>block block</td>
<td>block block</td>
</tr>
<tr>
<td>TOTERR = TOTERR + ABS(ADJU)</td>
<td>QUEST = ADJU/FNDVAL</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

This construct conditionally executes the block of statements between the IF THEN and the END IF statements.

The following shows another example:

! Simple block IF:

```
IF (i .LT. 10) THEN
   ! the next two statements are only executed if i < 10
   j = i
   slice = TAN (angle)
END IF
```

The following example shows a named IF construct:

```
BLOCK_A: IF (D > 0.0) THEN ! Initial statement for named construct
   RADIANS = ACOS(D) ! These two statements
   DEGREES = ACOSD(D) ! form a block
END IF BLOCK_A ! Terminal statement for named construct
```
The following example shows an IF construct containing an ELSE statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (NAME .LT. 'N') THEN</td>
</tr>
<tr>
<td>block1</td>
<td>IFront = IFRONT + 1</td>
</tr>
<tr>
<td></td>
<td>Fllet(IFRONT) = NAME(1:2)</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block2</td>
<td>Iback = IBACK + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

Block1 consists of all the statements between the IF THEN and ELSE statements. Block2 consists of all the statements between the ELSE and the END IF statements.

If the value of the character variable NAME is less than 'N', block1 is executed. If the value of NAME is greater than or equal to 'N', block2 is executed.

The following example shows an IF construct containing an ELSE IF THEN statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>block1</td>
<td>IF (A .GT. B) THEN</td>
</tr>
<tr>
<td></td>
<td>D = B</td>
</tr>
<tr>
<td></td>
<td>F = A - B</td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. B/2.) THEN</td>
</tr>
<tr>
<td>block2</td>
<td>D = B/2.</td>
</tr>
<tr>
<td></td>
<td>F = A - B/2.</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

If A is greater than B, block1 is executed. If A is not greater than B, but A is greater than B/2, block2 is executed. If A is not greater than B and A is not greater than B/2, neither block1 nor block2 is executed. Control transfers directly to the next executable statement after the END IF statement.
The following shows another example:

! Block IF with ELSE IF statements:

IF (j .GT. 1000) THEN
    ! Statements here are executed only if J > 1000
ELSE IF (j .GT. 100) THEN
    ! Statements here are executed only if J > 100 and j <= 1000
ELSE IF (j .GT. 10) THEN
    ! Statements here are executed only if J > 10 and j <= 100
ELSE
    ! Statements here are executed only if j <= 10
END IF

The following example shows an IF construct containing several ELSE IF THEN statements and an ELSE statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .GT. B) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>D = B</td>
</tr>
<tr>
<td></td>
<td>F = A - B</td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. C) THEN</td>
</tr>
<tr>
<td>block2</td>
<td>D = C</td>
</tr>
<tr>
<td></td>
<td>F = A - C</td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. Z) THEN</td>
</tr>
<tr>
<td>block3</td>
<td>D = Z</td>
</tr>
<tr>
<td></td>
<td>F = A - Z</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block4</td>
<td>D = 0.0</td>
</tr>
<tr>
<td></td>
<td>F = A</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>
If A is greater than B, block1 is executed. If A is not greater than B but is greater than C, block2 is executed. If A is not greater than B or C but is greater than Z, block3 is executed. If A is not greater than B, C, or Z, block4 is executed.

The following example shows a nested IF construct:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .LT. 100) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>INRAN = INRAN + 1</td>
</tr>
<tr>
<td>IF (expr2) THEN</td>
<td>IF (ABS(A-AVG) .LE. 5.) THEN</td>
</tr>
<tr>
<td>block1a</td>
<td>INAVG = INAVG + 1</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block1b</td>
<td>OUTAVG = OUTAVG + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block2</td>
<td>OUTRAN = OUTRAN + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

If A is less than 100, the code immediately following the IF is executed. This code contains a nested IF construct. If the absolute value of A minus AVG is less than or equal to 5, block1a is executed. If the absolute value of A minus AVG is greater than 5, block1b is executed.

If A is greater than or equal to 100, block2 is executed, and the nested IF construct (in block1) is not executed.
The following shows another example:

```fortran
! Nesting of constructs and use of an ELSE statement following
! a block IF without intervening ELSE IF statements:
IF (i .LT. 100) THEN
  ! Statements here executed only if i < 100
  IF (j .LT. 10) THEN
    ! Statements here executed only if i < 100 and j < 10
    END IF
  ! Statements here executed only if i < 100
ELSE
  ! Statements here executed only if i >= 100
  IF (j .LT. 10) THEN
    ! Statements here executed only if i >= 100 and j < 10
    END IF
  ! Statements here executed only if i >= 100
END IF
```

**IF Directive Construct**

**General Compiler Directive**: A conditional compilation construct that begins with an IF or IF DEFINED directive. IF tests whether a logical expression is .TRUE. or .FALSE.. IF DEFINED tests whether a symbol has been defined.

**Syntax**

```
cDEC$ IF (expr) -or- cDEC$ IF DEFINED (name)
```
block
[cDEC$ ELSEIF (expr)
  block] ...
[cDEC$ ELSE
  block]
cDEC$ ENDF

c
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

expr
Is a logical expression that evaluates to .TRUE. or .FALSE..

name
Is the name of a symbol to be tested for definition.

block
Are executable statements that are compiled (or not) depending on the value of logical expressions in the IF directive construct.

The IF and IF DEFINED directive constructs end with an ENDF directive and can contain one or more ELSEIF directives and at most one ELSE directive. If the logical condition within a directive evaluates to .TRUE. at compilation, and all preceding conditions in the IF construct evaluate to .FALSE., then the statements contained in the directive block are compiled.

A name can be defined with a DEFINE directive, and can optionally be assigned an integer value. If the symbol has been defined, with or without being assigned a value, IF DEFINED (name) evaluates to .TRUE.; otherwise, it evaluates to .FALSE..

If the logical condition in the IF or IF DEFINED directive is .TRUE., statements within the IF or IF DEFINED block are compiled. If the condition is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.

If the logical expression in an ELSEIF directive is .TRUE., statements within the ELSEIF block are compiled. If the expression is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.

If control reaches an ELSE directive because all previous logical conditions in the IF construct evaluated to .FALSE., the statements in an ELSE block are compiled unconditionally.

You can use any Fortran logical or relational operator or symbol in the logical expression of the directive, including: .LT., <, .GT., >, .EQ., ==, .LE., <=, .GE., >=, .NE., /=, .EQV., .NEQV., .NOT., .AND., .OR., and .XOR.. The logical expression can be as complex as you like, but the whole directive must fit on one line.
Example

! When the following code is compiled and run,
! the output is:
! Or this compiled if all preceding conditions .FALSE.
!
!DEC$ DEFINE flag=3
!DEC$ IF (flag .LT. 2)
   WRITE (*,*) "This is compiled if flag less than 2."
!DEC$ ELSEIF (flag >= 8)
   WRITE (*,*) "Or this compiled if flag greater than &
or equal to 8."
!DEC$ ELSE
   WRITE (*,*) "Or this compiled if all preceding &
   conditions .FALSE." 
!DEC$ ENDIF
END

**IFIX**

*Elemental Intrinsic Function (Generic):*

Converts a single-precision real argument to an integer by truncating. See *INT*.

---

**IFLOATI, IFLOATJ**

*Portability Functions:* Convert an integer to single-precision real type.

---

**Module**

USE IFPORT

---

**Syntax**

result = IFLOATI (i)

result = IFLOATJ (j)

---

**Input**

- i (Input) Must be of type INTEGER(2).
- j (Input) Must be of type INTEGER(4).

---

**Results**

The result type is single-precision real (REAL(4) or REAL*4).

---

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

---

**See Also**

- H to I
- DFLOAT
**ILEN**

*Inquiry Intrinsic Function (Generic):* Returns the length (in bits) of the two's complement representation of an integer.

**Syntax**

```fortran
result = ILEN (i)
```

*i* Must be of type integer.

**Results**

The result type is the same as *i*. The result value is \((\log_2 (i + 1))\) if *i* is not negative; otherwise, the result value is \((\log_2 (-i))\).

**Example**

ILEN (4) has the value 3.
ILEN (-4) has the value 2.

**IMAGESIZE, IMAGESIZE_W (W*32, W*64)**

*Graphics Functions:* Return the number of bytes needed to store the image inside the specified bounding rectangle. IMAGESIZE is useful for determining how much memory is needed for a call to GETIMAGE.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = IMAGESIZE (x1,y1,x2,y2)
result = IMAGESIZE_W (wx1,wy1,wx2,wy2)
```

*x1, y1* (Input) INTEGER(2). Viewport coordinates for upper-left corner of image.

*x2, y2* (Input) INTEGER(2). Viewport coordinates for lower-right corner of image.
**IMPLICIT**

**Statement:** Overrides the default implicit typing rules for names. (The default data type is INTEGER for names beginning with the letters I through N, and REAL for names beginning with any other letter.)

**Syntax**

The IMPLICIT statement takes one of the following forms:

```
IMPLICIT type(a[,a]...)[,type(a[,a]...)]...
```
IMPLICIT NONE

type = Is a data type specifier (CHARACTER*(*) is not allowed).
a = Is a single letter, a dollar sign ($), or a range of letters in alphabetical order. The form for a range of letters is a₁-a₂, where the second letter follows the first alphabetically (for example, A-C).

The dollar sign can be used at the end of a range of letters, since IMPLICIT interprets the dollar sign to alphabetically follow the letter Z. For example, a range of X-$ would apply to identifiers beginning with the letters X, Y, Z, or $.

In Intel® Fortran, the parentheses around the list of letters are optional.

Description

The IMPLICIT statement assigns the specified data type (and kind parameter) to all names that have no explicit data type and begin with the specified letter or range of letters. It has no effect on the default types of intrinsic procedures.

When the data type is CHARACTER*len, len is the length for character type. The len is an unsigned integer constant or an integer specification expression enclosed in parentheses. The range for len is 1 to 2**31-1 on IA-32 architecture; 1 to 2**63-1 on Intel® 64 architecture and IA-64 architecture.

Names beginning with a dollar sign ($) are implicitly INTEGER.

The IMPLICIT NONE statement disables all implicit typing defaults. When IMPLICIT NONE is used, all names in a program unit must be explicitly declared. An IMPLICIT NONE statement must precede any PARAMETER statements, and there must be no other IMPLICIT statements in the scoping unit.

NOTE. To receive diagnostic messages when variables are used but not declared, you can specify compiler option warn declarations instead of using IMPLICIT NONE.

The following IMPLICIT statement represents the default typing as specified by the Fortran Standard for names when they are not explicitly typed:

IMPLICIT INTEGER (I-N), REAL (A-H, O-Z)

Example

The following are examples of the IMPLICIT statement:

IMPLICIT DOUBLE PRECISION (D) IMPLICIT COMPLEX (S,Y), LOGICAL(1) (L,A-C)
IMPLICIT CHARACTER*32 (T-V)

IMPLICIT CHARACTER*2 (W)

IMPLICIT TYPE(COLORS) (E-F), INTEGER (G-H)

The following shows another example:

SUBROUTINE FF (J)

IMPLICIT INTEGER (a-b), CHARACTER*(J+1) (n), TYPE(fried) (c-d)

TYPE fried

INTEGER e, f

REAL g, h

END TYPE

age = 10 ! integer

name = 'Paul' ! character

c%e = 1 ! type fried, integer component

• H to I
• Data Types, Constants, and Variables
• warn declarations compiler option

IMPORT

Statement: Makes host entities accessible in the interface body of an interface block. It takes the following form:

Syntax

IMPORT [[::] import-name-list]
**import-name-list**  
(Input) Is the name of one or more entities in the host scoping unit.

An IMPORT statement can appear only in an interface body. Each of the named entities must be explicitly declared before the interface body containing the IMPORT statement.

If **import-name-list** is not specified, all of the accessible named entities in the host scoping unit are imported.

The default is that all accessible symbols are imported. This statement can optionally name only those symbols you choose.

The names of imported entities must not appear in any context that causes the host entity to be inaccessible.

**Example**
The following example shows how the IMPORT statement can be applied.

```fortran
module mymod
  type mytype
    integer comp
  end type mytype
  interface
    subroutine sub (arg)
      import
      type(mytype) :: arg
    end subroutine sub
  end interface
end module mymod
```

**INCHARQ** ([W*32, W*64])

*QuickWin Function:* Reads a single character input from the keyboard and returns the ASCII value of that character without any buffering.

**Module**

```fortran
USE IFQWIN
```
Syntax

result = INCHARQQ( )

Results

The result type is INTEGER(2). The result is the ASCII key code.

The keystroke is read from the child window that currently has the focus. You must call INCHARQQ before the keystroke is made (INCHARQQ does not read the keyboard buffer). This function does not echo its input. For function keys, INCHARQQ returns 0xE0 as the upper 8 bits, and the ASCII code as the lower 8 bits.

For direction keys, INCHARQQ returns 0xF0 as the upper 8 bits, and the ASCII code as the lower 8 bits. To allow direction keys to be read, you must use the PASSDIRKEYSQQ function. The escape characters (the upper 8 bits) are different from those of GETCHARQQ. Note that console applications do not need, and cannot use PASSDIRKEYSQQ.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

use IFQWIN

integer*4 res
integer*2 exchar
character*1 ch, ch1

Print *, "Type X to exit, S to scroll, D to pass Direction keys"
123 continue

exchar = incharqq()

! check for escapes
!
!
!

ch = char(rshift(exchar,8) .and. Z'00FF')
ch1 = char(exchar .and. Z'00FF')

if (ichar(ch) .eq. 224) then

print *, "function key = ", ichar(ch), ",", ichar(ch1), ",", ch1

goto 123
endif

if (ichar(ch) .eq. 240) then

print *, "direction key = ", ichar(ch), ",", ichar(ch1), ",", ch1

goto 123
endif

print *, "other key = ", ichar(ch), ",", ichar(ch1), ",", ch1

if(ch1 .eq. 'S') then

res = passdirkeysqq(.false.)

print *, "Entering Scroll mode"
endif

if(ch1 .eq. 'D') then

res = passdirkeysqq(.true.)
print *, "Entering Direction keys mode"
endif
if(ch1 .ne. 'X') go to 123
end

Building Applications: Using QuickWin Overview
Building Applications: Blocking Procedures

INCLUDE

Statement: Directs the compiler to stop reading statements from the current file and read statements in an included file or text module.

Syntax
The INCLUDE line takes the following form:

INCLUDE 'filename[/NO]LIST'

filename Is a character string specifying the name of the file to be included; it must not be a named constant.
The form of the file name must be acceptable to the operating system, as described in your system documentation.

[NO]LIST Specifies whether the incorporated code is to appear in the compilation source listing. In the listing, a number precedes each incorporated statement. The number indicates the "include" nesting depth of the code. The default is /NOLIST. /LIST and /NOLIST must be spelled completely.
You can only use /[NO]LIST if you specify compiler option vms (which sets OpenVMS defaults).
Description

An INCLUDE line can appear anywhere within a scoping unit. The line can span more than one source line, but no other statement can appear on the same line. The source line cannot be labeled.

An included file or text module cannot begin with a continuation line, and each Fortran statement must be completely contained within a single file.

An included file or text module can contain any source text, but it cannot begin or end with an incomplete Fortran statement.

The included statements, when combined with the other statements in the compilation, must satisfy the statement-ordering restrictions shown in Statements.

Included files or text modules can contain additional INCLUDE lines, but they must not be recursive. INCLUDE lines can be nested until system resources are exhausted.

When the included file or text module completes execution, compilation resumes with the statement following the INCLUDE line.

You can use modules instead of include files to achieve encapsulation of related data types and procedures. For example, one module can contain derived type definitions as well as special operators and procedures that apply to those types. For information on how to use modules, see Program Units and Procedures.
Example
In the following example, a file named COMMON.FOR (in the current working directory) is included and read as input.

Figure 63: Including Text from a File

<table>
<thead>
<tr>
<th>Main Program File</th>
<th>COMMON.FOR File</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROGRAM</td>
<td></td>
</tr>
<tr>
<td>INCLUDE 'COMMON.FOR'</td>
<td>INTEGER, PARAMETER :: M=100</td>
</tr>
<tr>
<td>REAL, DIMENSION(M) :: Z</td>
<td>REAL, DIMENSION(M) :: X, Y</td>
</tr>
<tr>
<td>CALL CUBE</td>
<td>COMMON X, Y</td>
</tr>
<tr>
<td>DO I = 1, M</td>
<td></td>
</tr>
<tr>
<td>Z(I) = X(I) + SQRT(Y(I))</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>END DO</td>
<td></td>
</tr>
<tr>
<td>END</td>
<td></td>
</tr>
</tbody>
</table>

SUBROUTINE CUBE

INCLUDE 'COMMON.FOR'

DO I=1,M
  X(I) = Y(I)**3
END DO
RETURN
END

The file COMMON.FOR defines a named constant M, and defines arrays X and Y as part of blank common.

The following example program declares its common data in an include file. The contents of the file INCLUDE.INC are inserted in the source code in place of every INCLUDE 'INCLUDE.INC' line. This guarantees that all references to common storage variables are consistent.

INTEGER i
REAL x
INCLUDE 'INCLUDE.INC'
DO i = 1, 5
  READ (*, '(F10.5)') x
  CALL Push (x)
END DO

• H to I
• MODULE
• USE

INDEX

Elemental Intrinsic Function (Generic):
Returns the starting position of a substring within a string.

Syntax
result = INDEX (string, substring [,back] [, kind])
  string        (Input) Must be of type character.
  substring     (Input) Must be of type character.
  back          (Input; optional) Must be of type logical.
  kind          (Input; optional) Must be a scalar integer initialization expression.

Results
The result is of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If back does not appear (or appears with the value false), the value returned is the minimum value of I such that string(I : I + LEN (substring) - 1) = substring (or zero if there is no such value). If LEN (string) < LEN (substring), zero is returned. If LEN (substring) = zero, 1 is returned.
If back appears with the value true, the value returned is the maximum value of I such that
string(I : I + LEN(substring) - 1) = substring (or zero if there is no such value). If
LEN(string) < LEN(substring), zero is returned. If LEN(substring) = zero, LEN(string) + 1 is returned.

The setting of compiler options specifying integer size can affect this function.

Example
INDEX ('FORTRAN', 'O', BACK = .TRUE.) has the value 2.
INDEX ('XXXX', ' ', BACK = .TRUE.) has the value 5.

The following shows another example:
I = INDEX('banana','an', BACK = .TRUE.) ! returns 4
I = INDEX('banana', 'an') ! returns 2

INITIALIZEFONTS (W*32, W*64)

Module
USE IFQWIN

Syntax
result = INITIALIZEFONTS( )
Results

The result type is INTEGER(2). The result is the number of fonts initialized.

All fonts on Windows systems become available after a call to INITIALIZEFONTS. Fonts must be initialized with INITIALIZEFONTS before any other font-related library function (such as GETFONTINFO, GETGTEXTEXTENT, SETFONT, OUTGTEXT) can be used. For more information, see Building Applications: Using Fonts from the Graphics Library.

The font functions affect the output of OUTGTEXT only. They do not affect other Fortran I/O functions (such as WRITE) or graphics output functions (such as OUTTEXT).

For each window you open, you must call INITIALIZEFONTS before calling SETFONT. INITIALIZEFONTS needs to be executed after each new child window is opened in order for a subsequent SETFONT call to be successful.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example

! build as a QuickWin or Standard Graphics App.

USE IFQWIN

INTEGER(2) numfonts

numfonts = INITIALIZEFONTS()

WRITE (*,*) numfonts

END

See Also

- H to I
- SETFONT
- OUTGTEXT

Building Applications: Initializing Fonts

INITIALSETTINGS (W*32, W*64)

QuickWin Function: Initializes QuickWin.

Module

USE IFQWIN
Syntax

result = INITIALSETTINGS( )

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can change the initial appearance of an application's default frame window and menus by defining an INITIALSETTINGS function. Do not use INITIALSETTINGS to open or size child windows.

If no user-defined INITIALSETTINGS function is supplied, QuickWin calls a predefined INITIALSETTINGS routine to control the default frame window and menu appearance. You do not need to call INITIALSETTINGS if you define it, since it will be called automatically during initialization.

For more information, see Building Applications: Controlling the Initial Menu and Frame Window.

Compatibility

QUICKWIN GRAPHICS WINDOWS LIB

INMAX

Portability Function: Returns the maximum positive value for an integer.

Module

USE IFPORT

Syntax

result = INMAX (i)
Results
The result type is INTEGER(4). The result is the maximum 4-byte signed integer value for the argument.

**INQFOCUSQQ (W*32, W*64)**

*QuickWin Function: Determines which window has the focus.*

**Module**
USE IFQWIN

**Syntax**

```
result = INQFOCUSQQ (unit)
```

*unit* (Output) INTEGER(4). Unit number of the window that has the I/O focus.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero. The function fails if the window with the focus is associated with a closed unit.

Unit numbers 0, 5, and 6 refer to the default window only if the program has not specifically opened them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

The window with focus is always in the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.

A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when an I/O statement is executed on that unit. For example:

```
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```
By default IOFOCUS=.TRUE., except for child windows opened with as unit *. If
IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or
OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to
shift.

Building Applications: Using QuickWin Overview

INQUIRE

**Statement:** Returns information on the status of
specified properties of a file, logical unit, or
directory. It takes one of the following forms:

**Syntax**

**Inquiring by File:**

INQUIRE (FILE=name [, ERR=label] [, IOSTAT=i-var] [, DEFAULTFILE=def] slist)

**Inquiring by Unit:**

INQUIRE ([UNIT]=io-unit [, ERR=label] [, IOSTAT=i-var] slist)

**Inquiring by Directory:**

INQUIRE (DIRECTORY=dir, EXIST=ex [, DIRSPEC=dirspec] [, ERR=label] [, IOSTAT=i-var])

**Inquiring by Output List:**

INQUIRE (IOLENGTH=len) out-item-list

*name* Is a scalar default character expression specifying the name of the
file for inquiry. For more information, see FILE Specifier and
STATUS Specifier.

*label* Is the label of the branch target statement that receives control
if an error occurs. For more information, see Branch Specifiers.
**i-var**

Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs. For more information, see I/O Status Specifier.

**def**

Is a scalar default character expression specifying a default file pathname string. (For more information, see the DEFAULTFILE specifier.)

**slist**

Is one or more of the following inquiry specifiers (each specifier can appear only once):

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS</td>
<td>DELIM</td>
</tr>
<tr>
<td>ACTION</td>
<td>DIRECT</td>
</tr>
<tr>
<td>ASYNCHRONOUS</td>
<td>EXIST</td>
</tr>
<tr>
<td>BINARY</td>
<td>FORM</td>
</tr>
<tr>
<td>BLANK</td>
<td>FORMATTED</td>
</tr>
<tr>
<td>BLOCKSIZE</td>
<td>ID</td>
</tr>
<tr>
<td>BUFFERED</td>
<td>IOFOCUS</td>
</tr>
<tr>
<td>CARRIAGECONTROL</td>
<td>MODE</td>
</tr>
<tr>
<td>CONVERT</td>
<td>NAME</td>
</tr>
<tr>
<td>IO-UNIT</td>
<td>NAME</td>
</tr>
<tr>
<td>IO-UNIT</td>
<td>POSITION</td>
</tr>
</tbody>
</table>

**io-unit**

Is an external unit specifier. The unit does not have to exist, nor does it need to be connected to a file. If the unit is connected to a file, the inquiry encompasses both the connection and the file.

**dir**

Is a scalar default character expression specifying the name of the directory for inquiry. If you are inquiring by directory, it must be present.

**ex**

Is a scalar default logical variable that is assigned the value .TRUE. if *dir* names a directory that exists; otherwise, *ex* is assigned the value .FALSE.. If you are inquiring by directory, it must be present. For more information, see the EXIST Specifier.
**dirspec**
Is a scalar default character variable that is assigned the value of the full directory specification of `dir` if `ex` is assigned the value .TRUE.. This specifier can only be used when inquiring by directory.

**len**
(Output) Is a scalar integer variable that is assigned a value corresponding to the length of an unformatted, direct-access record resulting from the use of the `out-item-list` in a WRITE statement. The value is suitable to use as a RECL specifier value in an OPEN statement that connects a file for unformatted, direct access. The unit of the value is 4-byte longwords, by default. However, if you specify compiler option assume byterecl, the unit is bytes.

**out-item-list**
(Output) Is a list of one or more output items (see I/O Lists).

**Description**
The control specifiers ([UNIT=] `io-unit`, `ERR= label`, and `IOSTAT=` `i-var`) and inquiry specifiers can appear anywhere within the parentheses following INQUIRE. However, if the UNIT keyword is omitted, the `io-unit` must appear first in the list.

An INQUIRE statement can be executed before, during, or after a file is connected to a unit. The specifier values returned are those that are current when the INQUIRE statement executes.

To get file characteristics, specify the INQUIRE statement after opening the file.

**Example**
The following are examples of INQUIRE statements:

```
INQUIRE (FILE='FILE_B', EXIST=EXT)
INQUIRE (4, FORM=FM, IOSTAT=IOS, ERR=20)
INQUIRE (IOLENGTH=LEN) A, B
```

In the last statement, you can use the length returned in LEN as the value for the RECL specifier in an OPEN statement that connects a file for unformatted direct access. If you have already specified a value for RECL, you can check LEN to verify that A and B are less than or equal to the record length you specified.
The following shows another example:

```fortran
! This program prompts for the name of a data file.
! The INQUIRE statement then determines whether
! the file exists. If it does not, the program
! prompts for another file name.
CHARACTER*12 fname
LOGICAL exists
! Get the name of a file:
100 WRITE (*, '(1X, A)') 'Enter the file name:
READ (*, '(A)') fname
! INQUIRE about file's existence:
INQUIRE (FILE = fname, EXIST = exists)
IF (.NOT. exists) THEN
    WRITE (*,'(A/)') ' >> Cannot find file ', fname
    GOTO 100
END IF
END
```

**INSERTMENUQQ (W*32, W*64)**

*QuickWin Function:* Inserts a menu item into a QuickWin menu and registers its callback routine.

**Module**

USE IFQWIN

**Syntax**

```
result = INSERTMENUQQ (menuID, itemID, flag, text, routine)
```

- **menuID** (Input) INTEGER(4). Identifies the menu in which the item is inserted, starting with 1 as the leftmost menu.
- **itemID** (Input) INTEGER(4). Identifies the position in the menu where the item is inserted, starting with 0 as the top menu item.
- **flag** (Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see Results section below). The following constants are available:
  - $MENUGRAYED - Disables and grays out the menu item.
  - $MENUDISABLED - Disables but does not gray out the menu item.
  - $MENUSEPARATOR - Draws a separator bar.
  - $MENUCHECKED - Puts a check by the menu item.
  - $MENUUNCHECKED - Removes the check by the menu item.
- **text** (Input) Character*(*)*. Menu item name. Must be a null-terminated C string, for example, words of text 'C.'
- **routine** (Input) EXERNAL. Callback subroutine that is called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:
  - WINPRINT - Prints the program.
  - WINSAVE - Saves the program.
  - WINEXIT - Terminates the program.
• WINSELECTTEXT - Selects text from the current window.
• WINSELECTGRAPHICS - Selects graphics from the current window.
• WINSELECTALL - Selects the entire contents of the current window.
• WININPUT - Brings to the top the child window requesting input and makes it the current window.
• WINCOPY - Copies the selected text and/or graphics from current window to the Clipboard.
• WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
• WINCLEARPASTE - Clears the paste buffer.
• WINSIZETO FIT - Sizes output to fit window.
• WINFULLSCREEN - Displays output in full screen.
• WINSTATE - Toggles between pause and resume states of text output.
• WINCASCADE - Cascades active windows.
• WINTILE - Tiles active windows.
• WINARRANGE - Arranges icons.
• WINSTATUS - Enables a status bar.
• WININDEX - Displays the index for QuickWin help.
• WINUSING - Displays information on how to use Help.
• WINABOUT - Displays information about the current QuickWin application.
• NUL - No callback routine.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE.
Menus and menu items must be defined in order from left to right and top to bottom. For example, INSERTMENUQQ fails if you try to insert menu item 7 when 5 and 6 are not defined yet. For a top-level menu item, the callback routine is ignored if there are subitems under it.
The constants available for flags can be combined with an inclusive OR where reasonable, for example $MENUCHECKED .OR. $MENUNABLED. Some combinations do not make sense, such as $MENUNABLED and $MENUDISABLED, and lead to undefined behavior.

You can create quick-access keys in the text strings you pass to INSERTMENUQQ as text by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, text should be "P&rint". Quick-access keys allow users of your program to activate that menu item with the key combination ALT+QUICK-ACCESS-KEY(ALT+R in the example) as an alternative to selecting the item with the mouse.

For more information on customizing QuickWin menus, see Building Applications: Using QuickWin Overview.

**Compatibility**

QUICKWIN GRAPHICS LIB

**Example**

! build as a QuickWin App.
USE IFQWIN
LOGICAL(4) status
! insert new item into Menu 5 (Window)
status= INSERTMENUQQ(5, 5, $MENUCHECKED, 'New Item'C, 
   WINSTATUS)
! insert new menu in position 2
status= INSERTMENUQQ(2, 0, $MENUNABLED, 'New Menu'C, 
   WINSAVE)
END

**INT**

*Elemental Intrinsic Function (Generic):*  
Converts a value to integer type.

**Syntax**

\[
\text{result} = \text{INT}(a[,\text{kind}])
\]

- \(a\) (Input) Must be of type integer, real, or complex.
- \(\text{kind}\) (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is integer. If \(\text{kind}\) is present, the kind parameter of the result is that specified by \(\text{kind}\); otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

Functions that cause conversion of one data type to another type have the same affect as the implied conversion in assignment statements.

The result value depends on the type and absolute value of \(a\), as follows:

- If \(a\) is of type integer, \(\text{INT}(a) = a\).
- If \(a\) is of type real and \(|a| < 1\), \(\text{INT}(a)\) has the value zero.
  
  If \(a\) is of type real and \(|a| >= 1\), \(\text{INT}(a)\) is the integer whose magnitude is the largest integer that does not exceed the magnitude of \(a\) and whose sign is the same as the sign of \(a\).

- If \(a\) is of type complex, \(\text{INT}(a) = a\) is the value obtained by applying the preceding rules (for a real argument) to the real part of \(a\).

</tbody>
</table>

<sup>1</sup>These specific functions cannot be passed as actual arguments.

<sup>2</sup>This function can also be specified as HFIX.
The setting of compiler options specifying integer size or real size can affect IFIX.

For compatibility with older versions of Fortran, IFIX is treated as a generic function.

Or JINT.

The setting of compiler options specifying integer size can affect INT, IDINT, and IQINT.

Or JIFIX.

Or JIDINT. For compatibility with older versions of Fortran, IDINT can also be specified as a generic function.

Or JIQINT. For compatibility with older versions of Fortran, IQINT can also be specified as a generic function.

For compatibility, these functions can also be specified as generic functions.

Example

INT (-4.2) has the value -4.

INT (7.8) has the value 7.

INTC

Portability Function: Converts an INTEGER(4) argument to INTEGER(2) type.

Module

USE IFPORT
Syntax
\[ \text{result} = \text{INTC}(i) \]

\( i \) \hspace{1cm} \text{(Input) INTEGER(4). A value or expression.}

Results
The result type is INTEGER(2). The result is the value of \( i \) with type INTEGER(2). Overflow is ignored.

\textbf{INT_PTR_KIND}

\textit{Inquiry Intrinsic Function (Specific):} Returns the INTEGER KIND that will hold an address. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax
\[ \text{result} = \text{INT_PTR_KIND}() \]

Results
The result type is default integer. The result is a scalar with the value equal to the value of the kind parameter of the integer data type that can represent an address on the host platform.

The result value is 4 on IA-32 architecture; 8 on Intel\textsuperscript{®} 64 architecture and IA-64 architecture.

Example
\begin{verbatim}
  REAL A(100)
  POINTER (P, A)
  INTEGER (KIND=INT_PTR_KIND()) SAVE_P
  P = MALLOC (400)
  SAVE_P = P
\end{verbatim}
**INTEGER Statement**

**Statement:** Specifies the INTEGER data type.

**Syntax**

INTEGER

INTEGER([KIND=] \(n\))

INTEGER*\(n\)

\(n\) is kind 1, 2, 4, or 8.

If a kind parameter is specified, the integer has the kind specified. If a kind parameter is not specified, integer constants are interpreted as follows:

- If the integer constant is within the default integer kind range, the kind is default integer.
- If the integer constant is outside the default integer kind range, the kind of the integer constant is the smallest integer kind which holds the constant.

The default kind can also be changed by using the INTEGER directive or compiler options specifying integer size.

**Example**

! Entity-oriented declarations:

INTEGER, DIMENSION(:), POINTER :: days, hours

INTEGER (2) :: k=4

INTEGER (2), PARAMETER :: limit=12

! Attribute-oriented declarations:

INTEGER days, hours

INTEGER (2):: k=4, limit

DIMENSION days(:), hours(:)

POINTER days, hours

PARAMETER (limit=12)

**See Also**

- H to I
• INTEGER Directive
• Integer Data Types
• Integer Constants

**INTEGER Directive**

*General Compiler Directive: Specifies the default integer kind.*

**Syntax**

```
c DEC$ INTEGER: { 2 | 4 | 8 }
```

- `c` is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

The INTEGER directive specifies a size of 2 (KIND=2), 4 (KIND=4), or 8 (KIND=8) bytes for default integer numbers.

When the INTEGER directive is in effect, all default integer variables are of the kind specified. Only numbers specified or implied as INTEGER without KIND are affected.

The INTEGER directive can only appear at the top of a program unit. A program unit is a main program, an external subroutine or function, a module or a block data program unit. INTEGER cannot appear between program units, or at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.

The default logical kind is the same as the default integer kind. So, when you change the default integer kind you also change the default logical kind.
Example

INTEGER i ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2( )
WRITE(*,*) KIND(i) ! still a 4-byte integer
! not affected by setting in subroutine
END

SUBROUTINE INTEGER2( )
!DEC$ INTEGER:2
INTEGER j ! a 2-byte integer
WRITE(*,*) KIND(j)
END SUBROUTINE

INTEGERTORGB (W*32, W*64)

QuickWin Subroutine: Converts an RGB color value into its red, green, and blue components.

Module
USE IFQWIN

Syntax
CALL INTEGERTORGB (rgb, red, green, blue)

rgb (Input) INTEGER(4). RGB color value whose red, green, and blue components are to be returned.
red        (Output) INTEGER(4). Intensity of the red component of the RGB color value.
green     (Output) INTEGER(4). Intensity of the green component of the RGB color value.
blue      (Output) INTEGER(4). Intensity of the blue component of the RGB color value.

INTEGRERTORGB separates the four-byte RGB color value into the three components as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0 B B B B B B G G G G G G R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Compatibility**
QUICKWIN GRAPHICS WINDOWS LIB

**Example**
! build as a QuickWin App.
USE IFQWIN
INTEGER(4) r, g, b
CALL INTEGRERTORGB(2456, r, g, b)
write(*,*) r, g, b
END

- GETBKCOLORRRGB
- GETPIXELRRGB
- GETPIXELSRGB
- GETTEXTCOLORRRGB

*Building Applications: Using QuickWin Overview*
**INTENT**

**Statement and Attribute:** Specifies the intended use of one or more dummy arguments.

**Syntax**

The INTENT attribute can be specified in a type declaration statement or an INTENT statement, and takes one of the following forms:

**Type Declaration Statement:**

\[\text{type}, [\text{att-}\text{ls}], \text{INTENT } (\text{intent-spec}) [, \text{att-}\text{ls}] :: \text{d-arg}[, \text{d-arg}]\ldots\]

**Statement:**

\[\text{INTENT } (\text{intent-spec}) [::]\text{d-arg}[, \text{d-arg}]\ldots\]

- **type** Is a data type specifier.
- **att-\text{ls}** Is an optional list of attribute specifiers.
- **intent-spec** Is one of the following specifiers:
  - **IN** Specifies that the dummy argument will be used only to provide data to the procedure. The dummy argument must not be redefined (or become undefined) during execution of the procedure.
  - **OUT** Specifies that the dummy argument will be used to pass data from the procedure back to the calling program. The dummy argument is undefined on entry and must be defined before it is referenced in the procedure. Any associated actual argument must be definable.
  - **INOUT** Specifies that the dummy argument can both provide data to the procedure and return data to the calling program. Any associated actual argument must be definable.
- **d-arg** Is the name of a dummy argument or dummy pointer. It cannot be a dummy procedure.
**Description**

The INTENT statement can only appear in the specification part of a subprogram or interface body.

If no INTENT attribute is specified for a dummy argument, its use is subject to the limitations of the associated actual argument.

If a function specifies a defined operator, the dummy arguments must have intent IN.

If a subroutine specifies defined assignment, the first argument must have intent OUT or INOUT, and the second argument must have intent IN.

A non-pointer dummy argument with intent IN (or a subobject of such a dummy argument) must not appear as any of the following:

- A DO variable
- The variable of an assignment statement
- The pointer-object of a pointer assignment statement
- An object or STAT variable in an ALLOCATE or DEALLOCATE statement
- An input item in a READ statement
- A variable name in a NAMELIST statement if the namelist group name appears in a NML specifier in a READ statement
- An internal file unit in a WRITE statement
- A definable variable in an INQUIRE statement
- An IOSTAT or SIZE specifier in an I/O statement
- An actual argument in a reference to a procedure with an explicit interface if the associated dummy argument has intent OUT or INOUT

INTENT on a pointer dummy argument refers to the pointer association status of the pointer and has no effect on the value of the target of the pointer.

A pointer dummy argument with intent IN (or a subobject of such a pointer argument) must not appear as any of the following:

- A pointer-object in a NULLIFY statement
- A pointer-object in a pointer assignment statement
- An object in an ALLOCATE or DEALLOCATE statement
• An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the \texttt{INTENT(OUT)} or \texttt{INTENT(INOUT)} attribute.

If an actual argument is an array section with a vector subscript, it cannot be associated with a dummy array that is defined or redefined (has intent \texttt{OUT} or \texttt{INOUT}).

\textbf{Example}

The following example shows type declaration statements specifying the \texttt{INTENT} attribute:

\begin{verbatim}
SUBROUTINE TEST(I, J)
    INTEGER, INTENT(IN) :: I
    INTEGER, INTENT(OUT), DIMENSION(I) :: J
\end{verbatim}

The following are examples of the \texttt{INTENT} statement:

\begin{verbatim}
SUBROUTINE TEST(A, B, X)
    INTENT(INOUT) :: A, B
    ...
SUBROUTINE CHANGE(FROM, TO)
    USE EMPLOYEE_MODULE
    TYPE(EMPLOYEE) FROM, TO
    INTENT(IN) FROM
    INTENT(OUT) TO
    ...
\end{verbatim}
The following shows another example:

```fortran
SUBROUTINE AVERAGE(value, data1, cube_ave)
  TYPE DATA
    INTEGER count
    REAL avg
  END TYPE
  TYPE(DATA) data1
  REAL tmp
  ! value cannot be changed, while cube_ave must be defined
  ! before it can be used. Data1 is defined when the procedure is
  ! invoked, and becomes redefined in the subroutine.
  INTENT(IN)::value; INTENT(OUT)::cube_ave
  INTENT(INOUT)::data1
  ! count number of times AVERAGE has been called on the data set
  ! being passed.
  tmp = data1%count*data1%avg + value
  data1%count = data1%count + 1
  data1%avg = tmp/data1%count
  cube_ave = data1%avg**3
END SUBROUTINE
```

**INTERFACE**

**Statement:** Defines explicit interfaces for external or dummy procedures. It can also be used to define a generic name for procedures, a new operator for functions, and a new form of assignment for subroutines.

**Syntax**

`INTERFACE [generic-spec]

[interface-body]...

[MODULE PROCEDURE name-list]...

END INTERFACE [generic-spec]`

`generic-spec` (Optional) Is one of the following:

- A generic name
  For information on generic names, see *Program Units and Procedures.*
- `OPERATOR ( op)`
  Defines a generic operator (`op`). It can be a defined unary, defined binary, or extended intrinsic operator. For information on defined operators, see *Program Units and Procedures.*
- `ASSIGNMENT (=)`
  Defines generic assignment. For information on defined assignment, see *Assignment - Defined Assignment.*

`interface-body` Is one or more function or subroutine subprograms. A function must end with `END FUNCTION` and a subroutine must end with `END SUBROUTINE`. The subprogram must *not* contain a `statement function` or a `DATA`, `ENTRY`, or `FORMAT` statement; an entry name can be used as a procedure name. The subprogram can contain a `USE` statement.
name-list

Is the name of one or more module procedures that are accessible in the host. The **MODULE PROCEDURE** statement is only allowed if the interface block specifies a *generic-spec* and has a host that is a module (or accesses a module by use association). The characteristics of module procedures are not given in interface blocks, but are assumed from the module subprogram definitions.

**Description**

Interface blocks can appear in the specification part of the program unit that invokes the external or dummy procedure.

A *generic-spec* can only appear in the **END INTERFACE** statement (a Fortran 95 feature) if one appears in the **INTERFACE** statement; they must be identical.

The characteristics specified for the external or dummy procedure must be consistent with those specified in the procedure's definition.

An interface block must not appear in a block data program unit.

An interface block comprises its own scoping unit, and does not inherit anything from its host through host association.

Internal, module, and intrinsic procedures are all considered to have explicit interfaces. External procedures have implicit interfaces by default; when you specify an interface block for them, their interface becomes explicit. A procedure must not have more than one explicit interface in a given scoping unit. This means that you cannot include internal, module, or intrinsic procedures in an interface block, unless you want to define a generic name for them.

A interface block containing *generic-spec* specifies a generic interface for the following procedures:

- The procedures within the interface block
  
  Any generic name, defined operator, or equals symbol that appears is a generic identifier for all the procedures in the interface block. For the rules on how any two procedures with the same generic identifier must differ, see **Unambiguous Generic Procedure References**.

- The module procedures listed in the **MODULE PROCEDURE** statement
  
  The module procedures must be accessible by a **USE** statement.

To make an interface block available to multiple program units (through a **USE** statement), place the interface block in a module.

The following rules apply to interface blocks containing pure procedures:
• The interface specification of a pure procedure must declare the INTENT of all dummy arguments except pointer and procedure arguments.

• A procedure that is declared pure in its definition can also be declared pure in an interface block. However, if it is not declared pure in its definition, it must not be declared pure in an interface block.

**Example**

The following example shows a simple procedure interface block with no generic specification:

```f77
SUBROUTINE SUB_B (B, FB)
   REAL B ...
INTERFACE
   FUNCTION FB (GN)
      REAL FB, GN
   END FUNCTION
END INTERFACE
```

The following shows another example:

```f77
!An interface to an external subroutine SUB1 with header:
!SUBROUTINE SUB1(I1,I2,R1,R2)
!INTEGER I1,I2
!REAL R1,R2
INTERFACE
   SUBROUTINE SUB1(int1,int2,real1,real2)
      INTEGER int1,int2
      REAL real1,real2
   END SUBROUTINE SUB1
END INTERFACE
```

INTEGER int

...

INTERFACE TO

**Statement:** Identifies a subprogram and its actual arguments before it is referenced or called.

**Syntax**

```fortran
INTERFACE TO subprogram-stmt
    [formal-declarations]
END
```

- `subprogram-stmt` is a function or subroutine declaration statement.
- `formal-declarations` (Optional) Are type declaration statements (including optional attributes) for the arguments.

The INTERFACE TO block defines an explicit interface, but it contains specifications for only the procedure declared in the INTERFACE TO statement. The explicit interface is defined only in the program unit that contains the INTERFACE TO statement.

The recommended method for defining explicit interfaces is to use an INTERFACE block.

**Example**

Consider that a C function that has the following prototype:

```c
extern void Foo (int i);
```
The following INTERFACE TO block declares the Fortran call to this function:

```fortran
INTERFACE TO SUBROUTINE Foo [C.ALIAS: '_Foo'] (I)

   INTEGER*4 I

END
```

See Also

- H to I
- INTERFACE

INTRINSIC

**Statement and Attribute:** Allows the specific name of an intrinsic procedure to be used as an actual argument.

**Syntax**

The INTRINSIC attribute can be specified in a type declaration statement or an INTRINSIC statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
type,[att-ls] INTRINSIC [, att-ls] :: in-pro[, in-pro]...
```

**Statement:**

```fortran
INTRINSIC [:] in-pro[, in-pro] ...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `in-pro` Is the name of an intrinsic procedure.

**Description**

In a type declaration statement, only *functions* can be declared INTRINSIC. However, you can use the INTRINSIC statement to declare subroutines, as well as functions, to be intrinsic.

The name declared INTRINSIC is assumed to be the name of an intrinsic procedure. If a generic intrinsic function name is given the INTRINSIC attribute, the name retains its generic properties.

Some specific intrinsic function names cannot be used as actual arguments. For more information, see Intrinsic Functions Not Allowed as Actual Arguments.
Example

The following example shows a type declaration statement specifying the INTRINSIC attribute:

```
PROGRAM EXAMPLE
...
REAL(8), INTRINSIC :: DACOS
...
CALL TEST(X, DACOS) ! Intrinsic function DACOS is an actual argument
```

The following example shows an INTRINSIC statement:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERNAL CTN</td>
<td>SUBROUTINE TRIG(X,F,Y)</td>
</tr>
<tr>
<td>INTRINSIC SIN, COS</td>
<td>Y = F(X)</td>
</tr>
<tr>
<td>...</td>
<td>RETURN</td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE,SIN,SINE)</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td>FUNCTION CTN(X)</td>
</tr>
<tr>
<td></td>
<td>CTN = COS(X)/SIN(X)</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE,COS,COSINE)</td>
<td>RETURN</td>
</tr>
<tr>
<td>...</td>
<td>END</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE,CTN,COTANGENT)</td>
<td></td>
</tr>
</tbody>
</table>

Note that when TRIG is called with a second argument of SIN or COS, the function reference F(X) references the Fortran 95/90 library functions SIN and COS; but when TRIG is called with a second argument of CTN, F(X) references the user function CTN.
The following shows another example:

```fortran
INTRINSIC SIN, COS
REAL X, Y, R
! SIN and COS are arguments to Calc2:
R = Calc2 (SIN, COS)
```

**INUM**

*Elemental Intrinsic Function (Specific):*

*Converts a character string to an INTEGER(2) value. This function cannot be passed as an actual argument.*

**Syntax**

```fortran
result = INUM (i)
```

*i* 

(Input) Must be of type character.

**Results**

The result type is INTEGER(2). The result value is the INTEGER(2) value represented by the character string *i*.

**Example**

INUM ("451") has the value 451 of type INTEGER(2).

**IOR**

*Elemental Intrinsic Function (Generic):*

*Performs an inclusive OR on corresponding bits.
This function can also be specified as OR.*

**Syntax**

```fortran
result = IOR (i, j)
```
Input) Must be of type integer or of type logical (which is treated as an integer).

j
(Input) Must be of type integer with the same kind parameter as i. If the kinds of i and j do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

Results
The result type is the same as i. The result value is derived by combining i and j bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>i</th>
<th>j</th>
<th>IOR (i, j)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIOR</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIOR¹</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JIOR</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIOR</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

¹Or HIOR.

Example
IOR (1, 4) has the value 5.
IOR (1, 2) has the value 3.
The following shows another example:

```
INTEGER result
result = IOR(240, 90) ! returns 250
```

- NOT

**IPXFARGC**

*POSIX Function: Returns the index of the last command-line argument.*

**Module**

USE IFPOSIX

**Syntax**

```
result = IPXFARGC()
```

**Results**

The result type is INTEGER(4). The result value is the number of command-line arguments, excluding the command name, in the command used to invoke the executing program. A return value of zero indicates there are no command-line arguments other than the command name itself.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**
- H to I
- PXFGETARG
IPXFCONST

**POSIX Function:** Returns the value associated with a constant defined in the C POSIX standard.

**Module**
USE IFPOSIX

**Syntax**
result = IPXFCONST (constname)

constname (Input) Character. The name of a C POSIX standard constant.

**Results**
The result type is INTEGER(4). If constname corresponds to a defined constant in the C POSIX standard, the result value is the integer that is associated with the constant. Otherwise, the result value is -1.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**
- H to I
- PXFGETARG
- PXFCONST

IPXFLENTTRIM

**POSIX Function:** Returns the index of the last non-blank character in an input string.

**Module**
USE IFPOSIX

**Syntax**
result = IPXFLENTTRIM (string)

string (Input) Character. A character string.
Results

The result type is INTEGER(4). The result value is the index of the last non-blank character in the input argument string, or zero if all characters in string are blank characters.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

IPXFWEXITSTATUS (L*X, M*X)

POSIX Function: Returns the exit code of a child process.

Module

USE IFPOSIX

Syntax

result = IPXFWEXITSTATUS (istat)

istat (Input) INTEGER(4). The value of output argument istat from PXFWAIT or PXFWAITPID.

Results

The result type is INTEGER(4). The result is the low-order eight bits of the output argument of PXFWAIT or PXFWAITPID.

The IPXFWEXITSTATUS function should only be used if PXFWIFEXITED returns TRUE.
Example

program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
  print *, "I am a child process"
  print *, "My child's pid is", IPID_RET
  call PXFGETPPID(IPID_RET,IERROR)
  print *, "The pid of my parent is", IPID_RET
  print *, "Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
  print *, "I am a parent process"
  print *, "My parent pid is ", IPID_RET
  print *, "I am creating the process with pid", IPID
  print *, "Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
  print *, "The child with pid ", IPID_RET," has exited"
  if( PXFWIFEXITED(ISTAT) ) then
    print *, "The child exited normally"
    istat_ret = IPXFWEXITSTATUS(ISTAT)
    print 10, "The low byte of the child exit code is", istat_ret
  end if
end if
10 FORMAT (A,Z)
end program

**See Also**
- H to I
- PXFWAIT
- PXFWAITPID

**IPXFWSTOPSIG (L*X, M*X)**

**POSIX Function:** Returns the number of the signal that caused a child process to stop.

**Module**

USE IFPOSIX

**Syntax**

```fortran
result = IPXFWSTOPSIG (istat)
```

*istat* (Input) INTEGER(4). The value of output argument *istat* from PXFWAIT or PXFWAITPID.

**Results**

The result type is INTEGER(4). The result is the number of the signal that caused the child process to stop.

The IPXFWSTOPSIG function should only be used if PXFWIFSTOPPED returns TRUE.

**See Also**
- H to I
- PXFWAIT
- PXFWAITPID
- PXFWIFSTOPPED
IPXFWTERMSIG (L*X, M*X)

**POSIX Function:** Returns the number of the signal that caused a child process to terminate.

**Module**

USE IFPOSIX

**Syntax**

```fortran
result = IPXFWTERMSIG (istat)
```

*istat* (Input) INTEGER(4). The value of output argument *istat* from PXFWAIT or PXFWAITPID.

**Results**

The result type is INTEGER(4). The result is the number of the signal that caused the child process to terminate.

The IPXFWTERMSIG function should only be used if PXFWIFSIGNALED returns TRUE.

**See Also**

- H to I
- PXFWAIT
- PXFWAITPID
- PXFWIFSIGNALED

IRAND, IRANDM

**Portability Functions:** Return random numbers in the range 0 through (2**31)-1, or 0 through (2**15)-1 if called without an argument.

**Module**

USE IFPORT

**Syntax**

```fortran
result = IRAND ([iflag])
result = IRANDM ([iflag])
```
\( \text{iflag} \) (Input) INTEGER(4). Optional for IRAND. Controls the way the returned random number is chosen. If \( \text{iflag} \) is omitted, it is assumed to be 0, and the return range is 0 through \((2^{15})-1\) (inclusive).

**Results**

The result type is INTEGER(4). If \( \text{iflag} \) is 1, the generator is restarted and the first random value is returned. If \( \text{iflag} \) is 0, the next random number in the sequence is returned. If \( \text{iflag} \) is neither zero nor 1, it is used as a new seed for the random number generator, and the functions return the first new random value.

IRAND and IRANDM are equivalent and return the same random numbers. Both functions are included to ensure portability of existing code that references one or both of them.

You can use SRAND to restart the pseudorandom number generator used by these functions.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
USE IFPORT
INTEGER(4) istat, flag_value, r_nums(20)
flag_value=1
r_nums(1) = IRAND (flag_value)
flag_value=0
do istat=2,20
   r_nums(istat) = irand(flag_value)
end do
```

**See Also**

- SRAND

*Building Applications: Portability Library Overview*
IRANGET

**Portability Subroutine:** Returns the current seed.

**Module**

USE IFPORT

**Syntax**

CALL IRANGET (seed)

*seed* (Output) INTEGER(4). The current seed value.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- H to I
- IRANSET

IRANSET

**Portability Subroutine:** Sets the seed for the random number generator.

**Module**

USE IFPORT

**Syntax**

CALL IRANSET (seed)

*seed* (Input) INTEGER(4). The reset value for the seed.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- H to I
- IRANGET
**ISATTY**

*Portability Function:* Checks whether a logical unit number is a terminal.

---

**Module**

USE IFPORT

**Syntax**

result = ISATTY (lunit)

*Input* INTEGER(4). An integer expression corresponding to a Fortran logical unit number. Must be in the range 0 to 100 and must be connected.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if the specified logical unit is connected to a terminal device; otherwise, .FALSE..

If *lunit* is out of range or is not connected, zero is returned.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

---

**IS_IOSTAT_END**

*Elemental Intrinsic Function (Generic):* Tests for an end-of-file condition.

**Syntax**

result = IS_IOSTAT_END(i)

*i* (Input) Must be of type integer.

**Results**

The result type is default logical. The value of the result is true only if *i* is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-file condition.
Example
INTEGER IO_STATUS

READ (20, IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_END (IO_STATUS)) THEN
  ...  ! process end of file
ENDIF
...  ! process data read

IS_IOSTAT_EOR
Elemental Intrinsic Function (Generic): Tests for an end-of-record condition.

Syntax
result=IS_IOSTAT_EOR(i)
i               (Input) Must be of type integer.

Results
The result type is default logical. The value of the result is true only if i is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-record condition.

Example
INTEGER IO_STATUS

READ (30, ADVANCE='YES', IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_EOR (IO_STATUS)) THEN
  ...  ! process end of record
ENDIF
...  ! process data read
ISHA

**Elemental Intrinsic Function (Generic):**
Arithmetically shifts an integer left or right by a specified number of bits.

**Syntax**

```
result = ISHA (i, shift)
```

- **i** (Input) Must be of type integer. This argument is the value to be shifted.
- **shift** (Input) Must be of type integer. This argument is the direction and distance of shift. Positive shifts are left (toward the most significant bit); negative shifts are right (toward the least significant bit).

**Results**

The result type is the same as `i`. The result is equal to `i` shifted arithmetically by `shift` bits.

- If `shift` is positive, the shift is to the left; if `shift` is negative, the shift is to the right. If `shift` is zero, no shift is performed.
- Bits shifted out from the left or from the right, as appropriate, are lost. If the shift is to the left, zeros are shifted in on the right. If the shift is to the right, copies of the sign bit (0 for non-negative `i`; 1 for negative `i`) are shifted in on the left.
- The kind of integer is important in arithmetic shifting because sign varies among integer representations (see the following example). If you want to shift a one-byte or two-byte argument, you must declare it as INTEGER(1) or INTEGER(2).

**Example**

```
INTEGER(1) i, res1
INTEGER(2) j, res2
i = -128 ! equal to 10000000
j = -32768 ! equal to 10000000 00000000
res1 = ISHA (i, -4) ! returns 11111000 = -8
res2 = ISHA (j, -4) ! returns 11111000 10100000 = -2048
```
**See Also**
- H to I
- ISHC
- ISHL
- ISHFT
- ISHFTC

**ISHC**

*Elemental Intrinsic Function (Generic):* Rotates an integer left or right by specified number of bits. Bits shifted out one end are shifted in the other end. No bits are lost.

**Syntax**

```fortran
result = ISHC (i, shift)
```

- **i** (Input) Must be of type integer. This argument is the value to be rotated.
- **shift** (Input) Must be of type integer. This argument is the direction and distance of rotation.
  
  Positive rotations are left (toward the most significant bit); negative rotations are right (toward the least significant bit).

**Results**

The result type is the same as *i*. The result is equal to *i* circularly rotated by *shift* bits.

If *shift* is positive, *i* is rotated left *shift* bits. If *shift* is negative, *i* is rotated right *shift* bits. Bits shifted out one end are shifted in the other. No bits are lost.

The kind of integer is important in circular shifting. With an INTEGER(4) argument, all 32 bits are shifted. If you want to rotate a one-byte or two-byte argument, you must declare it as INTEGER(1) or INTEGER(2).
Example

```fortran
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10  ! equal to 00001010
j = 10  ! equal to 00000000 00001010
res1 = ISHC (i, -3)  ! returns 01000001 = 65
res2 = ISHC (j, -3)  ! returns 01000000 00000001 =
                     ! 16385
```

See Also

- ISHA
- ISHL
- ISHFT
- ISHFTC

**ISHFT**

**Elemental Intrinsic Function (Generic):**

*Performs a logical shift.*

**Syntax**

```fortran
result = ISHFT (i, shift)
```

- `i` (Input) Must be of type integer.
- `shift` (Input) Must be of type integer. The absolute value for `shift` must be less than or equal to `BIT_SIZE(i)`.

**Results**

The result type is the same as `i`. The result has the value obtained by shifting the bits of `i` by `shift` positions. If `shift` is positive, the shift is to the left; if `shift` is negative, the shift is to the right. If `shift` is zero, no shift is performed.

Bits shifted out from the left or from the right, as appropriate, are lost. Zeros are shifted in from the opposite end.
ISHFT with a positive *shift* can also be specified as `LSHIFT` (or `LSHFT`). ISHFT with a negative *shift* can also be specified as `RSHIFT` (or `RSHFT`) with `| shift |`.

For more information on bit functions, see [Bit Functions](#).

The model for the interpretation of an integer value as a sequence of bits is shown in [Model for Bit Data](#).

**ISHFTC**

*Elemental Intrinsic Function (Generic):*

*Performs a circular shift of the rightmost bits.*

**Syntax**

\[
\text{result} = \text{ISHFTC}(i, shift[, size])
\]

- **i** (Input) Must be of type integer.
- **shift** (Input) Must be of type integer. The absolute value of **shift** must be less than or equal to **size**.
- **size** (Input;optional) Must be of type integer. The value of **size** must be positive and must not exceed **BIT_SIZE(i)**. If **size** is omitted, it is assumed to have the value of **BIT_SIZE(i)**.

**Results**

The result type is the same as **i**. The result value is obtained by circular shifting the **size** rightmost bits of **i** by **shift** positions. If **shift** is positive, the shift is to the left; if **shift** is negative, the shift is to the right. If **shift** is zero, no shift is performed.

No bits are lost. Bits in **i** beyond the value specified by **size** are unaffected.

For more information on bit functions, see **Bit Functions**.

The model for the interpretation of an integer value as a sequence of bits is shown in **Model for Bit Data**.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSHFTC</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>

<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JISHFTC</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KISHFTC</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>
ISHFTC (4, 2, 4) has the value 1.
ISHFTC (3, 1, 3) has the value 6.

The following shows another example:

```
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10 ! equal to 00001010
j = 10 ! equal to 00000000 00001010
res1 = ISHFTC (i, 2, 3) ! rotates the 3 rightmost
    ! bits by 2 (left) and
    ! returns 00001001 = 9
res1 = ISHFTC (i, -2, 3) ! rotates the 3 rightmost
    ! bits by -2 (right) and
    ! returns 00001100 = 12
res2 = ISHFTC (j, 2, 3) ! rotates the 3 rightmost
    ! bits by 2 and returns
    ! 00000000 00001001 = 9
```
**ISHL**

**Elemental Intrinsic Function (Generic):**

Logically shifts an integer left or right by the specified bits. Zeros are shifted in from the opposite end.

**Syntax**

result = ISHL (i, shift)

- **i**  
  (Input) Must be of type integer. This argument is the value to be shifted.

- **shift**  
  (Input) Must be of type integer. This argument is the direction and distance of shift. If positive, *i* is shifted left (toward the most significant bit). If negative, *i* is shifted right (toward the least significant bit).

**Results**

The result type is the same as *i*. The result is equal to *i* logically shifted by *shift* bits. Zeros are shifted in from the opposite end.

Unlike circular or arithmetic shifts, which can shift ones into the number being shifted, logical shifts shift in zeros only, regardless of the direction or size of the shift. The integer kind, however, still determines the end that bits are shifted out of, which can make a difference in the result (see the following example).

**Example**

```fortran
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10  ! equal to 00001010
j = 10  ! equal to 00000000 00001010
res1 = ISHL (i, 5)  ! returns 01000000 = 64
res2 = ISHL (j, 5)  ! returns 00000001 01000000 = 320
```

ISNAN

*Elemental Intrinsic Function (Generic):* Tests whether IEEE* real (S_floating, T_floating, and X_floating) numbers are Not-a-Number (NaN) values.

**Syntax**

\[
\text{result} = \text{ISNAN} (x)
\]

\(x\) (Input) Must be of type real.

**Results**

The result type is default logical. The result is .TRUE. if \(x\) is an IEEE NaN; otherwise, the result is .FALSE..

**Example**

```
LOGICAL A
DOUBLE PRECISION B

... 
A = ISNAN(B)
```

A is assigned the value .TRUE. if B is an IEEE NaN; otherwise, the value assigned is .FALSE..

**ITIME**

*Portability Subroutine:* Returns the time in numeric form.

**Module**

```
USE IFPORT
```

**Syntax**

```
CALL ITIME (array)
```
array

(Output) INTEGER(4). A rank one array with three elements used to store numeric time data:

- array(1) - the hour
- array(2) - the minute
- array(3) - the second

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT

INTEGER(4) time_array(3)
CALL ITIME (time_array)
write(*,10) time_array
10 format (1X,I2,:,I2,:,I2)
END

Building Applications: Portability Library Overview

IVDEP

General Compiler Directive: Assists the compiler’s dependence analysis of iterative DO loops.

Syntax

cDEC$ IVDEP [: option]

c
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

option
Is LOOP or BACK. This argument is only available on processors using IA-32 architecture.
Description

The IVDEP directive is an assertion to the compiler's optimizer about the order of memory references inside a DO loop.

IVDEP:LOOP implies no loop-carried dependencies. IVDEP:BACK implies no backward dependencies.

When no option is specified, the following occurs:

- On IA-64 architecture, the behavior is the same as IVDEP:BACK. You can modify the behavior to be the same as IVDEP:LOOP by using a compiler option.
- On Intel® 64 architecture and IA-32 architecture, the compiler begins dependence analysis by assuming all dependences occur in the same forward direction as their appearance in the normal scalar execution order. This contrasts with normal compiler behavior, which is for the dependence analysis to make no initial assumptions about the direction of a dependence.

`!DEC$ IVDEP` with no option can also be spelled `!DEC$ INIT_DEP_FWD` (INITialize DEPendences ForWarD).

The IVDEP directive is applied to a DO loop in which the user knows that dependences are in lexical order. For example, if two memory references in the loop touch the same memory location and one of them modifies the memory location, then the first reference to touch the location has to be the one that appears earlier lexically in the program source code. This assumes that the right-hand side of an assignment statement is "earlier" than the left-hand side.

The IVDEP directive informs the compiler that the program would behave correctly if the statements were executed in certain orders other than the sequential execution order, such as executing the first statement or block to completion for all iterations, then the next statement or block for all iterations, and so forth. The optimizer can use this information, along with whatever else it can prove about the dependences, to choose other execution orders.

Example

In the following example, the IVDEP directive provides more information about the dependences within the loop, which may enable loop transformations to occur:

```fortran
!DEC$ IVDEP
   DO I=1, N
      A(INDARR(I)) = A(INDARR(I)) + B(I)
   END DO
```
In this case, the scalar execution order follows:

1. Retrieve INDARR(I).
2. Use the result from step 1 to retrieve A(INDARR(I)).
4. Add the results from steps 2 and 3.
5. Store the results from step 4 into the location indicated by A(INDARR(I)) from step 1.

IVDEP directs the compiler to initially assume that when steps 1 and 5 access a common memory location, step 1 always accesses the location first because step 1 occurs earlier in the execution sequence. This approach lets the compiler reorder instructions, as long as it chooses an instruction schedule that maintains the relative order of the array references.

- H to I
- General Compiler Directives
- Rules for General Directives that Affect DO Loops

**IXOR**

*Elemental Intrinsic Function (Generic):* See *IEOR.*

**J to L**

**JABS**

*Portability Function: Returns an absolute value.*

**Module**

USE IFPORT

**Syntax**

```plaintext
result = JABS (i)
i
```

(Input) INTEGER(4). A value.

**Results**

The result type is INTEGER(4). The value of the result is |i|.
**JDAT**

*Portability Function:* Returns an 8-character string with the Julian date in the form "yyddd". Three spaces terminate this string.

**Module**

USE IFPORT

**Syntax**

result = JDATE()

**Results**

The result type is character with length 8. The result is the Julian date, in the form YYDDD, followed by three spaces.

The Julian date is a five-digit number whose first two digits are the last two digits of the year, and whose final three digits represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 99032.

**CAUTION.** The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

! Sets julian to today's julian date

    USE IFPORT
    CHARACTER*8 julian
    julian = JDATE(

**See Also**

- J to L
- DATE_AND_TIME
**JDATE4**

**Portability Function:** Returns a 10-character string with the Julian date in the form "yyyyddd". Three spaces terminate this string.

**Module**

USE IFPORT

**Syntax**

result = JDATE4( )

**Results**

The result type is character with length 10. The result is the Julian date, in the form YYYYDDD, followed by three spaces.

The Julian date is a seven-digit number whose first four digits are the year, and whose final three represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 1999032.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- J to L
- DATE_AND_TIME

**JNUM**

**Elemental Intrinsic Function (Specific):**

Converts a character string to an INTEGER(4) value. This function cannot be passed as an actual argument.

**Syntax**

result = JNUM (i)

i       (Input) Must be of type character.
Results
The result type is INTEGER(4). The result value is the integer value represented by the character string i.

Example
JNUM ("46616") has the value 46616 of type INTEGER(4).

KILL
*Portability Function: Sends a signal to the process given by ID.*

Module
USE IFPORT

Syntax
result = KILL (pid, signum)

pid (Input) INTEGER(4). ID of a process to be signaled.
signum (Input) INTEGER(4). A signal value. For the definition of signal values, see the SIGNAL function.

Results
The result type is INTEGER(4). The result is zero if the call was successful; otherwise, an error code. Possible error codes are:

- EINVAL: The signum is not a valid signal number, or PID is not the same as getpid( ) and signum does not equal SIGKILL.
- ESRCH: The given PID could not be found.
- EPERM: The current process does not have permission to send a signal to the process given by PID.

On Windows* systems, arbitrary signals can be sent only to the calling process (where pid= getpid( )). Other processes can send only the SIGKILL signal ( signum= 9), and only if the calling process has permission.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**Example**

USE IFPORT

integer(4) id_number, sig_val, istat

id_number = getpid()

ISTAT = KILL (id_number, sig_val)

**See Also**
- J to L
- SIGNAL
- RAISEQQ
- SIGNALQQ

*Building Applications: Portability Library Overview*

**KIND**

*Inquiry Intrinsic Function (Generic): Returns the kind parameter of the argument.*

**Syntax**

\[
\text{result} = \text{KIND} (x)
\]

\[x\]  
(Input) Can be of any intrinsic type.

**Results**

The result is a scalar of type default integer. The result has a value equal to the kind type parameter value of \(x\).

**Example**

KIND (0.0) has the kind value of default real type.

KIND (12) has the kind value of default integer type.
The following shows another example:

```
INTEGER i ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2( )
WRITE(*,*) KIND(i) ! still a 4-byte integer
                   ! not affected by setting in subroutine
END

SUBROUTINE INTEGER2( )
  !DEC$INTEGER:2
  INTEGER j ! a 2-byte integer
  WRITE(*,*) KIND(j)
END SUBROUTINE
```

**See Also**
- J to L
- SELECTED_INT_KIND
- SELECTED_REAL_KIND

**KNUM**

_Elmental Intrinsic Function (Specific):_

_Converts a character string to an INTEGER(8) value._

**Syntax**

```
result = KNUM (i)
```

\( i \) (Input) Must be of type character.
Results
The result type is INTEGER(8). The result value is the integer value represented by the character string i.

Example
KNUM ("46616") has the value 46616 of type INTEGER(8).

LASTPRIVATE
Parallel Directive Clause: Provides a superset of the functionality provided by the PRIVATE clause; objects are declared PRIVATE and they are given certain values when the parallel region is exited.

Syntax
LASTPRIVATE (list)
list Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, once the parallel region is exited, each variable has the value provided by the sequentially last section or loop iteration.

When the LASTPRIVATE clause appears in a DO directive, the thread that executes the sequentially last iteration updates the version of the object it had before the construct. When the LASTPRIVATE clause appears in a SECTIONS directive, the thread that executes the lexically last SECTION updates the version of the object it had before the construct.

Subobjects that are not assigned a value by the last iteration of the DO or the lexically last SECTION of the SECTIONS directive are undefined after the construct.
LBOUND

**Inquiry Intrinsic Function (Generic):** Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.

**Syntax**

\[
\text{result} = \text{LBOUND}(\text{array}[, \text{dim}][, \text{kind}])
\]

- **array** (Input) Must be an array. It may be of any data type. It must not be an allocatable array that is not allocated, or a disassociated pointer.
- **dim** (Input; optional) Must be a scalar integer initialization expression.
- **kind** (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is integer. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If **dim** is present, the result is a scalar. Otherwise, the result is a rank-one array with one element for each dimension of **array**. Each element in the result corresponds to a dimension of **array**.

If **array** is an array section or an array expression that is not a whole array or array structure component, each element of the result has the value 1.

If **array** is a whole array or array structure component, LBOUND( **array**, **dim**) has a value equal to the lower bound for subscript **dim** of **array** (if **dim** is nonzero or **array** is an assumed-size array of rank **dim**). Otherwise, the corresponding element of the result has the value 1.

The setting of compiler options specifying integer size can affect this function.

**Example**

Consider the following:

\[
\begin{align*}
\text{REAL ARRAY\_A (1:3, 5:8)} \\
\text{REAL ARRAY\_B (2:8, -3:20)}
\end{align*}
\]

LBOUND(ARRAY\_A) is (1, 5). LBOUND(ARRAY\_A, DIM=2) is 5.
LBOUND(ARRAY_B) is (2, -3). LBOUND(ARRAY_B (5:8, :)) is (1, 1) because the arguments are array sections.

The following shows another example:

```fortran
REAL ar1(2:3, 4:5, -1:14), vec1(35)
INTEGER res1(3), res2, res3(1)
res1 = UBOUND (ar1) ! returns [2, 4, -1]
res2 = UBOUND (ar1, DIM= 3) ! returns -1
res3 = UBOUND (vec1) ! returns [1]
END
```

See Also
- J to L
- UBOUND

**LCWRQQ**

*Portability Subroutine: Sets the value of the floating-point processor control word.*

**Module**

USE IFPORT

**Syntax**

```fortran
CALL LCWRQQ (controlword)
```

*controlword* (Input) INTEGER(2). Floating-point processor control word.

LCWRQQ performs the same function as the run-time subroutine SETCONTROLFPQQ and is provided for compatibility.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

INTEGER(2) control

CALL SCWROQQ(control) ! get control word
! Set control word to make processor round up
control = control .AND. (.NOT. FPCW$MCW_RC) ! Clear
! control word with inverse
! of rounding control mask

control = control .OR. FPCW$UP ! Set control word
! to round up

CALL LCWROQQ(control)

WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END

See Also
• J to L
• SETCONTROLFPQQ

LEADZ

Elemental Intrinsic Function (Generic):
Returns the number of leading zero bits in an integer.

Syntax

result = LEADZ (i)

i 
(Input) Must be of type integer or logical.

Results

The result type is the same as i. The result value is the number of leading zeros in the binary representation of the integer i.
The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example
Consider the following:

```fortran
INTEGER*8 J, TWO
PARAMETER (TWO=2)
DO J= -1, 40
   TYPE *, LEADZ(TWO**J)  ! Prints 64 down to 23 (leading zeros)
ENDDO
END
```

LEN

**Inquiry Intrinsic Function (Generic):** Returns the length of a character expression.

**Syntax**

```
result = LEN (string [, kind])
```

- **string** (Input) Must be of type character; it can be scalar or array valued.
  (It can be an array of strings.)
- **kind** (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result is a scalar of type integer. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result has a value equal to the number of characters in **string** (if it is scalar) or in an element of **string** (if it is array valued).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEN (^1)</td>
<td>CHARACTER</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>
The setting of compiler options specifying integer size can affect this function.

Example
Consider the following example:

```fortran
CHARACTER (15) C (50)

CHARACTER (25) D

LEN (C) has the value 15, and LEN (D) has the value 25.

The following shows another example:
CHARACTER (11) STR (100)

INTEGER I

I = LEN (STR)  ! returns 11
I = LEN ('A phrase with 5 trailing blanks. ')  
   ! returns 37
```

See Also
- J to L
- LEN_TRIM
- Declaration Statements for Character Types
- Character Data Type

LEN_TRIM

**Elemental Intrinsic Function (Generic):**

*Returns the length of the character argument without counting trailing blank characters.*

**Syntax**

```fortran
result = LEN_TRIM (string [, kind])
```

- `string` (Input) Must be of type character.
- `kind` (Input; optional) Must be a scalar integer initialization expression.
Results

The result is a scalar of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result has a value equal to the number of characters remaining after any trailing blanks in string are removed. If the argument contains only blank characters, the result is zero.

The setting of compiler options specifying integer size can affect this function.

Example

LEN_TRIM (' C D ') has the value 4.
LEN_TRIM (' ') has the value 0.

The following shows another example:

```
INTEGER LEN1
LEN1 = LEN_TRIM (' GOOD DAY ') ! returns 9
LEN1 = LEN_TRIM (' ') ! returns 0
```

See Also

- J to L
- LEN
- LNBLNK

LGE

Elemental Intrinsic Function (Generic):
Determines if a string is lexically greater than or equal to another string, based on the ASCII collating sequence, even if the processor’s default collating sequence is different. In Intel® Fortran, LGE is equivalent to the (.GE.) operator.

Syntax

```
result = LGE (string_a,string_b)
```

string_a (Input) Must be of type character.
string_b (Input) Must be of type character.
Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if the strings are equal, both strings are of zero length, or if \texttt{string\_a} follows \texttt{string\_b} in the ASCII collating sequence; otherwise, the result is false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LGE (^1,^2)</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

\(^1\) This specific function cannot be passed as an actual argument.

\(^2\) The setting of compiler options specifying integer size can affect this function.

Example

LGE ( 'ONE', 'SIX' ) has the value false.

LGE ( 'TWO', 'THREE' ) has the value true.

The following shows another example:

```fortran
LOGICAL L
L = LGE('ABC','ABD') ! returns .FALSE.
L = LGE ('AB', 'AAAAAAAB') ! returns .TRUE.
```

LGT

\textit{Elemental Intrinsic Function (Generic):}

\textit{Determines whether a string is lexically greater than another string, based on the ASCII collating sequence.}
sequence, even if the processor’s default collating sequence is different. In Intel® Fortran, LGT is equivalent to the > (.GT.) operator.

Syntax

result = LGT (string_a, string_b)

string_a (Input) Must be of type character.
string_b (Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if string_a follows string_b in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LGT 1,2</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

1 This specific function cannot be passed as an actual argument.

2 The setting of compiler options specifying integer size can affect this function.

Example

LGT ( 'TWO', 'THREE' ) has the value true.
LGT ( 'ONE', 'FOUR' ) has the value true.

The following shows another example:

LOGICAL L
L = LGT('ABC', 'ABC') ! returns .FALSE.
L = LGT('ABC', 'AABC') ! returns .TRUE.

LINETO, LINETO_W (W*32, W*64)

Graphics Function: Draws a line from the current graphics position up to and including the end point.

Module
USE IFQWIN

Syntax
result = LINETO (x, y)
result = LINETO_W (wx, wy)

x, y (Input) INTEGER(2). Viewport coordinates of end point.
wx, wy (Input) REAL(8). Window coordinates of end point.

Results
The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0.
The line is drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.
If no error occurs, LINETO sets the current graphics position to the viewport point (x, y), and LINETO_W sets the current graphics position to the window point (wx, wy).
If you use FLOODFILLRGB to fill in a closed figure drawn with LINETO, the figure must be drawn with a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

NOTE. The LINETO routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the LineTo routine by including the IFWIN module, you need to specify the routine name as MSFWIN$LineTo. For more information, see Building Applications: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS
Example

This program draws the figure shown below.

! Build as QuickWin or Standard Graphics

USE IFQWIN

INTEGER(2) status

TYPE (xycoord) xy

CALL MOVETO(INT2(80), INT2(50), xy)

status = LINETO(INT2(240), INT2(150))

status = LINETO(INT2(240), INT2(50))

END

Building Applications: Drawing Lines on the Screen

Building Applications: Graphics Coordinates
LINETOAR (W32, W64)

Graphics Function: Draws a line between each x,y point in the from-array to each corresponding x,y point in the to-array.

Module
USE IFQWIN

Syntax
result = LINETOAR(loc(fx), loc(fy), loc(tx) loc(ty), cnt)

fx (Input) INTEGER(2). From x viewport coordinate array.
fy (Input) INTEGER(2). From y viewport coordinate array.
tx (Input) INTEGER(2). To x viewport coordinate array.
ty (Input) INTEGER(2). To y viewport coordinate array.
cnt (Input) INTEGER(4). Length of each coordinate array; all should be the same size.

Results
The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, zero.

The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS
Example

! Build for QuickWin or Standard Graphics
USE IFQWIN

integer(2) fx(3), fy(3), tx(3), ty(3), result
integer(4) cnt, i
! load the points
do i = 1,3
  ! from here
  fx(i) = 20*i
  fy(i) = 10
  ! to there
  tx(i) = 20*i
  ty(i) = 60
end do
! draw the lines all at once
! 3 white vertical lines in upper left corner
result = LINETOAR(loc(fx), loc(fy), loc(tx), loc(ty), 3)
end

*Building Applications*: Drawing Lines on the Screen
LINETOAREX (W*32, W*64)

Graphics Function: Draws a line between each x,y point in the from-array to each corresponding x,y point in the to-array. Each line is drawn with the specified graphics color and line style.

Module

USE IFQWIN

Syntax

result = LINETOAREX (loc(fx), loc(fy), loc(tx) loc(ty), loc(C), loc(S), cnt)

fx (Input) INTEGER(2). From x viewport coordinate array.
fy (Input) INTEGER(2). From y viewport coordinate array.
tx (Input) INTEGER(2). To x viewport coordinate array.
ty (Input) INTEGER(2). To y viewport coordinate array.
C (Input) INTEGER(4). Color array.
S (Input) INTEGER(4). Style array.
cnt (Input) INTEGER(4). Length of each coordinate array; also the length of the color array and style array. All of the arrays should be the same size.

Results

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, zero.
The lines are drawn using the specified graphics colors and line styles, and with the current write mode. The current write mode is set with SETWRITEMODE.
If the color has the Z'80000000' bit set, the color is an RGB color; otherwise, the color is a palette color.
The styles are as follows from wingdi.h:

<table>
<thead>
<tr>
<th>Style</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOLID</td>
<td>0</td>
</tr>
<tr>
<td>DASH</td>
<td>1     /* ------- */</td>
</tr>
<tr>
<td>DOT</td>
<td>2     /* ....... */</td>
</tr>
<tr>
<td>DASHDOT</td>
<td>3     /* <em>.</em>.<em>.</em> */</td>
</tr>
<tr>
<td>DASHDOTDOT</td>
<td>4     /* <em>..</em>.._ */</td>
</tr>
<tr>
<td>NULL</td>
<td>5</td>
</tr>
</tbody>
</table>

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS
Example

! Build for QuickWin or Standard Graphics
USE IFQWIN
integer(2) fx(3),fy(3),tx(3),ty(3),result
integer(4) C(3),S(3),cnt,i,color
color = #000000FF
! load the points
do i = 1,3
  S(i) = 0 ! all lines solid
  C(i) = IOR(Z'80000000',color)
  color = color*256 ! pick another of RGB
  if(IAND(color,Z'00FFFFFF').eq.0) color = Z'000000FF'
!from here
  fx(i) =20*i
  fy(i) =10
  !to there
  tx(i) =20*i
  ty(i) =60
end do
! draw the lines all at once
! 3 vertical lines in upper left corner, Red, Green, and Blue
result = LINETOAREX(loc(fx),loc(fy),loc(tx),loc(ty),loc(C),loc(S),3)
end

LLE

Elemental Intrinsic Function (Generic):
Determines whether a string is lexically less than or equal to another string, based on the ASCII collating sequence, even if the processor's default collating sequence is different. In Intel® Fortran, LLE is equivalent to the (.LE.) operator.

Syntax

\[
\text{result} = \text{LLE} (\text{string}_a, \text{string}_b)
\]

\(\text{string}_a\) (Input) Must be of type character.

\(\text{string}_b\) (Input) Must be of type character.

Results

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if the strings are equal, both strings are of zero length, or if \(\text{string}_a\) precedes \(\text{string}_b\) in the ASCII collating sequence; otherwise, the result is false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLE (^1,2)</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

\(^1\) This specific function cannot be passed as an actual argument.

\(^2\) The setting of compiler options specifying integer size can affect this function.

Example

LLE ( 'TWO', 'THREE' ) has the value false.

LLE ( 'ONE', 'FOUR' ) has the value false.
The following shows another example:

```fortran
LOGICAL L
L = LLE('ABC', 'ABC')  ! returns .TRUE.
L = LLE('ABC', 'AABCD') ! returns .FALSE.
```

**See Also**

**LLT**

**Elemental Intrinsic Function (Generic):**

Determines whether a string is lexically less than another string, based on the ASCII collating sequence, even if the processor’s default collating sequence is different. In Intel® Fortran, LLT is equivalent to the < (.LT.) operator.

**Syntax**

```
result = LLT (string_a, string_b)
```

- `string_a` (Input) Must be of type character.
- `string_b` (Input) Must be of type character.

**Results**

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if `string_a` precedes `string_b` in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLT ¹,²</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

¹ Available in Fortran 77 and later.
² Available in Fortran 90 and later.

[119x657]
Specific Name | Argument Type | Result Type
--- | --- | ---
1 This specific function cannot be passed as an actual argument.
2 The setting of compiler options specifying integer size can affect this function.

**Example**

LLT ( 'ONE', 'SIX' ) has the value true.
LLT ( 'ONE', 'FOUR' ) has the value false.

The following shows another example:

```fortran
LOGICAL L
L = LLT ('ABC', 'ABC') ! returns .FALSE.
L = LLT ('AAXYZ', 'ABCDE') ! returns .TRUE.
```

**LNBLNK**

*Portability Function: Locates the position of the last nonblank character in a string.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = LNBLNK (string)
```

*string (Input) Character*(*). String to be searched. Cannot be an array.

**Results**

The result type is INTEGER(4). The result is the index of the last nonblank character in string.
LNBLNK is very similar to the intrinsic function LEN_TRIM, except that *string* cannot be an array.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFPORT

integer(4) p

p = LNBLNK('GOOD DAY') ! returns 9

p = LNBLNK(' ') ! returns 0

**See Also**

- J to L
- LEN_TRIM

*Building Applications*: Portability Library Overview

**LOADIMAGE, LOADIMAGE_W (W*32, W*64)**

*Graphics Functions*: Read an image from a Windows bitmap file and display it at a specified location.

**Module**

USE IFQWIN

**Syntax**

result = LOADIMAGE (filename, xcoord, ycoord)

result = LOADIMAGE_W (filename, wxcoord, wycoord)

*filename* (Input) Character*(*) Path of the bitmap file.

*xcoord, ycoord* (Input) INTEGER(4). Viewport coordinates for upper-left corner of image display.

*wxcoord, wycoord* (Input) REAL(8). Window coordinates for upper-left corner of image display.
**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The image is displayed with the colors in the bitmap file. If the color palette in the bitmap file is different from the current system palette, the current palette is discarded and the bitmap's palette is loaded.

LOADIMAGE specifies the screen placement of the image in viewport coordinates. LOADIMAGE_W specifies the screen placement of the image in window coordinates.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**See Also**

- J to L
- SAVEIMAGE, SAVEIMAGE_W

*Building Applications: Loading and Saving Images to Files*

**LOC**

*Inquiry Intrinsic Function (Generic): Returns the internal address of a storage item. This function cannot be passed as an actual argument.*

**Syntax**

```
result = LOC (x)
```

- **x** (Input) Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

This function performs the same function as the %LOC built-in function.
Example

! Mixed language example passing Integer Pointer to C
! Fortran main program

```fortran
INTERFACE
  SUBROUTINE Ptr_Sub (p)
    !DEC$ ATTRIBUTES C, ALIAS:'_Ptr_Sub' :: Ptr_Sub
    INTEGER p
  END SUBROUTINE Ptr_Sub
END INTERFACE
END INTERFACE
REAL A[10], VAR[10]
POINTER (p, VAR) ! VAR is the pointer-based
  ! variable, p is the integer
  ! pointer
  p = LOC(A)
  CALL Ptr_Sub (p)
  WRITE(*,*) "A(4) = ", A(4)
END
```

! C subprogram

```c
void Ptr_Sub (int *p)
{
  float a[10];
  a[3] = 23.5;
  *p = a;
}
```

%LOC

**Built-in Function**: Computes the internal address of a storage item.

**Syntax**

```fortran
result = %LOC (a)
```
a

(Input) Is the name of an actual argument. It must be a variable, an expression, or the name of a procedure. It must not be the name of a statement function.

Description
The %LOC function produces an integer value that represents the location of the given argument. The value is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. You can use this integer value as an item in an arithmetic expression.

The LOC intrinsic function serves the same purpose as the %LOC built-in function.

LOG

Elemental Intrinsic Function (Generic):
Returns the natural logarithm of the argument.

Syntax
result = LOG (x)

x

(Input) Must be of type real or complex. If x is real, its value must be greater than zero. If x is complex, its value must not be zero.

Results
The result type is the same as x. The result value is approximately equal to log_e x.

If the arguments are complex, the result is the principal value with imaginary part omega in the range -pi <= omega <= pi.

If the real part of x < 0 and the imaginary part of x is a positive real zero, the imaginary part of the result is pi.

If the real part of x < 0 and the imaginary part of x is a negative real zero, the imaginary part of the result is -pi.

<table>
<thead>
<tr>

</tbody>
</table>
### Specific Name | Argument Type | Result Type
--- | --- | ---
CLOG ² | COMPLEX(4) | COMPLEX(4)
CDLOG³,⁴ | COMPLEX(8) | COMPLEX(8)
CQLOG | COMPLEX(16) | COMPLEX(16)

¹This function is treated like LOG.
²The setting of compiler options specifying real size can affect ALOG, LOG, and CLOG.
³This function can also be specified as ZLOG.
⁴The setting of compiler options specifying double size can affect CDLOG.

### Example

LOG (8.0) has the value 2.079442.
LOG (25.0) has the value 3.218876.
The following shows another example:

```fortran
REAL r
r = LOG(10.0) ! returns 2.302585
```

### See Also
- J to L
- EXP
- LOG10

### LOG10

**Elemental Intrinsic Function (Generic):**
*Returns the common logarithm of the argument.*

### Syntax

```
result = LOG10 (x)
```

- **x** (Input) Must be of type real or complex. If x is real, its value must be greater than zero. If x is complex, its value must not be zero.
**Results**

The result type is the same as \( x \). The result value is approximately equal to \( \log_{10} x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALOG10 (^{1,2})</td>

<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQLOG10</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

\(^1\) This function is treated like LOG10.

\(^2\) The setting of compiler options specifying real size can affect ALOG10, CLOG10, and LOG10.

\(^3\) The setting of compiler options specifying double size can affect DLOG10 and CDLOG10.

**Example**

LOG10 (8.0) has the value 0.9030900.

LOG10 (15.0) has the value 1.176091.

The following shows another example:

```fortran
REAL r
r = LOG10(10.0) ! returns 1.0
```

**See Also**

- J to L
- LOG
**LOGICAL Statement**

Statement: Specifies the LOGICAL data type.

**Syntax**

LOGICAL

LOGICAL([KIND=] \(n\))

LOGICAL*\(n\)

\(n\) Is kind 1, 2, 4, or 8.

If a kind parameter is specified, the logical constant has the kind specified. If no kind parameter is specified, the kind of the constant is default logical.

**Example**

LOGICAL, ALLOCATABLE :: flag1, flag2

LOGICAL (2), SAVE :: doit, dont=.FALSE.

LOGICAL switch

! An equivalent declaration is:

LOGICAL flag1, flag2

LOGICAL (2) doit, dont=.FALSE.

ALLOCATABLE flag1, flag2

SAVE doit, dont

**See Also**

- J to L
- Logical Data Types
- Logical Constants
- Data Types, Constants, and Variables
LOGICAL Function

Elemental Intrinsic Function (Generic):
Converts the logical value of the argument to a logical value with different kind parameters.

Syntax
result = LOGICAL (l[,kind])
l (Input) Must be of type logical.
kind (Input; optional) Must be a scalar integer initialization expression.

Results
The result is of type logical. If kind is present, the kind parameter is that specified by kind; otherwise, the kind parameter is that of default logical. The result value is that of l.
The setting of compiler options specifying integer size can affect this function.

Example
LOGICAL (L .OR. .NOT. L) has the value true and is of type default logical regardless of the kind parameter of logical variable L.
LOGICAL (.FALSE., 2) has the value false, with the kind parameter of INTEGER(KIND=2).

• J to L
• CMPLX
• INT
• REAL
• Logical Data Types

LONG

Portability Function: Converts an INTEGER(2) argument to INTEGER(4) type.

Module
USE IFPORT
Syntax

\[
\text{result} = \text{LONG (int2)}
\]

\( \text{int2} \) (Input) INTEGER(2). Value to be converted.

Results

The result type is INTEGER(4). The result is the value of \( \text{int2} \) with type INTEGER(4). The upper 16 bits of the result are zeros and the lower 16 are equal to \( \text{int2} \).

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also

- J to L
- INT
- KIND

Building Applications: Portability Library Overview

LOOP COUNT

**General Compiler Directive:** Specifies the iterations (count) for a DO loop.

Syntax

\[
\text{cDEC$ LOOP COUNT} (n1[,n2]...)
\]

\[
\text{cDEC$ LOOP COUNT=} n1[,n2]...\]

\[
\text{cDEC$ LOOP COUNT MAX}(n1), \text{MIN}(n1), \text{AVG}(n1)
\]

\[
\text{cDEC$ LOOP COUNT MAX}=n1, \text{MIN}=n1, \text{AVG}=n1
\]

\( c \) Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

\( n1, n2 \) Is a non-negative integer constant.

The value of the loop count affects heuristics used in software pipelining, vectorization, and loop-transformations.
### Argument Form

<table>
<thead>
<tr>
<th>Argument Form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$n1$, $n2$</td>
<td>Indicates that the next DO loop will iterate $n1$, $n2$, or some other number of times.</td>
</tr>
<tr>
<td>MAX, MIN, and AVG</td>
<td>Indicates that the next DO loop has the specified maximum, minimum, and average number ($n1$) of iterations.</td>
</tr>
</tbody>
</table>

### Example

Consider the following:

```plaintext
cDEC$ LOOP COUNT (10000)
doi =1,m

b(i) = a(i) + 1 ! This is likely to enable the loop to get software-pipelined
enddo
```

Note that you can specify more than one LOOP COUNT directive for a DO loop. For example, the following directives are valid:

```plaintext
!DEC$ LOOP COUNT (10, 20, 30)

!DEC$ LOOP COUNT MAX=100, MIN=3, AVG=17

DO
...
```

### See Also
- J to L
- Rules for General Directives that Affect DO Loops

*Optimizing Applications*: Loop Count and Loop Distribution
LSHIFT

Elemental Intrinsic Function (Generic): Shifts the bits in an integer left by a specified number of positions. See ISHFT.

LSTAT

Portability Function: Returns detailed information about a file.

Module

USE IFPORT

Syntax

\[
\text{result} = \text{LSTAT} \left( \text{name}, \text{statb} \right)
\]

name \hspace{0.5cm} \text{(Input)} \text{ Character*(*). Name of the file to examine.}

statb \hspace{0.5cm} \text{(Output)} \text{ INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. See STAT for the possible values returned in statb.}

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code (see IERRNO).

LSTAT returns detailed information about the file named in name.

On Linux* and Mac OS* X systems, if the file denoted by name is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.

On Windows* systems, LSTAT returns exactly the same information as STAT (because there are no symbolic links on these systems). STAT is the preferred function.

INQUIRE also provides information about file properties.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

INTEGER(4) info_array(12), istatus
character*20 file_name

print *, "Enter name of file to examine: ", file_name
read *, file_name
ISTATUS = LSTAT (file_name, info_array)
if (.NOT. ISTATUS) then
   print *, info_array
else
   print *, 'Error ', istatus
end if

See Also
- J to L
- INQUIRE
- GETFILEINFO
- STAT
- FSTAT

Building Applications: Portability Library Overview

LTIME

Portability Subroutine: Returns the components of the local time zone time in a nine-element array.

Module

USE IFPORT

Syntax

CALL LTIME (time, array)

(time) (Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.
**array** (Output) INTEGER(4). One-dimensional array with 9 elements to contain local date and time data derived from `time`. The elements of array are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>array(1)</td>
<td>Seconds (0 - 59)</td>
</tr>
<tr>
<td>array(2)</td>
<td>Minutes (0 - 59)</td>
</tr>
<tr>
<td>array(3)</td>
<td>Hours (0 - 23)</td>
</tr>
<tr>
<td>array(4)</td>
<td>Day of month (1 - 31)</td>
</tr>
<tr>
<td>array(5)</td>
<td>Month (0 - 11)</td>
</tr>
<tr>
<td>array(6)</td>
<td>Years since 1900</td>
</tr>
<tr>
<td>array(7)</td>
<td>Day of week (0 - 6, where 0 is Sunday)</td>
</tr>
<tr>
<td>array(8)</td>
<td>Day of year (1 - 365)</td>
</tr>
<tr>
<td>array(9)</td>
<td>1 if daylight saving time is in effect; otherwise, 0.</td>
</tr>
</tbody>
</table>

**CAUTION.** This subroutine is not year-2000 compliant, use DATE_AND_TIME instead.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

INTEGER(4) input_time, time_array(9)
! find number of seconds since 1/1/70
input_time=TIME()
! convert number of seconds to time array
CALL LTIME (input_time, time_array)
PRINT *, time_array

See Also

• J to L
• DATE_AND_TIME

Building Applications: Portability Library Overview

M to N

MAKEDIRQQ

Portability Function: Creates a new directory with a specified name.

Module

USE IFPORT

Syntax

result = MAKEDIRQQ (dirname)

dirname (Input) Character*(*) Name of directory to be created.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

MAKEDIRQQ can create only one directory at a time. You cannot create a new directory and a subdirectory below it in a single command. MAKEDIRQQ does not translate path delimiters. You can use either slash (/) or backslash (\) as valid delimiters.

If an error occurs, call GETLASTERRORQQ to retrieve the error message. Possible errors include:
• ERR$ACCES - Permission denied. The file's (or directory's) permission setting does not allow the specified access.
• ERR$EXIST - The directory already exists.
• ERR$NOENT - The file or path specified was not found.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
LOGICAL(4) result
result = MAKEDIRQQ('mynewdir')
IF (result) THEN
  WRITE (*,*) 'New subdirectory successfully created'
ELSE
  WRITE (*,*) 'Failed to create subdirectory'
END IF
END

See Also
• M to N
• DELDIRQQ
• CHANGEDIRQQ
• GETLASTERRORQQ

MALLOCC

Elemental Intrinsic Function (Generic):
Allocates a block of memory. This is a generic function that has no specific function associated with it. It must not be passed as an actual argument.

Syntax

result = MALLOCC (size)
size (Input) Must be of type integer. This value is the size (in bytes) of memory to be allocated.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. The result is the starting address of the allocated memory. The memory allocated can be freed by using the FREE intrinsic function.

Example
INTEGER(4) SIZE
REAL(4) STORAGE(*)
POINTER (ADDR, STORAGE) ! ADDR will point to STORAGE
SIZE = 1024 ! Size in bytes
ADDR = MALLOC(SIZE) ! Allocate the memory
CALL FREE(ADDR) ! Free it
**MAP...END MAP**

**Statement:** Specifies mapped field declarations that are part of a UNION declaration within a STRUCTURE declaration. See STRUCTURE.

**Example**

```
UNION
    MAP
        CHARACTER*20 string
    END MAP
    MAP
        INTEGER*2 number(10)
    END MAP
END UNION
UNION
    MAP
        RECORD /Cartesian/ xcoord, ycoord
    END MAP
    MAP
        RECORD /Polar/ length, angle
    END MAP
END UNION
```

**MASTER**

**OpenMP Fortran Compiler Directive:** Specifies a block of code to be executed by the master thread of the team.

**Syntax**

```
c$OMP MASTER
    block
```
c$OMP END MASTER

c
Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

block
Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

When the MASTER directive is specified, the other threads in the team skip the enclosed block (section) of code and continue execution. There is no implied barrier, either on entry to or exit from the master section.

Example
The following example forces the master thread to execute the routines OUTPUT and INPUT:

```fortran
  c$OMP PARALLEL DEFAULT(SHARED)
    CALL WORK(X)
  c$OMP MASTER
    CALL OUTPUT(X)
    CALL INPUT(Y)
  c$OMP END MASTER
    CALL WORK(Y)
  c$OMP END PARALLEL
```

See Also
- M to N
- OpenMP Fortran Compiler Directives

MATMUL

Transformational Intrinsic Function (Generic):
Performs matrix multiplication of numeric or logical matrices.

Syntax
```
result = MATMUL (matrix_a, matrix_b)
```

- `matrix_a` (Input) Must be an array of rank one or two. It must be of numeric (integer, real, or complex) or logical type.
matrix_b

(Input) Must be an array of rank one or two. It must be of numeric type if matrix_a is of numeric type or logical type if matrix_a is logical type.
At least one argument must be of rank two. The size of the first (or only) dimension of matrix_b must equal the size of the last (or only) dimension of matrix_a.

Results

The result is an array whose type depends on the data type of the arguments, according to the rules described in Data Type of Numeric Expressions. The rank and shape of the result depends on the rank and shapes of the arguments, as follows:

- If matrix_a has shape (n, m) and matrix_b has shape (m, k), the result is a rank-two array with shape (n, k).
- If matrix_a has shape (m) and matrix_b has shape (m, k), the result is a rank-one array with shape (k).
- If matrix_a has shape (n, m) and matrix_b has shape (m), the result is a rank-one array with shape (n).

If the arguments are of numeric type, element (i, j) of the result has the value SUM((row i of matrix_a) * (column j of matrix_b)). If the arguments are of logical type, element (i, j) of the result has the value ANY((row i of matrix_a) .AND. (column j of matrix_b)).

Example

A is matrix

\[
\begin{bmatrix}
2 & 3 & 4 \\
3 & 4 & 5
\end{bmatrix},
\]

B is matrix

\[
\begin{bmatrix}
2 & 3 \\
3 & 4 \\
4 & 5
\end{bmatrix},
\]

X is vector (1, 2), and Y is vector (1, 2, 3).

The result of MATMUL (A, B) is the matrix-matrix product AB with the value

\[
\begin{bmatrix}
29 & 38 \\
38 & 50
\end{bmatrix}.
\]
The result of `MATMUL (X, A)` is the vector-matrix product `XA` with the value `(8, 11, 14)`.

The result of `MATMUL (A, Y)` is the matrix-vector product `AY` with the value `(20, 26)`.

The following shows another example:

```fortran
INTEGER a(2,3), b(3,2), c(2), d(3), e(2,2), f(3), g(2)
a = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
  ! a is 1 3 5
  ! 2 4 6
b = RESHAPE((/1, 2, 3, 4, 5, 6/), (/3, 2/))
  ! b is 1 4
  ! 2 5
  ! 3 6
c = (/1, 2/)     ! c is [1 2]
d = (/1, 2, 3/)   ! d is [1 2 3]
e = MATMUL(a, b) ! returns 22 49
  ! 28 64
f = MATMUL(c,a)  ! returns [5 11 17]
g = MATMUL(a,d)  ! returns [22 28]
WRITE(*,*) e, f, g
END
```

**See Also**

- `PRODUCT`

**MAX**

*Elemental Intrinsic Function (Generic):*

*Returns the maximum value of the arguments.*

**Syntax**

```
result = MAX (a1,a2[,a3]...)
```
All must have the same type (integer or real) and kind parameters.

**Results**

For MAX0, AMAX1, DMAX1, QMAX1, IMAX0, JMAX0, and KMAX0, the result type is the same as the arguments. For MAX1, IMAX1, JMAX1, and KMAX1, the result type is integer. For AMAX0, AIMAX0, AJMAX0, and AKMAX0, the result type is real. The value of the result is that of the largest argument.

<table>

</tbody>
</table>

1 These specific functions cannot be passed as actual arguments.
2 Or JMAX0.
3 Or AJMAX0. AMAX0 is the same as REAL (MAX).
In Fortran 95/90, AMAX0 and MAX1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.

Or JMAX1.MAX1 is the same as INT(MAX).

The setting of compiler options specifying integer size can affect MAX1.

The setting of compiler options specifying real size can affect AMAX1.

Example

MAX (2.0, -8.0, 6.0) has the value 6.0.

MAX (14, 32, -50) has the value 32.

The following shows another example:

```fortran
INTEGER m1, m2
REAL r1, r2
m1 = MAX(5, 6, 7) ! returns 7
m2 = MAX1(5.7, 3.2, -8.3) ! returns 5
r1 = AMAX0(5, 6, 7) ! returns 7.0
r2 = AMAX1(6.4, -12.2, 4.9) ! returns 6.4
```

See Also

- M to N
- MIN

**MAXEXPONENT**

*Inquiry Intrinsic Function (Generic):* Returns the maximum exponent in the model representing the same type and kind parameters as the argument.

**Syntax**

```fortran
result = MAXEXPONENT (x)
```

*x* (Input) Must be of type real; it can be scalar or array valued.
Results

The result is a scalar of type default integer. The result has the value $e_{\text{max}}$, as defined in Model for Real Data.

Example

```fortran
REAL(4) x
INTEGER i
i = MAXEXPONENT(x) ! returns 128.
```

See Also

- M to N
- MINEXPONENT

MAXLOC

**Transformational Intrinsic Function (Generic):**

Returns the location of the maximum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax

```fortran
result = MAXLOC (array [, dim] [, mask] [, kind])
```

- `array` (Input) Must be an array of type integer or real.
- `dim` (Input; optional) Must be a scalar integer with a value in the range 1 to $n$, where $n$ is the rank of `array`. This argument is a Fortran 95 feature.
- `mask` (Input; optional) Must be a logical array that is conformable with `array`.
- `kind` (Input; optional) Must be a scalar integer initialization expression.

Results

The result is an array of type integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rules apply if `dim` is omitted:
• The array result has rank one and a size equal to the rank of \textit{array}.

• If \texttt{MAXLOC(array)} is specified, the elements in the array result form the subscript of the location of the element with the maximum value in \texttt{array}.

  The $i$th subscript returned lies in the range 1 to $e_i$, where $e_i$ is the extent of the $i$th dimension of \texttt{array}.

• If \texttt{MAXLOC(array, MASK= mask)} is specified, the elements in the array result form the subscript of the location of the element with the maximum value corresponding to the condition specified by \texttt{mask}.

The following rules apply if \texttt{dim} is specified:

• The array result has a rank that is one less than \texttt{array}, and shape $(d_1, d_2, \ldots, d_{\text{dim}-1}$, $d_{\text{dim}+1}, \ldots, d_n)$, where $(d_1, d_2, \ldots, d_n)$ is the shape of \texttt{array}.

• If \texttt{array} has rank one, \texttt{MAXLOC(array, dim[, mask])} has a value equal to that of \texttt{MAXLOC(array[, MASK= mask])}. Otherwise, the value of element $(s_1, s_2, \ldots, s_{\text{dim}-1}, s_{\text{dim}+1}, \ldots, s_n)$ of \texttt{MAXLOC(array, dim[, mask])} is equal to \texttt{MAXLOC(array(s_1, s_2, \ldots, s_{\text{dim}-1}; s_{\text{dim}+1}, \ldots, s_n)[, MASK = mask(s_1, s_2, \ldots, s_{\text{dim}-1}; s_{\text{dim}+1}, \ldots, s_n)])}.

If more than one element has maximum value, the element whose subscripts are returned is the first such element, taken in array element order. If \texttt{array} has size zero, or every element of \texttt{mask} has the value \texttt{.FALSE.}, the value of the result is controlled by compiler option \texttt{assume [no]old_maxminloc}, which can set the result to either 1 or 0.

The setting of compiler options specifying integer size can affect this function.

\textbf{Example}

The value of \texttt{MAXLOC((/3, 7, 4, 7/))} is (2), which is the subscript of the location of the first occurrence of the maximum value in the rank-one array.

A is the array

\begin{verbatim}
  [ 4  0  -3  2 ]
  [ 3  1  -2  6 ]
  [ -1 -4   5  -5 ].
\end{verbatim}

\texttt{MAXLOC (A, MASK=A .LT. 5)} has the value (1, 1) because these are the subscripts of the location of the maximum value (4) that is less than 5.
MAXLOC (A, DIM=1) has the value (1, 2, 3, 2). 1 is the subscript of the location of the maximum value (4) in column 1; 2 is the subscript of the location of the maximum value (1) in column 2; and so forth.

MAXLOC (A, DIM=2) has the value (1, 4, 3). 1 is the subscript of the location of the maximum value in row 1; 4 is the subscript of the location of the maximum value in row 2; and so forth.
The following shows another example:

```fortran
INTEGER i, max
INTEGER i, max1(1)
INTEGER array(3, 3)
INTEGER, ALLOCATABLE :: AR1(:)

! put values in array
array = RESHAPE((/7, 9, -1, -2, 5, 0, 3, 6, 9/), (/3, 3/))
! array is 7 -2 3
! 9 5 6
! -1 0 9

i = SIZE(SHAPE(array)) ! Get number of dimensions
! in array
ALLOCATE ( AR1(i)) ! Allocate AR1 to number
! of dimensions in array

AR1 = MAXLOC(array, MASK = array .LT. 7) ! Get
! the location (subscripts) of
! largest element less than 7
! in array

! MASK = array .LT. 7 creates a mask array the same
! size and shape as array whose elements are .TRUE. if
! the corresponding element in array is less than 7,
! and .FALSE. if it is not. This mask causes MAXLOC to
! return the index of the element in array with the
! greatest value less than 7.
!
! array is 7 -2 3 and MASK = array .LT. 7 is F T T
! 9 5 6 F T T
```
and $AR1 = \text{MAXLOC}(\text{array}, \text{MASK} = \text{array} \ .LT. 7)$ returns
$(2, 3)$, the location of the element with value 6

$maxl = \text{MAXLOC}((/1, 4, 3, 4/)) \quad \text{! returns 2, the first}
\quad \text{! occurrence of maximum}

\textit{See Also}
• M to N
• MAXVAL
• MINLOC
• MINVAL

\textbf{MAXVAL}

\textit{Transformational Intrinsic Function (Generic):}
Returns the maximum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

\textbf{Syntax}

\begin{verbatim}
result = MAXVAL(array[,dim] [,mask])
\end{verbatim}

- \textit{array} (Input) Must be an array of type integer or real.
- \textit{dim} (Input; optional) Must be a scalar integer expression with a value in the range 1 to \textit{n}, where \textit{n} is the rank of \textit{array}.
- \textit{mask} (Input; optional) Must be a logical array that is conformable with \textit{array}.

\textbf{Results}

The result is an array or a scalar of the same data type as \textit{array}.

The result is a scalar if \textit{dim} is omitted or \textit{array} has rank one.

The following rules apply if \textit{dim} is omitted:

- If \text{MAXVAL}(\textit{array}) is specified, the result has a value equal to the maximum value of all the elements in \textit{array}. 

3002
• If MAXVAL( array, MASK= mask) is specified, the result has a value equal to the maximum value of the elements in array corresponding to the condition specified by mask.

The following rules apply if dim is specified:

• An array result has a rank that is one less than array, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of array.

• If array has rank one, MAXVAL( array, dim[, mask]) has a value equal to that of MAXVAL( array[, MASK = mask]). Otherwise, the value of element (s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n) of MAXVAL( array, dim, [, mask]) is equal to MAXVAL( array(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) [, MASK = mask(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)]).

If array has size zero or if there are no true elements in mask, the result (if dim is omitted), or each element in the result array (if dim is specified), has the value of the negative number of the largest magnitude supported by the processor for numbers of the type and kind parameters of array.

Example

The value of MAXVAL ((/2, 3, 4/)) is 4 because that is the maximum value in the rank-one array.

MAXVAL (B, MASK=B .LT. 0.0) finds the maximum value of the negative elements of B.

C is the array

[ 2 3 4 ]
[ 5 6 7 ].

MAXVAL (C, DIM=1) has the value (5, 6, 7). 5 is the maximum value in column 1; 6 is the maximum value in column 2; and so forth.

MAXVAL (C, DIM=2) has the value (4, 7). 4 is the maximum value in row 1 and 7 is the maximum value in row 2.
The following shows another example:

```fortran
INTEGER array(2,3), i(2), max
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/),(/2, 3/))
! array is 1 5 3
!   4 2 6
i = SHAPE(array) ! i = [2 3]
ALLOCATE (AR1(i(2))) ! dimension AR1 to the number of
! elements in dimension 2
!   (a column) of array
ALLOCATE (AR2(i(1))) ! dimension AR2 to the number of
! elements in dimension 1
!   (a row) of array
max = MAXVAL(array, MASK = array .LT. 4) ! returns 3
AR1 = MAXVAL(array, DIM = 1) ! returns [ 4 5 6 ]
AR2 = MAXVAL(array, DIM = 2) ! returns [ 5 6 ]
END
```

**MBCharLen (W*32, W*64)**

*NLS Function:* Returns the length, in bytes, of the first character in a multibyte-character string.

**Module**

```fortran
USE IFNLS
```
Syntax

result = MBCharLen (string)

string (Input) Character*(*). String containing the character whose length is to be determined. Can contain multibyte characters.

Results

The result type is INTEGER(4). The result is the number of bytes in the first character contained in string. The function returns 0 if string has no characters (is length 0).

MBCharLen does not test for multibyte character validity.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also

• MBLead
• MBLen
• MBLen_Trim

MBConvertMBToUnicode (W*32, W*64)

NLS Function: Converts a multibyte-character string from the current codepage to a Unicode string.

Module

USE IFNLS

Syntax

result = MBConvertMBToUnicode (mbstr, unicodestr [,flags])

mbstr (Input) Character*(*). Multibyte codepage string to be converted.

unicodestr (Output) INTEGER(2). Array of integers that is the translation of the input string into Unicode.
flags (Input; optional) INTEGER(4). If specified, modifies the string conversion. If flags is omitted, the value NLS$Precomposed is used. Available values (defined in IFNLS.F90) are:

- NLS$Precomposed - Use precomposed characters always. (default)
- NLS$Composite - Use composite wide characters always.
- NLS$UseGlyphChars - Use glyph characters instead of control characters.
- NLS$ErrorOnInvalidChars - Returns -1 if an invalid input character is encountered.

The flags NLS$Precomposed and NLS$Composite are mutually exclusive. You can combine NLS$UseGlyphChars with either NLS$Precomposed or NLS$Composite using an inclusive OR (IOR or OR).

**Results**

The result type is INTEGER(4). If no error occurs, the result is the number of bytes written to uncodestr (bytes are counted, not characters), or the number of bytes required to hold the output string if uncodestr has zero size. If the uncodestr array is bigger than needed to hold the translation, the extra elements are set to space characters. If uncodestr has zero size, the function returns the number of bytes required to hold the translation and nothing is written to uncodestr.

If an error occurs, one of the following negative values is returned:

- NLS$ErrorInsufficientBuffer - The uncodestr argument is too small, but not zero size so that the needed number of bytes would be returned.
- NLS$ErrorInvalidFlags - The flags argument has an illegal value.
- NLS$ErrorInvalidCharacter - A character with no Unicode translation was encountered in mbstr. This error can occur only if the NLS$InvalidCharsError flag was used in flags.

**NOTE.** By default, or if flags is set to NLS$Precomposed, the function MBConvertMBToUnicode attempts to translate the multibyte codepage string to a precomposed Unicode string. If a precomposed form does not exist, the function attempts to translate the codepage string to a composite form.
Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• M to N
• MBConvertUnicodeToMB

MBConvertUnicodeToMB (W*32, W*64)

NLS Function: Converts a Unicode string to a multibyte-character string from the current codepage.

Module
USE IFNLS

Syntax
result = MBConvertUnicodeToMB (unicodestr, mbstr[,flags])

unicodestr (Input) INTEGER(2). Array of integers holding the Unicode string to be translated.

mbstr (Output) Character*(*). Translation of Unicode string into multibyte character string from the current codepage.

flags (Input; optional) INTEGER(4). If specified, argument to modify the string conversion. If flags is omitted, no extra checking of the conversion takes place. Available values (defined in IFNLS.F90) are:

• NLS$CompositeCheck - Convert composite characters to precomposed.
• NLS$SepChars - Generate separate characters.
• NLS$DiscardDns - Discard nonspace characters.
• NLS$DefaultChars - Replace exceptions with default character.

The last three flags (NLS$SepChars, NLS$DiscardDns, and NLS$DefaultChars) are mutually exclusive and can be used only if NLS$CompositeCheck is set, in which case one (and only one) of them is combined with NLS$CompositeCheck using an inclusive
OR (IOR or OR). These flags determine what translation to make when there is no precomposed mapping for a base character/nonspace character combination in the Unicode wide character string. The default (IOR(NLS$CompositeCheck, NLS$SepChars)) is to generate separate characters.

**Results**

The result type is INTEGER(4). If no error occurs, returns the number of bytes written to mbstr (bytes are counted, not characters), or the number of bytes required to hold the output string if mbstr has zero length. If mbstr is longer than the translation, it is blank-padded. If mbstr is zero length, the function returns the number of bytes required to hold the translation and nothing is written to mbstr.

If an error occurs, one of the following negative values is returned:

- NLS$ErrorInsufficentBuffer - The mbstr argument is too small, but not zero length so that the needed number of bytes is returned.
- NLS$ErrorInvalidFlags - The flags argument has an illegal value.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- M to N
- MBConvertMBToUnicode

**MBCurMax (W*32, W*64)**

*NLS Function: Returns the longest possible multibyte character length, in bytes, for the current codepage.*

**Module**

USE IFNLS

**Syntax**

```fortran
result = MBCurMax() 
```
Results
The result type is INTEGER(4). The result is the longest possible multibyte character, in bytes, for the current codepage.

The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• M to N
• MBCharLen

Building Applications: MBCS Inquiry Routines

MBINCHARQQ (W*32, W*64)

NLS Function: Performs the same function as INCHARQQ except that it can read a single multibyte character at once, and it returns the number of bytes read as well as the character.

Module
USE IFNLS

Syntax
result = MBINCHARQQ (string)

string (Output) CHARACTER(MBLenMax). String containing the read characters, padded with blanks up to the length MBLenMax. The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

Results
The result type is INTEGER(4). The result is the number of characters read.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also

- M to N
- INCHARQQ
- MBCurMax
- MBCharLen
- MBLead

MBINDEX (W*32, W*64)

*NLS Function:* Performs the same function as INDEX except that the strings manipulated can contain multibyte characters.

**Module**

USE IFNLS

**Syntax**

```
result = MBINDEX (string, substring [, back])
```

**string** (Input) CHARACTER*(*)

String to be searched for the presence of substring. Can contain multibyte characters.

**substring** (Input) CHARACTER*(*)

Substring whose position within string is to be determined. Can contain multibyte characters.

**back** (Input; optional) LOGICAL(4)

If specified, determines direction of the search. If back is .FALSE. or is omitted, the search starts at the beginning of string and moves toward the end. If back is .TRUE., the search starts end of string and moves toward the beginning.

**Results**

The result type is INTEGER(4). If back is omitted or is .FALSE., it returns the leftmost position in string that contains the start of substring. If back is .TRUE., it returns the rightmost position in string that contains the start of substring. If string does not contain substring, it returns 0. If substring occurs more than once, it returns the starting position of the first occurrence (“first” is determined by the presence and value of back).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**MBJISToJMS, MBJMSToJIS (W*32, W*64)**

**NLS Functions:** Converts Japan Industry Standard (JIS) characters to Microsoft Kanji (JMS) characters, or converts JMS characters to JIS characters.

**Module**

USE IFNLS

**Syntax**

\[
\text{result} = \text{MBJISToJMS (char)}
\]

\[
\text{result} = \text{MBJISToJIS (char)}
\]

**char**

(Input) CHARACTER(2). JIS or JMS character to be converted.
A JIS character is converted only if the lead and trail bytes are in
the hexadecimal range 21 through 7E.
A JMS character is converted only if the lead byte is in the
hexadecimal range 81 through 9F or E0 through FC, and the trail
byte is in the hexadecimal range 40 through 7E or 80 through FC.

**Results**

The result type is character with length 2. MBJISToJMS returns a Microsoft Kanji (Shift JIS or JMS) character. MBJMSToJIS returns a Japan Industry Standard (JIS) character.

Only computers with Japanese installed as one of the available languages can use the MBJISToJMS and MBJMSToJIS conversion functions.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- M to N
Building Applications: MBCS Conversion Routines

**MBLead (W*32, W*64)**

*NLS Function: Determines whether a given character is the lead (first) byte of a multibyte character sequence.*

**Module**

USE IFNLS

**Syntax**

\[
\text{result} = \text{MBLead} \ (\text{char})
\]

(char) (Input) CHARACTER(1). Character to be tested for lead status.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if char is the first character of a multibyte character sequence; otherwise, .FALSE..

MBLead only works stepping forward through a whole multibyte character string. For example:

```fortran
DO i = 1, LEN(str) ! LEN returns the number of bytes, not the number of characters in str
    WRITE(*, 100) MBLead (str(i:i))
END DO
```

100 FORMAT (L2, ")

MBLead is passed only one character at a time and must start on a lead byte and step through a string to establish context for the character. MBLead does not correctly identify a nonlead byte if it is passed only the second byte of a multibyte character because the status of lead byte or trail byte depends on context.
The function MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context. So, MBStrLead can be much slower than MBLead (up to $n$ times slower, where $n$ is the length of the string).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**
- M to N
- MBStrLead
- MBCharLen

*Building Applications*: MBCS Inquiry Routines

**MBLen (W*32, W*64)**

*NLS Function*: Returns the number of characters in a multibyte-character string, including trailing blanks.

**Module**

USE IFNLS

**Syntax**

result = MBLen (string)

*string* (Input) CHARACTER*(*)). String whose characters are to be counted. Can contain multibyte characters.

**Results**

The result type is INTEGER(4). The result is the number of characters in *string*.

MBLen recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also

- M to N
- MBLen_Trim
- MBStrLead

*Building Applications: MBCS Inquiry Routines*

**MBLen_Trim (W*32, W*64)**

*NLS Function: Returns the number of characters in a multibyte-character string, not including trailing blanks.*

**Module**

USE IFNLS

**Syntax**

\[
\text{result} = \text{MBLen\_Trim} (\text{string})
\]

\[\text{string} \quad \text{(Input) Character*(*). String whose characters are to be counted. Can contain multibyte characters.}\]

**Results**

The result type is INTEGER(4). The result is the number of characters in \text{string} minus any trailing blanks (blanks are bytes containing character 32 (hex 20) in the ASCII collating sequence).

MBLen_Trim recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- M to N
- MBLen
- MBStrLead

*Building Applications: MBCS Inquiry Routines*
**MGLGE, MGLGT, MGLLE, MGLLT, MGLEQ, MGLNE (W*32, W*64)**

**NLS Functions:** Perform the same functions as LGE, LGT, LLE, LLT and the logical operators .EQ. and .NE. except that the strings being compared can include multibyte characters, and optional flags can modify the comparison.

---

**Module**

USE IFNLS

**Syntax**

```fortran
result = MGLGE (string_a,string_b, [ flags])
result = MGLGT (string_a,string_b, [ flags])
result = MGLLE (string_a,string_b, [ flags])
result = MGLLT (string_a,string_b, [ flags])
result = MGLEQ (string_a,string_b, [ flags])
result = MGLNE (string_a,string_b, [ flags])
```

- `string_a, string_b` (Input) Character*(*). Strings to be compared. Can contain multibyte characters.
- `flags` (Input; optional) INTEGER(4). If specified, determines which character traits to use or ignore when comparing strings. You can combine several flags using an inclusive OR (IOR or OR). There are no illegal combinations of flags, and the functions may be used without flags, in which case all flag options are turned off. The available values (defined in `IFNLS.F90`) are:
  - NLS$MB_IgnoreCase - Ignore case.
  - NLS$MB_IgnoreNonspace - Ignore nonspacing characters (this flag removes Japanese accent characters if they exist).
  - NLS$MB_IgnoreSymbols - Ignore symbols.
  - NLS$MB_IgnoreKanaType - Do not differentiate between Japanese Hiragana and Katakana characters (corresponding Hiragana and Katakana characters will compare as equal).
• NLS$MB_IgnoreWidth - Do not differentiate between a single-byte character and the same character as a double byte.
• NLS$MB_StringSort - Sort all symbols at the beginning, including the apostrophe and hyphen (see the Note below).

Results

The result type is LOGICAL(4). Comparisons are made using the current locale, not the current codepage. The codepage used is the default for the language/country combination of the current locale.

The results of these functions are as follows:

• MBLGE returns .TRUE. if the strings are equal or string_a comes last in the collating sequence; otherwise, .FALSE..
• MBLGT returns .TRUE. if string_a comes last in the collating sequence; otherwise, .FALSE..
• MBLLE returns .TRUE. if the strings are equal or string_a comes first in the collating sequence; otherwise, .FALSE..
• MBLLT returns .TRUE. if string_a comes first in the collating sequence; otherwise, .FALSE..
• MBLEQ returns .TRUE. if the strings are equal in the collating sequence; otherwise, .FALSE..
• MBLNE returns .TRUE. if the strings are not equal in the collating sequence; otherwise, .FALSE..

If the two strings are of different lengths, they are compared up to the length of the shortest one. If they are equal to that point, then the return value indicates that the longer string is greater.

If flags is invalid, the functions return .FALSE..

If the strings supplied contain Arabic Kashidas, the Kashidas are ignored during the comparison. Therefore, if the two strings are identical except for Kashidas within the strings, the functions return a value indicating they are "equal" in the collation sense, though not necessarily identical.

NOTE. When not using the NLS$MB_StringSort flag, the hyphen and apostrophe are special symbols and are treated differently than others. This is to ensure that words like coop and co-op stay together within a list. All symbols, except the hyphen and apostrophe, sort before any other alphanumeric character. If you specify the NLS$MB_StringSort flag, hyphen and apostrophe sort at the beginning also.

MBNext (W*32, W*64)

**NLS Function:** Returns the position of the first lead byte or single-byte character immediately following the given position in a multibyte-character string.

Module

USE IFNLS

Syntax

```
result = MBNext (string, position)
```

- **string** (Input) Character*(*). String to be searched for the first lead byte or single-byte character after the current position. Can contain multibyte characters.
- **position** (Input) INTEGER(4). Position in string to search from. Must be the position of a lead byte or a single-byte character. Cannot be the position of a trail (second) byte of a multibyte character.

Results

The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in string immediately following the position given in position, or 0 if no following first byte is found in string.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Building Applications: MBCS Inquiry Routines

MBPrev (W*32, W*64)

NLS Function: Returns the position of the first lead byte or single-byte character immediately preceding the given string position in a multibyte-character string.

Module
USE IFNLS

Syntax
result = MBPrev (string, position)

string (Input) Character*(*). String to be searched for the first lead byte or single-byte character before the current position. Can contain multibyte characters.

position (Input) INTEGER(4). Position in string to search from. Must be the position of a lead byte or single-byte character. Cannot be the position of the trail (second) byte of a multibyte character.

Results
The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in string immediately preceding the position given in position, or 0 if no preceding first byte is found in string.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**MBSCAN (W*32, W*64)**

**NLS Function:** Performs the same function as SCAN except that the strings manipulated can contain multibyte characters.

**Module**

USE IFNLS

**Syntax**

\[
\text{result} = \text{MBSCAN} (\text{string}, \text{set}[, \text{back}])
\]

- **string** (Input) Character*(*) String to be searched for the presence of any character in **set**.
- **set** (Input) Character*(*) Characters to search for.
- **back** (Input; optional) LOGICAL(4). If specified, determines direction of the search. If **back** is .FALSE. or is omitted, the search starts at the beginning of **string** and moves toward the end. If **back** is .TRUE., the search starts end of **string** and moves toward the beginning.

**Results**

The result type is INTEGER(4). If **back** is .FALSE. or is omitted, it returns the position of the leftmost character in **string** that is in **set**. If **back** is .TRUE., it returns the rightmost character in **string** that is in **set**. If no characters in **string** are in **set**, it returns 0.

**Compatibility**

- MBVERIFY
MBStrLead (W*32, W*64)

NLS Function: Performs a context-sensitive test to determine whether a given character byte in a string is a multibyte-character lead byte.

Module
USE IFNLS

Syntax
result = MBStrLead (string, position)

string (Input) Character*(*) String containing the character byte to be tested for lead status.
position (Input) INTEGER(4). Position in string of the character byte in the string to be tested.

Results
The result type is LOGICAL(4). The result is .TRUE. if the character byte in position of string is a lead byte; otherwise, .FALSE..

MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context.

MBLead is passed only one character at a time and must start on a lead byte and step through a string one character at a time to establish context for the character. So, MBStrLead can be much slower than MBLead (up to n times slower, where n is the length of the string).

Compatibility

Building Applications: MBCS Inquiry Routines
**MBVERIFY (W*32, W*64)**

**NLS Function:** Performs the same function as VERIFY except that the strings manipulated can contain multibyte characters.

**Module**

USE IFNLS

**Syntax**

\[
\text{result} = \text{MBVERIFY} \left( \text{string}, \text{set}[, \text{back}] \right)
\]

- **string** (Input) Character*(*). String to be searched for presence of any character not in **set**.
- **set** (Input) Character*(*). Set of characters tested to verify that it includes all the characters in **string**.
- **back** (Input; optional) LOGICAL(4). If specified, determines direction of the search. If **back** is .FALSE. or is omitted, the search starts at the beginning of **string** and moves toward the end. If **back** is .TRUE., the search starts end of **string** and moves toward the beginning.

**Results**

The result type is INTEGER(4). If **back** is .FALSE. or is omitted, it returns the position of the leftmost character in **string** that is not in **set**. If **back** is .TRUE., it returns the rightmost character in **string** that is not in **set**. If all the characters in **string** are in **set**, it returns 0.

MCLOCK

_Inquiry Intrinsic Function (Specific): Returns time accounting for a program._

Syntax

\[
\text{result} = \text{MCLOCK}( )
\]

Results

The result type is INTEGER(4). The result is the sum (in units of microseconds) of the current process’s user time and the user and system time of all its child processes.

MEMORYTOUCH (i64 only)

_General Compiler Directive: Ensures that a specific memory location is updated dynamically._

Syntax

\[
c\text{DEC$ MEMORYTOUCH} (\text{array}[, \text{schedule-type} [\{\text{chunk-size}\}]] [,\text{init-type}])
\]

\[
c\]

Is a c, C, I, or *. (See Syntax Rules for Compiler Directives.)

\[
\text{array}
\]

Is an array of type INTEGER(4), INTEGER(8), REAL(4) or REAL(8).

\[
\text{schedule-type}
\]

Is STATIC, GUIDED, RUNTIME or DYNAMIC, whichever is consistent with the OpenMP conforming processing of the subsequent parallel loops.

\[
\text{chunk-size}
\]

Is an integer expression.

\[
\text{init-type}
\]

Is LOAD or STORE. If _init-type_ is LOAD, the compiler generates an OpenMP loop which fetches elements of _array_ into a temporary variable. If _init-type_ is STORE, the compiler generates an OpenMP loop which sets elements of _array_ to zero.

The MEMORYTOUCH directive ensures that a specific memory location is updated dynamically. This prevents the possibility of multiple, simultaneous writing threads.

This directive supports correctly distributed memory initialization and NUMA pre-fetching.

To use this directive, OpenMP must be enabled.
Example

c$DEC memorytouch (ARRAY_A)
c$DEC memorytouch (ARRAY_A, LOAD)
c$DEC memorytouch (ARRAY_A, STATIC {load+jf(3)})
c$DEC memorytouch (ARRAY_A, GUIDED (20), STORE)

See Also

- M to N
- General Compiler Directives

MEMREF_CONTROL (i64 only)

**General Compiler Directive:** Lets you provide cache hints on prefetches, loads, and stores.

Syntax

```
c$DEC$ MEMREF_CONTROL address1[: locality[: latency]] [,address2...]
```

c Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

address1, address2 Is a memory reference. You must specify at least one address.

locality Is an optional scalar integer initialization expression with the value 1, 2, 3, or 4. To use this argument, you must also specify address. This argument specifies the cache level at which this data has temporal locality, that is, where the data should be kept for future accesses. This will determine the load/store hint (or prefetch hint) to be used for this reference. The value can be one of the following:

```
FOR_K_LOCALITY_L1 = 1
FOR_K_LOCALITY_L2 = 2
FOR_K_LOCALITY_L3 = 3
FOR_K_LOCALITY_MEM = 4
```

latency Is an optional scalar integer initialization expression with the value 1, 2, 3, or 4. To use this argument, you must also specify address and locality.
This argument specifies the most appropriate latency value to be used for a load (or the latency that has to be overlapped if a prefetch is issued for this address). The value can be one of the following:

\[
\begin{align*}
\text{FOR}_K\text{\_LATENCY\_L1} & = 1 \\
\text{FOR}_K\text{\_LATENCY\_L2} & = 2 \\
\text{FOR}_K\text{\_LATENCY\_L3} & = 3 \\
\text{FOR}_K\text{\_LATENCY\_MEM} & = 4
\end{align*}
\]

See Also
- M to N
- PREFETCH and NOPREFETCH

**MERGE**

*Elemental Intrinsic Function (Generic): Selects between two values or between corresponding elements in two arrays, according to the condition specified by a logical mask.*

**Syntax**

\[
\text{result} = \text{MERGE}\left(\text{tsource}, \text{fsource}, \text{mask}\right)
\]

*Input* May be of any data type.

*tsource* (Input) Must be of the same type and type parameters as tsource.

*fsource* (Input) Must be of type logical.

*mask* (Input) Must be of type logical.

**Results**

The result type is the same as tsource. The value of mask determines whether the result value is taken from tsource (if mask is true) or fsource (if mask is false).

**Example**

For MERGE (1.0, 0.0, R < 0), R = -3 has the value 1.0, and R = 7 has the value 0.0.
TSOURCE is the array
\[
\begin{bmatrix}
1 & 3 & 5 \\
2 & 4 & 6
\end{bmatrix},
\]

FSOURCE is the array
\[
\begin{bmatrix}
8 & 9 & 0 \\
1 & 2 & 3
\end{bmatrix},
\]

and MASK is the array
\[
\begin{bmatrix}
F & T & T \\
T & T & F
\end{bmatrix}.
\]

MERGE (TSOURCE, FSOURCE, MASK) produces the result:
\[
\begin{bmatrix}
8 & 3 & 5 \\
2 & 4 & 3
\end{bmatrix}.
\]

The following shows another example:

```
INTEGER tsource(2, 3), fsource(2, 3), AR1 (2, 3)
LOGICAL mask(2, 3)
tsource = RESHAPE((/1, 4, 2, 5, 3, 6/),(/2, 3/))
fsource = RESHAPE((/7, 0, 8, -1, 9, -2/), (/2, 3/))
mask = RESHAPE((/.TRUE., .FALSE., .FALSE., .TRUE., .FALSE., .FALSE./), (/2,3/))
! tsource is 1 2 3 , fsource is 7 8 9 , mask is T F T
! 4 5 6 0 -1 -2 F T F
AR1 = MERGE(tsource, fsource, mask) ! returns 1 8 3
! 0 5 -2
```

END
MESSAGE

General Compiler Directive: Specifies a character string to be sent to the standard output device during the first compiler pass; this aids debugging.

Syntax

cDEC$ MESSAGE: string

c
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

string
Is a character constant specifying a message.

Example

!DEC$ MESSAGE:'Compiling Sound Speed Equations'

See Also
• M to N
• General Compiler Directives

MESSAGEBOXQQ (W*32, W*64)

QuickWin Function: Displays a message box in a QuickWin window.

Module
USE IFQWIN

Syntax

result = MESSAGEBOXQQ (msg, caption, mtype)

msg
(Input) Character*(*) Null-terminated C string. Message the box displays.

caption
(Input) Character*(*) Null-terminated C string. Caption that appears in the title bar.
**mtype**

(Input) INTEGER(4). Symbolic constant that determines the objects (buttons and icons) and properties of the message box. You can combine several constants (defined in IFQWIN.F90) using an inclusive OR (IOR or OR). The symbolic constants and their associated objects or properties are as follows:

- MB$ABORTRETRYIGNORE - The Abort, Retry, and Ignore buttons.
- MB$DEFBUTTON1 - The first button is the default.
- MB$DEFBUTTON2 - The second button is the default.
- MB$DEFBUTTON3 - The third button is the default.
- MB$ICONASTERISK, MB$ICONINFORMATION - Lowercase i in blue circle icon.
- MB$ICONEXCLAMATION - The exclamation-mark icon.
- MB$ICONHAND, MB$ICONSTOP - The stop-sign icon.
- MB$ICONQUESTION - The question-mark icon.
- MB$OK - The OK button.
- MB$OKCANCEL - The OK and Cancel buttons.
- MB$RETRYCANCEL - The Retry and Cancel buttons.
- MB$SYSTEMMODAL - Box is system-modal: all applications are suspended until the user responds.
- MB$YESNO - The Yes and No buttons.
- MB$YESNOCANCEL - The Yes, No, and Cancel buttons.

**Results**

The result type is INTEGER(4). The result is zero if memory is not sufficient for displaying the message box. Otherwise, the result is one of the following values, indicating the user’s response to the message box:

- MB$IDABORT - The Abort button was pressed.
- MB$IDCANCEL - The Cancel button was pressed.
- MB$IDIGNORE - The Ignore button was pressed.
- MB$IDNO - The No button was pressed.
• MB$IDOK - The OK button was pressed.
• MB$IDRETRY - The Retry button was pressed.
• MB$IDYES - The Yes button was pressed.

**Compatibility**

QUICKWIN GRAPHICS LIB

**Example**

! Build as QuickWin app
USE IFQWIN
message = MESSAGEBOXQQ('Do you want to continue?'C, &
'Matrix'C, &
MB$ICONQUESTION.OR.MB$YESNO.OR.MB$DEFBUTTON1)

END

**MIN**

*Elemental Intrinsic Function (Generic):*

*Returns the minimum value of the arguments.*

**Syntax**

result = MIN (a1,a2[,a3...])

*a1, a2, a3*  
(Input) All must have the same type (integer or real) and kind parameters.
Results

For MIN0, AMIN1, DMIN1, QMIN1, IMIN0, JMIN0, and KMIN0, the result type is the same as the arguments. For MIN1, IMIN1, JMIN1, and KMIN1, the result type is integer. For AMIN0, AIMIN0, AJMIN0, and AKMIN0, the result type is real. The value of the result is that of the smallest argument.

<table>

<td>REAL(16)</td>
</tr>
</tbody>
</table>

1These specific functions cannot be passed as actual arguments.

2Or JMIN0.

3Or AJMIN0. AMIN0 is the same as REAL (MIN).
In Fortran 95/90, AMIN0 and MIN1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.

Or JMIN1.MIN1 is the same as INT (MIN).

The setting of compiler options specifying integer size can affect MIN1.

The setting of compiler options specifying real size can affect AMIN1.

Example

MIN (2.0, -8.0, 6.0) has the value -8.0.

MIN (14, 32, -50) has the value -50.

The following shows another example:

```fortran
INTEGER m1, m2
REAL r1, r2
m1 = MIN (5, 6, 7) ! returns 5
m2 = MIN1 (-5.7, 1.23, -3.8) ! returns -5
r1 = AMIN0 (-5, -6, -7) ! returns -7.0
r2 = AMIN1 (-5.7, 1.23, -3.8) ! returns -5.7
```

See Also

- M to N
- MAX

MINEXponent

**Inquiry Intrinsic Function (Generic)**: Returns the minimum exponent in the model representing the same type and kind parameters as the argument.

**Syntax**

```fortran
result = MINEXPONENT (x)
```

x (Input) must be of type real; it can be scalar or array valued.
**Results**

The result is a scalar of type default integer. The result has the value $e_{\text{min}}$, as defined in Model for Real Data.

**Example**

If X is of type REAL(4), MINEXPONENT (X) has the value -125.

The following shows another example:

```fortran
REAL(8) r1 ! DOUBLE PRECISION REAL
INTEGER i
i = MINEXPONENT (r1) ! returns -1021.
```

**See Also**
- M to N
- MAXEXPONENT

**MINLOC**

*Transformational Intrinsic Function (Generic):*
Returns the location of the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

**Syntax**

```fortran
result = MINLOC (array [, dim] [, mask] [, kind])
```

- `array` (Input) Must be an array of type integer or real.
- `dim` (Input; optional) Must be a scalar integer with a value in the range 1 to n, where n is the rank of `array`. This argument is a Fortran 95 feature.
- `mask` (Input; optional) Must be a logical array that is conformable with `array`.
- `kind` (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result is an array of type integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.
The following rules apply if \( \text{dim} \) is omitted:

- The array result has rank one and a size equal to the rank of \( \text{array} \).

- If MINLOC(\( \text{array} \)) is specified, the elements in the array result form the subscript of the location of the element with the minimum value in \( \text{array} \).
  
  The \( i \)th subscript returned lies in the range 1 to \( e_i \), where \( e_i \) is the extent of the \( i \)th dimension of \( \text{array} \).

- If MINLOC(\( \text{array} \), \( \text{MASK}=\text{mask} \)) is specified, the elements in the array result form the subscript of the location of the element with the minimum value corresponding to the condition specified by \( \text{mask} \).

The following rules apply if \( \text{dim} \) is specified:

- The array result has a rank that is one less than \( \text{array} \), and shape \((d_1, d_2, ..., d_{\text{dim}-1}, d_{\text{dim}+1}, ..., d_n)\), where \((d_1, d_2, ..., d_n)\) is the shape of \( \text{array} \).

- If \( \text{array} \) has rank one, MINLOC(\( \text{array}, \text{dim}[, \text{mask}] \)) has a value equal to that of MINLOC(\( \text{array}[,, \text{MASK}=\text{mask}] \)). Otherwise, the value of element \((s_1, s_2, ..., s_{\text{dim}-1}, s_{\text{dim}+1}, ..., s_n)\) of MINLOC(\( \text{array}, \text{dim}[, \text{mask}] \)) is equal to MINLOC(\( \text{array}(s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n) [, \text{MASK}=\text{mask}(s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n)] \)).

If more than one element has minimum value, the element whose subscripts are returned is the first such element, taken in array element order. If \( \text{array} \) has size zero, or every element of \( \text{mask} \) has the value \( \text{FALSE} \), the value of the result is controlled by compiler option \( \text{assume [no]old_maxminloc} \), which can set the result to either 1 or 0.

The setting of compiler options specifying integer size can affect this function.

**Example**

The value of MINLOC((/3, 1, 4, 1/)) is (2), which is the subscript of the location of the first occurrence of the minimum value in the rank-one array.

\( A \) is the array

\[
\begin{bmatrix}
4 & 0 & -3 & 2 \\
3 & 1 & -2 & 6 \\
-1 & -4 & 5 & -5
\end{bmatrix}
\]

MINLOC(\( A, \text{MASK}=A \cdot \text{GT.} \cdot -5 \)) has the value (3, 2) because these are the subscripts of the location of the minimum value (-4) that is greater than -5.
MINLOC (A, DIM=1) has the value (3, 3, 1, 3). 3 is the subscript of the location of the minimum value (-1) in column 1; 3 is the subscript of the location of the minimum value (-4) in column 2; and so forth.

MINLOC (A, DIM=2) has the value (3, 3, 4). 3 is the subscript of the location of the minimum value (-3) in row 1; 3 is the subscript of the location of the minimum value (-2) in row 2; and so forth.
The following shows another example:

```fortran
INTEGER i, minl(1)
INTEGER array(2, 3)
INTEGER, ALLOCATABLE :: AR1(:)
! put values in array
array = RESHAPE((/-7, 1, -2, -9, 5, 0/),(/2, 3/))
! array is -7 -2 5
! 1 -9 0
i = SIZE(SHAPE(array)) ! Get the number of dimensions
! in array
ALLOCATE (AR1 (i) ) ! Allocate AR1 to number
! of dimensions in array
AR1 = MINLOC (array, MASK = array .GT. -5) ! Get the
! location (subscripts) of
! smallest element greater
! than -5 in array
!
! MASK = array .GT. -5 creates a mask array the same
! size and shape as array whose elements are .TRUE. if
! the corresponding element in array is greater than
! -5, and .FALSE. if it is not. This mask causes MINLOC
! to return the index of the element in array with the
! smallest value greater than -5.
!
! array is -7 -2 5 and MASK= array .GT. -5 is T T T
! 1 -9 0          T F T
! and AR1 = MINLOC(array, MASK = array .GT. -5) returns
! (1, 2), the location of the element with value -2
minl = MINLOC((/-7, 2, -7, 5/)) ! returns 1, first
```
MINVAL

Transformational Intrinsic Function (Generic):
Returns the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax

\[ \text{result} = \text{MINVAL} \left( \text{array[,dim][,mask]} \right) \]

- **array** (Input) Must be an array of type integer or real.
- **dim** (Input; optional) Must be a scalar integer with a value in the range 1 to \( n \), where \( n \) is the rank of \( \text{array} \).
- **mask** (Input; optional) Must be a logical array that is conformable with \( \text{array} \).

Results

The result is an array or a scalar of the same data type as \( \text{array} \).

The result is a scalar if \( \text{dim} \) is omitted or \( \text{array} \) has rank one.

The following rules apply if \( \text{dim} \) is omitted:

- If \( \text{MINVAL}(\text{array}) \) is specified, the result has a value equal to the minimum value of all the elements in \( \text{array} \).
- If \( \text{MINVAL}(\text{array}, \text{MASK}=\text{mask}) \) is specified, the result has a value equal to the minimum value of the elements in \( \text{array} \) corresponding to the condition specified by \( \text{mask} \).

The following rules apply if \( \text{dim} \) is specified:
An array result has a rank that is one less than \( \text{array} \), and shape (\( d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n \)), where (\( d_1, d_2, \ldots, d_n \)) is the shape of \( \text{array} \).

- If \( \text{array} \) has rank one, \( \text{MINVAL}(\text{array}, \text{dim}[\text{, mask}]) \) has a value equal to that of \( \text{MINVAL}(\text{array}[\text{, MASK = mask}]) \). Otherwise, the value of element (\( s_1, s_2, \ldots, s_{\text{dim}-1}, s_{\text{dim}+1}, \ldots, s_n \)) of \( \text{MINVAL}(\text{array}, \text{dim}[\text{, mask}]) \) is equal to \( \text{MINVAL}(\text{array}(s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n)[\text{, MASK = mask}(s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n)]) \).

If \( \text{array} \) has size zero or if there are no true elements in \( \text{mask} \), the result (if \( \text{dim} \) is omitted), or each element in the result array (if \( \text{dim} \) is specified), has the value of the positive number of the largest magnitude supported by the processor for numbers of the type and kind parameters of \( \text{array} \).

**Example**

The value of \( \text{MINVAL}((/2, 3, 4/)) \) is 2 because that is the minimum value in the rank-one array.

The value of \( \text{MINVAL}(\text{B}, \text{MASK=\text{B .GT. 0.0}}) \) finds the minimum value of the positive elements of \( \text{B} \).

\( \text{C} \) is the array

\[
\begin{bmatrix}
  2 & 3 & 4 \\
  5 & 6 & 7 \\
\end{bmatrix}
\]

\( \text{MINVAL}(\text{C}, \text{DIM=1}) \) has the value (2, 3, 4). 2 is the minimum value in column 1; 3 is the minimum value in column 2; and so forth.

\( \text{MINVAL}(\text{C}, \text{DIM=2}) \) has the value (2, 5). 2 is the minimum value in row 1 and 5 is the minimum value in row 2.
The following shows another example:

```fortran
INTEGER array(2, 3), i(2), minv
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/), (/2, 3/))
! array is 1 5 3
! 4 2 6
i = SHAPE(array)  ! i = [2 3]
ALLOCATE(AR1(i(2)))  ! dimension AR1 to number of
! elements in dimension 2
! (a column) of array.
ALLOCATE(AR2(i(1)))  ! dimension AR2 to number of
! elements in dimension 1
! (a row) of array.
minv = MINVAL(array, MASK = array .GT. 4)  ! returns 5
AR1 = MINVAL(array, DIM = 1)  ! returns [1 2 3]
AR2 = MINVAL(array, DIM = 2)  ! returns [1 2]
END
```

**MM_PREFETCH**

_Intrinsic Subroutine (Generic):_ Prefetches data from the specified address on one memory cache line. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL MM_PREFETCH (address[,hint] [,fault] [,exclusive])
```
address (Input) is the name of a scalar or array; it can be of any type or rank. It specifies the address of the data on the cache line to prefetch.

hint (Input; optional) is an optional default integer constant with one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Prefetch Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FOR_K_PREFETCH_T0</td>
<td>Prefetches into the L1 cache (and the L2 and the L3 cache). Use this for integer data.</td>
</tr>
<tr>
<td>1</td>
<td>FOR_K_PREFETCH_T1</td>
<td>Prefetches into the L2 cache (and the L3 cache); floating-point data is used from the L2 cache, not the L1 cache. Use this for real data.</td>
</tr>
<tr>
<td>2</td>
<td>FOR_K_PREFETCH_T2</td>
<td>Prefetches into the L2 cache (and the L3 cache); this line will be marked for early displacement. Use this if you are not going to reuse the cache line frequently.</td>
</tr>
<tr>
<td>3</td>
<td>FOR_K_PREFETCH_NTA</td>
<td>Prefetches into the L2 cache (but not the L3 cache); this line will be marked for early displacement. Use</td>
</tr>
</tbody>
</table>
Value | Prefetch Constant | Description
--- | --- | ---
 |  | this if you are not going to reuse the cache line.

The preceding constants are defined in file `fordef.for` on Windows* systems and file `fordef.f` on Linux* and Mac OS* X systems.

If `hint` is omitted, 0 is assumed.

**fault**

(Input; optional) Is an optional default logical constant. If .TRUE. is specified, page faults are allowed to occur, if necessary; if .FALSE. is specified, page faults are not allowed to occur. If `fault` is omitted, .FALSE. is assumed. This argument is ignored on Intel® 64 architecture and IA-32 architecture.

**exclusive**

(Input; optional) Is an optional default logical constant. If .TRUE. is specified, you get exclusive ownership of the cache line because you intend to assign to it; if .FALSE. is specified, there is no exclusive ownership. If `exclusive` is omitted, .FALSE. is assumed. This argument is ignored on Intel® 64 architecture and IA-32 architecture.
Example

subroutine spread_lf (a, b)
PARAMETER (n = 1025)
real*8 a(n,n), b(n,n), c(n)
do j = 1,n
do i = 1,100
   a(i, j) = b(i-1, j) + b(i+1, j)
call mm_prefetch (a(i+20, j), 1)
call mm_prefetch (b(i+21, j), 1)
enddo
endo
doo
print *, a(2, 567)
stop
end

MOD

Elemental Intrinsic Function (Generic):
Returns the remainder when the first argument is divided by the second argument.

Syntax

result = MOD (a, p)

a       (Input) Must be of type integer or real.
P       (Input) Must have the same type and kind parameters as a.

Results

The result type is the same as a. If p is not equal to zero, the value of the result is a - INT( a/p ) * p. If p is equal to zero, the result is undefined.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BMOD</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>Specific Name</td>
<td>Argument Type</td>
<td>Result Type</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>IMOD(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>MOD(^2)</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KMOD</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
<tr>
<td>AMOD(^3)</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DMOD(^3,4)</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QMOD</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\) Or HMOD.

\(^2\) Or JMOD.

\(^3\) The setting of compiler options specifying real size can affect AMOD and DMOD.

\(^4\) The setting of compiler options specifying double size can affect DMOD.

**Example**

MOD (7, 3) has the value 1.

MOD (9, -6) has the value 3.

MOD (-9, 6) has the value -3.

The following shows more examples:

```
INTEGER I
REAL R
R = MOD(9.0, 2.0)  ! returns 1.0
I = MOD(18, 5)     ! returns 3
I = MOD(-18, 5)    ! returns -3
```

**See Also**

- M to N
- MODULO
MODIFYMENUFLAGSQQ (W*32, W*64)

QuickWin Function: Modifies a menu item's state.

Module

USE IFQWIN

Syntax

result = MODIFYMENUFLAGSQQ (menuID, itemID, flag)

menuID (Input) INTEGER(4). Identifies the menu containing the item whose state is to be modified, starting with 1 as the leftmost menu.

itemID (Input) INTEGER(4). Identifies the menu item whose state is to be modified, starting with 0 as the top item.

flags (Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see below). The following constants are available:

- #$MENUGRAYED - Disables and grays out the menu item.
- #$MENUDISABLED - Disables but does not gray out the menu item.
- #$MENUENABLED - Enables the menu item.
- #$MENUSEPARATOR - Draws a separator bar.
- #$MENUCHECKED - Puts a check by the menu item.
- #$MENUUNCHECKED - Removes the check by the menu item.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The constants available for flags can be combined with an inclusive OR where reasonable, for example #$MENUCHECKED .OR. #$MENUENABLED. Some combinations do not make sense, such as #$MENUENABLED and #$MENUDISABLED, and lead to undefined behavior.

Compatibility

QUICKWIN GRAPHICS LIB
Example

USE IFQWIN
LOGICAL(4) result
CHARACTER(20) str

! Append item to the bottom of the first (FILE) menu
str = 'Add to File Menu'
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)

! Gray out and disable the first two menu items in the
! first (FILE) menu
result = MODIFYMENUFLAGSQQ (1, 1, $MENUGRAYED)
result = MODIFYMENUFLAGSQQ (1, 2, $MENUGRAYED)
END

Building Applications: Using QuickWin Overview
Building Applications: Program Control of Menus

MODIFYMENUROUTINEQQ (W*32, W*64)

QuickWin Function: Changes a menu item's callback routine.

Module
USE IFQWIN

Syntax

result = MODIFYMENUROUTINEQQ (menuIdD, itemID, routine)
**menuID**
(Input) INTEGER(4). Identifies the menu that contains the item whose callback routine is to be changed, starting with 1 as the leftmost menu.

**itemId**
(Input) INTEGER(4). Identifies the menu item whose callback routine is to be changed, starting with 0 as the top item.

**routine**
(Input) EXTERNAL. Callback subroutine called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:

- **WINPRINT** - Prints the program.
- **WINSAVE** - Saves the program.
- **WINEXIT** - Terminates the program.
- **WINSELECTTEXT** - Selects text from the current window.
- **WINSELECTGRAPHICS** - Selects graphics from the current window.
- **WINSELECTALL** - Selects the entire contents of the current window.
- **WININPUT** - Brings to the top the child window requesting input and makes it the current window.
- **WINCOPY** - Copies the selected text and/or graphics from the current window to the Clipboard.
- **WINPASTE** - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
- **WINCLEARPASTE** - Clears the paste buffer.
- **WINSIZETOFIT** - Sizes output to fit window.
- **WINFULLSCREEN** - Displays output in full screen.
- **WINSTATE** - Toggles between pause and resume states of text output.
- **WINCASCADE** - Cascades active windows.
- **WINTILE** - Tiles active windows.
- **WINARRANGE** - Arranges icons.
- **WINSTATUS** - Enables a status bar.
• WININDEX - Displays the index for QuickWin help.
• WINUSING - Displays information on how to use Help.
• WINABOUT - Displays information about the current QuickWin application.
• NUL - No callback routine.

**Results**
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

**Compatibility**
QUICKWIN GRAPHICS LIB

*Building Applications: Using QuickWin Overview*
*Building Applications: Program Control of Menus*

**MODIFYMENUSTRINGQQ (W*32, W*64)**

*QuickWin Function: Changes a menu item's text string.*

**Module**
USE IIFQWIN

**Syntax**

```plaintext
result = MODIFYMENUSTRINGQQ (menuID, itemID, text)
```

*menuID* (Input) INTEGER(4). Identifies the menu containing the item whose text string is to be changed, starting with 1 as the leftmost item.
**itemID**
(Input) INTEGER(4). Identifies the menu item whose text string is to be changed, starting with 0 as the top menu item.

**text**
(Input) Character(*(*). Menu item name. Must be a null-terminated C string. For example, words of text 'C.

**Results**
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can add access keys in your text strings by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, use "P&rint"C as text.

**Compatibility**
QUICKWIN GRAPHICS LIB

**Example**

USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str

! Append item to the bottom of the first (FILE) menu
str = '&Add to File Menu'C
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)

! Change the name of the first item in the first menu
str = '&Browse'C
result = MODIFYMENUSTRINGQQ (1, 1, str)
END

*Building Applications*: Displaying Character-Based Text

**MODULE**

**Statement**: Marks the beginning of a module program unit, which contains specifications and definitions that can be used by one or more program units.

**Syntax**

```
MODULE  name
   [specification-part]
[CONTAINS
   module-subprogram
   [module-subprogram]...]
END[ MODULE  name]
```

- **name**
  Is the name of the module.

- **specification-part**
  Is one or more specification statements, except for the following:
  - ENTRY
  - FORMAT
  - AUTOMATIC (or its equivalent attribute)
  - INTENT (or its equivalent attribute)
  - OPTIONAL (or its equivalent attribute)
  - Statement functions

- **module-subprogram**
  Is a function or subroutine subprogram that defines the *module procedure*. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE. A module subprogram can contain internal procedures.
Description

If a name follows the END statement, it must be the same as the name specified in the MODULE statement.

The module name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A module is host to any module procedures it contains, and entities in the module are accessible to the module procedures through host association.

A module must not reference itself (either directly or indirectly).

You can use the PRIVATE attribute to restrict access to procedures or variables within a module. Although ENTRY statements, FORMAT statements, and statement functions are not allowed in the specification part of a module, they are allowed in the specification part of a module subprogram.

Any executable statements in a module can only be specified in a module subprogram.

A module can contain one or more procedure interface blocks, which let you specify an explicit interface for an external subprogram or dummy subprogram.

Example

The following example shows a simple module that can be used to provide global data:

```fortran
MODULE MOD_A
  INTEGER :: B, C
  REAL E(25,5)
END MODULE MOD_A
...
SUBROUTINE SUB_Z
  USE MOD_A ! Makes scalar variables B and C, and array
  ...
  ! E available to this subroutine
END SUBROUTINE SUB_Z
```
The following example shows a module procedure:

```fortran
MODULE RESULTS
...
CONTAINS
    FUNCTION MOD_RESULTS(X,Y) ! A module procedure
    ...
    END FUNCTION MOD_RESULTS
END MODULE RESULTS
```

The following example shows a module containing a derived type:

```fortran
MODULE EMPLOYEE_DATA
    TYPE EMPLOYEE
        INTEGER ID
        CHARACTER(LEN=40) NAME
    END TYPE EMPLOYEE
END MODULE
```

The following example shows a module containing an interface block:

```fortran
MODULE ARRAY_CALCULATOR
    INTERFACE
        FUNCTION CALC_AVERAGE(D)
            REAL :: CALC_AVERAGE
            REAL, INTENT(IN) :: D(:)
        END FUNCTION
    END INTERFACE
END MODULE
```
The following example shows a derived-type definition that is public with components that are private:

```fortran
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
    INTEGER C, D
  END TYPE
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

This design allows you to change components of a type without affecting other program units that use the module.
If a derived type is needed in more than one program unit, the definition should be placed in a module and accessed by a USE statement whenever it is needed, as follows:

```fortran
MODULE STUDENTS
  TYPE STUDENT_RECORD
    ...
  END TYPE
CONTAINS
  SUBROUTINE COURSE_GRADE(...)
    TYPE(STUDENT_RECORD) NAME ...
  END SUBROUTINE
END MODULE STUDENTS
END MODULE STUDENTS
...
PROGRAM SENIOR_CLASS
  USE STUDENTS
  TYPE(STUDENT_RECORD) ID ...
END PROGRAM
```

Program SENIOR_CLASS has access to type STUDENT_RECORD, because it uses module STUDENTS. Module procedure COURSE_GRADE also has access to type STUDENT_RECORD, because the derived-type definition appears in its host.
The following shows another example:

```fortran
MODULE mod1
   REAL(8) a,b,c,d
   INTEGER(4) Int1, Int2, Int3
CONTAINS
   function fun1(x)
   ....
   end function fun1
END MODULE
```

**See Also**
- M to N
- PUBLIC
- PRIVATE
- USE
- Procedure Interfaces
- Program Units and Procedures
- PROTECTED Attribute and Statement
MODULE PROCEDURE

Statement: Identifies module procedures in an interface block that specifies a generic name. See INTERFACE.

Example

!A program that changes non-default integers and reals !into default integers and reals

PROGRAM CHANGE_KIND
USE Module1
INTERFACE DEFAULT
MODULE PROCEDURE Sub1, Sub2
END INTERFACE
integer(2) in
integer indef
indef = DEFAULT(in)
END PROGRAM

! procedures sub1 and sub2 defined as follows:

MODULE Module1
CONTAINS
FUNCTION Sub1(y)
REAL(8) y
sub1 = REAL(y)
END FUNCTION
FUNCTION Sub2(z)
INTEGER(2) z
sub2 = INT(z)
END FUNCTION
END MODULE
MODULO

*Elemental Intrinsic Function (Generic):*

*Returns the modulo of the arguments.*

**Syntax**

\[
\text{result} = \text{MODULO} \left( a, p \right)
\]

- \( a \) (Input) Must be of type integer or real.
- \( p \) (Input) Must have the same type and kind parameters as \( a \).

**Results**

The result type is the same \( a \). The result value depends on the type of \( a \), as follows:

- If \( a \) is of type integer and \( P \) is not equal to zero, the value of the result is \( a - \text{FLOOR}(\text{REAL}(a)/\text{REAL}(p)) \times p \).
- If \( a \) is of type real and \( p \) is not equal to zero, the value of the result is \( a - \text{FLOOR}(a/p) \times p \).

If \( p \) is equal to zero (regardless of the type of \( a \)), the result is undefined.

**Example**

MODULO \((7, 3)\) has the value 1.
MODULO \((9, -6)\) has the value -3.
MODULO \((-9, 6)\) has the value 3.
The following shows more examples:

```plaintext
INTEGER I
REAL R

I = MODULO(8, 5)       ! returns 3     Note: q=1
I = MODULO(-8, 5)      ! returns 2     Note: q=-2
I = MODULO(8, -5)      ! returns -2    Note: q=-2
R = MODULO(7.285, 2.35) ! returns 0.2350001 Note: q=3
R = MODULO(7.285, -2.35) ! returns -2.115 Note: q=-4
```

See Also

- M to N
- MOD

MOVE_ALLOC

**Intrinsic Subroutine (Generic):** Moves an allocation from one allocatable object to another. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```plaintext
CALL MOVE_ALLOC (from, to)
```

- `from` (Input; output) Can be of any type and rank; it must be allocatable.
- `to` (Output) Must have the same type and kind parameters as `from` and have the same rank; it must be allocatable.

If `to` is currently allocated, it is deallocated. If `from` is allocated, `to` becomes allocated with the same type, type parameters, array bounds, and value as `from`. Lastly, `from` is deallocated.

If `to` has the TARGET attribute, any pointer associated with `from` at the time of the call to MOVE_ALLOC becomes correspondingly associated with `to`. If `to` does not have the TARGET attribute, the pointer association status of any pointer associated with `from` on entry becomes undefined.

During implementation of MOVE_ALLOC, the internal descriptor contents are copied from `from` to `to`, so that the storage pointed to is the same.

Typically, MOVE_ALLOC is used to provide an efficient way to reallocate a variable to a larger size without copying the data twice.
Example

The following shows an example of how to increase the allocated size of A and keep the old values with only one copy of the old values.

```fortran
integer, allocatable :: a(:,), b(:)
n = 2
allocate (a(n), b(n*2))
a = (/ (i, i=1, n) /)
b = -1
print *, ' Old a = ', a
print *, ' Old b = ', b
print *, ' Allocated(a), allocated(b) = ', allocated(a), allocated(b)
b(1:n) = a ! Copy all of a into low end of b (the only copy)
print *, ' New b = ', b
call move_alloc(b, a) ! Make a the container, deallocate b (NO copy!)
print *, ' New a = ', a
print *, ' Allocated(a), allocated(b) = ', allocated(a), allocated(b)
end
```
The following shows another example:

! This program uses MOVE_ALLOC to make an allocated array X bigger and
! keep the old values of X by only making one copy of the old values of X

integer :: n = 2
real, allocatable :: x(:), y(:)
allocate (x(n), y(2*n)) ! Y is bigger than X
x = (/i,i=1,n/) ! put "old values" into X
y = -1 ! put different "old values" into Y
print *, ' allocated of X is ', allocated(X)
print *, ' allocated of Y is ', allocated(Y)
print *, ' old X is ', X
print *, ' old Y is ', Y
y (1:n) = x ! copy all of X into the first locations of Y
! this is the only copying of values required
print *, ' new Y is ', y
call move_alloc (y, x) ! X is now twice a big as it was, Y is
! deallocated, the values were not copied
print *, ' allocated of X is ', allocated(X)
print *, ' allocated of Y is ', allocated(Y)
print *, ' new X is ', x
end
The following shows the output for the above example:

*allocated of X is T*
*allocated of Y is T*

*old X is 1.000000 2.000000*
*old Y is -1.000000 -1.000000 -1.000000 -1.000000*
*new Y is 1.000000 2.000000 -1.000000 -1.000000*
*allocated of X is T*
*allocated of Y is F*
*new X is 1.000000 2.000000 -1.000000 -1.000000*

**MOVETO, MOVETO_W** (*W*32, *W*64)

**Graphics Subroutines:** Move the current graphics position to a specified point. No drawing occurs.

**Module**

USE IFQWIN

**Syntax**

CALL MOVETO (x, y, t)

CALL MOVETO_W (wx, wy, wt)

**x, y** (Input) INTEGER(2). Viewport coordinates of the new graphics position.

**t** (Output) Derived type xycoord. Viewport coordinates of the previous graphics position. The derived type xycoord is defined in IFQWIN.F90 as follows:

```
TYPE xycoord
  INTEGER(2) xcoord ! x coordinate
  INTEGER(2) ycoord ! y coordinate
END TYPE xycoord
```

**wx, wy** (Input) REAL(8). Window coordinates of the new graphics position.
(Output) Derived type wxycoord. Window coordinates of the previous graphics position. The derived type wxycoord is defined in IFQWIN.F90

```fortran
TYPE wxycoord
    REAL(8) wx  ! x window coordinate
    REAL(8) wy  ! y window coordinate
END TYPE wxycoord
```

MOVETO sets the current graphics position to the viewport coordinate (x, y). MOVETO_W sets the current graphics position to the window coordinate (wx, wy).

MOVETO and MOVETO_W assign the coordinates of the previous position to t and wt, respectively.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

```fortran
! Build as QuickWin or Standard Graphics ap.
USE IFQWIN
INTEGER(2) status, x, y
INTEGER(4) result
TYPE (xycoord) xy
RESULT = SETCOLORRGB(Z'FF0000') ! blue
x = 60
! Draw a series of lines
DO y = 50, 92, 3
    CALL MOVETO(x, y, xy)
    status = LINETO(INT2(x + 20), y)
END DO
END
```

*Building Applications: Drawing Lines on the Screen*

*Building Applications: SHOWFONT.F90 Example*

*Building Applications: Using Fonts from the Graphics Library Overview*

**MULT_HIGH (i64 only)**

*Elemental Intrinsic Function (Specific):*

Multiplies two 64-bit unsigned integers. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{MULT\_HIGH} (i, j)
\]

\[
i \quad \text{(Input) Must be of type INTEGER(8).}
\]

\[
j \quad \text{(Input) Must be of type INTEGER(8).}
\]

**Results**

The result type is INTEGER(8). The result value is the upper (leftmost) 64 bits of the 128-bit unsigned result.
Example

Consider the following:

```fortran
INTEGER(8) I,J,K
I=2_8**53
J=2_8**51
K = MULT_HIGH (I,J)
PRINT *,I,J,K
WRITE (6,1000)I,J,K
1000 FORMAT (' ', 3(Z,1X))
END
```

This example prints the following:

```
9007199254740992 2251799813685248 1099511627776
20000000000000 8000000000000 10000000000
```

**MULT_HIGH_SIGNED (i64 only)**

*Elemental Intrinsic Function (Specific):* Multiplies two 64-bit signed integers. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

**Syntax**

```
result = MULT_HIGH_SIGNED (i,j)
```

i  (Input) Must be of type INTEGER(8).

j  (Input) Must be of type INTEGER(8).

**Results**

The result type is INTEGER(8). The result value is the upper (leftmost) 64 bits of the 128-bit signed result.
Example

Consider the following:

```fortran
INTEGER(8) I,J,K
I=2_8**53
J=2_8**51
K = MULT_HIGH_SIGNED (I,J)
PRINT *,I,J,K
WRITE (6,1000)I,J,K
1000 FORMAT (' ', 3(Z,1X))
END
```

This example prints the following:

```
9007199254740992 -2251799813685248 -1099511627776
20000000000000 FFF8000000000000 FFFFFF0000000000
```

MVBITS

**Elemental Intrinsic Subroutine (Generic):**
Copies a sequence of bits (a bit field) from one location to another. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL MVBITS (from,frompos,len,to,topos)
```

- **from** (Input) Integer. Can be of any integer type. It represents the location from which a bit field is transferred.
- **frompos** (Input) Can be of any integer type; it must not be negative. It identifies the first bit position in the field transferred from `from`. `frompos + len` must be less than or equal to `BIT_SIZE(from)`.
- **len** (Input) Can be of any integer type; it must not be negative. It identifies the length of the field transferred from `from`. 
to

(Input; output) Can be of any integer type, but must have the same kind parameter as from. It represents the location to which a bit field is transferred. to is set by copying the sequence of bits of length len, starting at position frompos of from to position topos of to. No other bits of to are altered.

topos

(Input) Can be of any integer type; it must not be negative. It identifies the starting position (within to) for the bits being transferred. topos + len must be less than or equal to BIT_SIZE(to).

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

You can also use the following specific routines:

BMVBITS

Arguments from and to must be INTEGER(1).

HMVBITS

Arguments from and to must be INTEGER(2).

IMVBITS

Arguments from and to must be INTEGER(2).

JMVBITS

Arguments from and to must be INTEGER(4).

KMVBITS

Arguments from and to must be INTEGER(8).

Example

If TO has the initial value of 6, its value after a call to MVBITS(7, 2, 2, TO, 0) is 5.

The following shows another example:

INTEGER(1) :: from = 13  ! 00001101
INTEGER(1) :: to = 6    ! 00000110
CALL MVBITS(from, 2, 2, to, 0) ! returns to = 00000111
END

- M to N
- BIT_SIZE
NAMELIST

Statement: Associates a name with a list of variables. This group name can be referenced in some input/output operations.

Syntax

NAMELIST /group/ var-list[[,] /group/ var-list]...

- group is the name of the group.
- var-list is a list of variables (separated by commas) that are to be associated with the preceding group name. The variables can be of any data type.

Description

The namelist group name is used by namelist I/O statements instead of an I/O list. The unique group name identifies a list whose entities can be modified or transferred.

A variable can appear in more than one namelist group.

Each variable in var-list must be accessed by use or host association, or it must have its type, type parameters, and shape explicitly or implicitly specified in the same scoping unit. If the variable is implicitly typed, it can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

The following variables cannot be specified in a namelist group:

- An array dummy argument with nonconstant bounds
- A variable with assumed character length
- An allocatable array
- A pointer
- A variable of a type that has a pointer as an ultimate component
- A subobject of any of the above objects

• IBCLR
• IBSET
• ISHFT
• ISHFTC
Only the variables specified in the namelist can be read or written in namelist I/O. It is not necessary for the input records in a namelist input statement to define every variable in the associated namelist.

The order of variables in the namelist controls the order in which the values appear on namelist output. Input of namelist values can be in any order.

If the group name has the PUBLIC attribute, no item in the variable list can have the PRIVATE attribute.

The group name can be specified in more than one NAMELIST statement in a scoping unit. The variable list following each successive appearance of the group name is treated as a continuation of the list for that group name.

Example

In the following example, D and E are added to the variables A, B, and C for group name LIST:

```
NAMELIST /LIST/ A, B, C
NAMELIST /LIST/ D, E
```

In the following example, two group names are defined:

```
CHARACTER*30 NAME(25)
NAMELIST /INPUT/ NAME, GRADE, DATE /OUTPUT/ TOTAL, NAME
```

Group name INPUT contains variables NAME, GRADE, and DATE. Group name OUTPUT contains variables TOTAL and NAME.
The following shows another example:
NAMELIST /example/ i1, l1, r4, r8, z8, z16, c1, c10, iarray
! The corresponding input statements could be:
&example
i1 = 11
l1 = .TRUE.
r4 = 24.0
r8 = 28.0d0
z8 = (38.0, 0.0)
z16 = (316.0d0, 0.0d0)
c1 = 'A'
c10 = 'abcdefghij'
iarray(8) = 41, 42, 43
/

A sample program, NAMELIST.F90, is included in the <install-dir>/samples subdirectory.

NARGS
_Inquiry Intrinsic Function (Specific):_ Returns the total number of command-line arguments, including the command. This function cannot be passed as an actual argument.

Syntax

```fortran
result = NARGS()
```

3066
Results

The result type is INTEGER(4). The result is the number of command-line arguments, including the command. For example, NARGS returns 4 for the command-line invocation of `PROG1 -g -c -a`. 
Example

INTEGER(2) result
result = RUNQQ('myprog', '-c -r')
END

! MYPROG.F90 responds to command switches -r, -c, ! and/or -d
INTEGER(4) count, num, i, status
CHARACTER(80) buf
REAL r1 / 0.0 /
COMPLEX c1 / (0.0,0.0) /
REAL(8) d1 / 0.0 /
num = 5
count = NARGS()
DO i = 1, count-1
   CALL GETARG(i, buf, status)
   IF (status .lt. 0) THEN
      WRITE (*,*) 'GETARG error - exiting'
      EXIT
   END IF
   IF (buf(2:status) .EQ.'r') THEN
      r1 = REAL(num)
      WRITE (*,*) 'r1 = ',r1
   ELSE IF (buf(2:status) .EQ.'c') THEN
      c1 = CMPLX(num)
      WRITE (*,*) 'c1 = ', c1
   ELSE IF (buf(2:status) .EQ.'d') THEN
      d1 = DBLE(num)
      WRITE (*,*) 'd1 = ', d1
   END IF
ELSE
    WRITE(*,*) 'Invalid command switch: ', buf (1:status)
END IF
END DO
END

NEAREST

*Elemental Intrinsic Function (Generic)*: Returns the nearest different number (representable on the processor) in a given direction.

Syntax

\[
\text{result} = \text{NEAREST} (x, s)
\]

\(x\)  
(Input) Must be of type real.

\(s\)  
(Input) Must be of type real and nonzero.

Results

The result type is the same as \(x\). The result has a value equal to the machine representable number that is different from and nearest to \(x\), in the direction of the infinity with the same sign as \(s\).

Example

If 3.0 and 2.0 are REAL(4) values, NEAREST (3.0, 2.0) has the value \(3 + 2^{-22}\), which equals approximately 3.0000002. (For more information on the model for REAL(4), see Model for Real Data.)
The following shows another example:

```fortran
REAL(4) r1
REAL(8) r2, result
r1 = 3.0
result = NEAREST (r1, -2.0)
WRITE(*,*) result ! writes 2.999999761581421
! When finding nearest to REAL(8), can't see
! the difference unless output in HEX
r2 = 111502.07D0
result = NEAREST(r2, 2.0)
WRITE(*,'(1x,Z16)') result ! writes 40FB38E11EB851ED
result = NEAREST(r2, -2.0)
WRITE(*,'(1x,Z16)') result ! writes 40FB38E11EB851EB
END
```

- EPSILON

**NEW_LINE**

*Inquiry Intrinsic Function (Generic):* Returns a new line character.

**Syntax**

```fortran
result = NEW_LINE(a)
```

`a` (Input) Must be of type default character. It may be a scalar or an array.

**Results**

The result is a character scalar of length one with the same kind type parameter as `a`. The result value is the ASCII newline character ACHAR(10).
**NINT**

*Elemental Intrinsic Function (Generic):*

Returns the nearest integer to the argument.

**Syntax**

\[
\text{result} = \text{NINT}(a[,\text{kind}])
\]

- \(a\) (Input) Must be of type real.
- \(\text{kind}\) (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is integer. If \(\text{kind}\) is present, the kind parameter of the result is that specified by \(\text{kind}\); otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If \(a\) is greater than zero, \(\text{NINT}(a)\) has the value \(\text{INT}(a + 0.5)\); if \(a\) is less than or equal to zero, \(\text{NINT}(a)\) has the value \(\text{INT}(a - 0.5)\).

</table>

<sup>1</sup> Or JNINT.
The setting of compiler options specifying integer size can affect NINT, IDNINT, and IQNINT.

Or JIDNNT. For compatibility with older versions of Fortran, IDNINT can also be specified as a generic function.

Or JIQNNT. For compatibility with older versions of Fortran, IQNINT can also be specified as a generic function.

Example

NINT (3.879) has the value 4.
NINT (-2.789) has the value -3.

The following shows another example:

```
INTEGER(4) i1, i2
i1 = NINT(2.783) ! returns 3
i2 = IDNINT(-2.783D0) ! returns -3
```

**NLSEnumCodepages (W*32, W*64)**

**NLS Function:** Returns an array containing the codepages supported by the system, with each array element describing one valid codepage.

**Module**

```
USE IFNLS
```

**Syntax**

```
ptr=> NLSEnumCodepages( )
```

**Results**

The result is a pointer to an array of codepages, with each element describing one supported codepage.
NOTE. After use, the pointer returned by NLSEnumCodepages should be deallocated with the DEALLOCATE statement.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Building Applications: Locale Setting and Inquiry Routines

NLSEnumLocales (W*32, W*64)

NLS Function: Returns an array containing the language and country combinations supported by the system, in which each array element describes one valid combination.

Module
USE IFNLS

Syntax
ptr=> NLSEnumLocales( )

Results
The result is a pointer to an array of locales, in which each array element describes one supported language and country combination. Each element has the following structure:

```
TYPE NLS$EnumLocale
  CHARACTER*(NLS$MaxLanguageLen) Language
  CHARACTER*(NLS$MaxCountryLen) Country
  INTEGER(4) DefaultWindowsCodepage
  INTEGER(4) DefaultConsoleCodepage
END TYPE
```
If the application is a Windows or QuickWin application, NLS$DefaultWindowsCodepage is the codepage used by default for the given language and country combination. If the application is a console application, NLS$DefaultConsoleCodepage is the codepage used by default for the given language and country combination.

NOTE. After use, the pointer returned by NLSEnumLocales should be deallocated with the DEALLOCATE statement.

NLSFormatCurrency (W*32, W*64)

NLS Function: Returns a correctly formatted currency string for the current locale.

Module
USE IFNLS

Syntax
result = NLSFormatCurrency (outstr, instr[, flags])

outstr (Output) Character*(*). String containing the correctly formatted currency for the current locale. If outstr is longer than the formatted currency, it is blank-padded.

instr (Input) Character*(*). Number string to be formatted. Can contain only the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.
flags (Input; optional) INTEGER(4). If specified, modifies the currency conversion. If you omit flags, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:

- NLS$Normal - No special formatting
- NLS$NoUserOverride - Do not use user overrides

Results
The result type is INTEGER(4). The result is the number of characters written to outstr (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLS$ErrorInsufficientBuffer - outstr buffer is too small
- NLS$ErrorInvalidFlags - flags has an illegal value
- NLS$ErrorInvalidInput - instr has an illegal value

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFNLS
CHARACTER(40) str
INTEGER(4) i
i = NLSFormatCurrency(str, "1.23")
print *, str ! prints $1.23
i = NLSFormatCurrency(str, "1000000.99")
print *, str ! prints $1,000,000.99
i = NLSSetLocale("Spanish", "Spain")
i = NLSFormatCurrency(str, "1.23")
print *, str ! prints 1 Pts
i = NLSFormatCurrency(str, "1000000.99")
print *, str ! prints 1.000.001 Pts

- NLSFormatDate
- NLSFormatTime

Building Applications: NLS Formatting Routines

NLSFormatDate (W*32, W*64)

NLS Function: Returns a correctly formatted string containing the date for the current locale.

Module

USE IFNLS

Syntax

result = NLSFormatDate (outstr[,intime] [,flags])

outstr
(Output) Character*(*) String containing the correctly formatted date for the current locale. If outstr is longer than the formatted date, it is blank-padded.

intime
(Input; optional) INTEGER(4) If specified, date to be formatted for the current locale. Must be an integer date such as the packed time created with PACKTIMEQQ. If you omit intime, the current system date is formatted and returned in outstr.

flags
(Input; optional) INTEGER(4) If specified, modifies the date conversion. If you omit flags, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:

- NLS$Normal - No special formatting
- NLS$NoUserOverride - Do not use user overrides
- NLS$UseAltCalendar - Use the locale's alternate calendar
- NLS$LongDate - Use local long date format
- NLS$ShortDate - Use local short date format
Results
The result type is INTEGER(4). The result is the number of characters written to outstr (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLS$ErrorInsufficientBuffer - outstr buffer is too small
- NLS$ErrorInvalidFlags - flags has an illegal value
- NLS$ErrorInvalidInput - intime has an illegal value

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFNLS
INTEGER(4) i
CHARACTER(40) str
i = NLSFORMATDATE(str, NLS$NORMAL) ! 8/1/99
i = NLSFORMATDATE(str, NLS$USEALTCALENDAR) ! 8/1/99
i = NLSFORMATDATE(str, NLS$LONGDATE) ! Monday, August 1, 1999
i = NLSFORMATDATE(str, NLS$SHORTDATE) ! 8/1/99
END

Building Applications: NLS Formatting Routines
**NLSFormatNumber (W*32, W*64)**

**NLS Function:** Returns a correctly formatted number string for the current locale.

**Module**
USE IFNLS

**Syntax**

```fortran
result = NLSFormatNumber(outstr, instr[, flags])
```

- **outstr**
  (Output) Character*. String containing the correctly formatted number for the current locale. If `outstr` is longer than the formatted number, it is blank-padded.

- **instr**
  (Input) Character*. Number string to be formatted. Can only contain the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.

- **flags**
  (Input; optional) INTEGER(4). If specified, modifies the number conversion. If you omit `flags`, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:
    - NLS$Normal - No special formatting
    - NLS$NoUserOverride - Do not use user overrides

**Results**

The result type is INTEGER(4). The result is the number of characters written to `outstr` (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLS$ErrorInsufficientBuffer - `outstr` buffer is too small
- NLS$ErrorInvalidFlags - `flags` has an illegal value
- NLS$ErrorInvalidInput - `instr` has an illegal value
Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFNLS

CHARACTER(40) str
INTEGER(4) i

i = NLSFormatNumber(str, "1.23")
print *, str ! prints 1.23
i = NLSFormatNumber(str, "1000000.99")
print *, str ! prints 1,000,000.99
i = NLSSetLocale("Spanish", "Spain")
i = NLSFormatNumber(str, "1.23")

NLSFormatTime (W*32, W*64)

**NLS Function:** Returns a correctly formatted string containing the time for the current locale.

Module

USE IFNLS

Syntax

result = NLSFormatTime (outstr [, intime] [, flags])
outstr (Output) Character(*) String containing the correctly formatted time for the current locale. If outstr is longer than the formatted time, it is blank-padded.

intime (Input; optional) INTEGER(4). If specified, time to be formatted for the current locale. Must be an integer time such as the packed time created with PACKTIMEQQ. If you omit intime, the current system time is formatted and returned in outstr.

flags (Input; optional) INTEGER(4). If specified, modifies the time conversion. If you omit flags, the flag NLS$Normal is used. Available values (defined in IFNLS.F90) are:

- NLS$Normal - No special formatting
- NLS$NoUserOverride - Do not use user overrides
- NLS$NoMinutesOrSeconds - Do not return minutes or seconds
- NLS$NoSeconds - Do not return seconds
- NLS$NoTimeMarker - Do not add a time marker string
- NLS$Force24HourFormat - Return string in 24 hour format

Results
The result type is INTEGER(4). The result is the number of characters written to outstr (bytes are counted, not multibyte characters). If an error occurs, the result is one of the following negative values:

- NLS$ErrorInsufficientBuffer - outstr buffer is too small
- NLS$ErrorInvalidFlags - flags has an illegal value
- NLS$ErrorInvalidInput - intime has an illegal value

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFNLS

INTEGER(4) i
CHARACTER(20) str

i = NLSFORMATTIME(str, NLS$NORMAL) ! 11:38:28 PM
i = NLSFORMATTIME(str, NLS$NOMINUTESORSECONDS) ! 11 PM
i = NLSFORMATTIME(str, NLS$NOTIMEMARKER) ! 11:38:28 PM
i = NLSFORMATTIME(str, IOR(NLS$FORCE24HOURFORMAT, &
& NLS$NOSECONDS)) ! 23:38 PM

END

Building Applications: NLS Formatting Routines

NLSGetEnvironmentCodepage (W*32, W*64)

NLS Function: Returns the code page number for the system (Window) codepage or the console codepage.

Module

USE IFNLS

Syntax

result = NLSGetEnvironmentCodepage (flags)

flags (Input) INTEGER(4). Tells the function which code page number to return. Available values (defined in IFNLS.F90) are:

• NLS$ConsoleEnvironmentCodepage - Gets the code page for the console
NLS$WindowsEnvironmentCodepage - Gets the current Windows codepage

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, it returns one of the following error codes:
- NLS$ErrorInvalidFlags - flags has an illegal value
- NLS$ErrorNoConsole - There is no console associated with the given application; so, operations with the console codepage are not possible

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
- M to N
- NLSSetEnvironmentCodepage

Building Applications: Locale Setting and Inquiry Routines

NLSGetLocale (W*32, W*64)

*NLS Subroutine: Returns the current language, country, or codepage.*

Module
USE IFNLS

Syntax
CALL NLSGetLocale ([language] [,country] [,codepage])

language (Output; optional) Character*(*) Current language.
country (Output; optional) Character*(*) Current country.
codepage (Output; optional) INTEGER(4) Current codepage.

NLSGetLocale returns a valid codepage in codepage. It does not return one of the NLS$... symbolic constants that can be used with NLSSetLocale.
**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFNLS

CHARACTER(50) cntry, lang

INTEGER(4) code

CALL NLSGetLocale (lang, cntry, code) ! get all three
CALL NLSGetLocale (CODEPAGE = code) ! get the codepage
CALL NLSGetLocale (COUNTRY = cntry, CODEPAGE =code) ! get country

! and codepage

**See Also**

- M to N
- NLSSetLocale

*Building Applications: Locale Setting and Inquiry Routines*

**NLSGetLocaleInfo (W*32, W*64)**

**NLS Function:** Returns information about the current locale.

**Module**

USE IFNLS

**Syntax**

result = NLSGetLocaleInfo (type, outstr)

- type (Input) INTEGER(4). NLS parameter requested. A list of parameter names is provided in NLS LocaleInfo Parameters.

- outstr (Output) Character*(*) Character string. Parameter setting for the current locale. All parameter settings placed in outstr are character strings, even numbers. If a parameter setting is numeric, the ASCII representation of the number is used. If the requested parameter is a date or time string, an explanation of how to interpret the format in outstr is provided in NLS Date and Time Format.
Results

The result type is INTEGER(4). The result is the number of characters written to `outstr` if successful, or if `outstr` has 0 length, the number of characters required to hold the requested information. Otherwise, the result is one of the following error codes (defined in IFNLS.F90):

- **NLS$ErrorInvalidLIType** - The given `type` is invalid
- **NLS$ErrorInsufficientBuffer** - The `outstr` buffer was too small, but was not 0 (so that the needed size would be returned)

The NLS$LI parameters are used for the argument `type` and select the locale information returned by NLSGetLocaleInfo in `outstr`. You can perform an inclusive OR with NLS$NoUserOverride and any NLS$LI parameter. This causes NLSGetLocaleInfo to bypass any user overrides and always return the system default value.

The following table lists and describes the NLS$LI parameters.

**Table 856: NLS LocaleInfo Parameters**

<table>

6 - SDAYNAME7 | |
| NLS$LI_IFIRSTWEEKOFYEAR | Specifies which week of the year is considered first: |
| 0 - Week containing 1/1  
1 - First full week following 1/1  
2 - First week containing at least 4 days | |
| NLS$LI_SDAYNAME1 - NLS$LI_SDAYNAME7 | Native name for each day of the week. 1 = Monday, 2 = Tuesday, etc. |
| NLS$LI_SABBREVDAYNAME1 - NLS$LI_SABBREVDAYNAME7 | Native abbreviated name for each day of the week. 1 = Mon, 2 = Tue, etc. |
| NLS$LI_SMONTHNAME1 - NLS$LI_SMONTHNAME13 | Native name for each month. 1 = January, 2 = February, etc. 13 = the 13th month, if it exists in the locale. |
| NLS$LI_SABBREVMONTHNAME1 - NLS$LI_SABBREVMONTHNAME13 | Native abbreviated name for each month. 1 = Jan, 2 = Feb, etc. 13 = the 13th month, if it exists in the locale. |
When NLSGetLocaleInfo (type, outstr) returns information about the date and time formats of the current locale, the value returned in outstr can be interpreted according to the following tables. Any text returned within a date and time string that is enclosed within single quotes should be left in the string in its exact form; that is, do not change the text or the location within the string.

Day

The day can be displayed in one of four formats using the letter "d". The following table shows the four variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Day of the month as digits without leading zeros for single-digit days</td>
</tr>
<tr>
<td>dd</td>
<td>Day of the month as digits with leading zeros for single-digit days</td>
</tr>
<tr>
<td>ddd</td>
<td>Day of the week as a three-letter abbreviation (SABBREVDAYNAME)</td>
</tr>
<tr>
<td>dddd</td>
<td>Day of the week as its full name (SDAYNAME)</td>
</tr>
</tbody>
</table>

Month

The month can be displayed in one of four formats using the letter "M". The uppercase "M" distinguishes months from minutes. The following table shows the four variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>Month as digits without leading zeros for single-digit months</td>
</tr>
<tr>
<td>MM</td>
<td>Month as digits with leading zeros for single-digit months</td>
</tr>
<tr>
<td>MMM</td>
<td>Month as a three-letter abbreviation (SABBREVMONTHNAME)</td>
</tr>
<tr>
<td>MMMM</td>
<td>Month as its full name (SMONTHNAME)</td>
</tr>
</tbody>
</table>

Year

The year can be displayed in one of three formats using the letter "y". The following table shows the three variations:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>Year</td>
</tr>
<tr>
<td>yy</td>
<td>Year</td>

<tr>
<td>yy</td>
<td>Year represented by only the last two digits</td>
</tr>
<tr>
<td>yyyy</td>
<td>Year represented by the full 4 digits</td>
</tr>
</tbody>
</table>

**Period/Era**

The period/era string is displayed in a single format using the letters "gg".

<table>
<thead>
<tr>
<th>gg</th>
<th>Period/Era string</th>
</tr>
</thead>
</table>

**Time**

The time can be displayed in one of many formats using the letter "h" or "H" to denote hours, the letter "m" to denote minutes, the letter "s" to denote seconds and the letter "t" to denote the time marker. The following table shows the numerous variations of the time format. Lowercase "h" denotes the 12 hour clock and uppercase "H" denotes the 24 hour clock. The lowercase "m" distinguishes minutes from months.

<table>
<thead>
<tr>
<th>h</th>
<th>Hours without leading zeros for single-digit hours (12 hour clock)</th>

- NLSSetLocale

### NLSSetEnvironmentCodepage (W*32, W*64)

**NLS Function:** Sets the codepage for the current console. The specified codepage affects the current console program and any other programs launched from the same console. It does not affect other open consoles or any consoles opened later.

### Module

**USE IFNLS**
Syntax
result = NLSSetEnvironmentCodepage (codepage,flags)

codepage (Input) INTEGER(4). Number of the codepage to set as the console codepage.

flags (Input) INTEGER(4). Must be set to NLS$ConsoleEnvironmentCodepage.

Results
The result type is INTEGER(4). The result is zero if successful. Otherwise, returns one of the following error codes (defined in IFNLS.F90):

- NLS$ErrorInvalidCodepage - codepage is invalid or not installed on the system
- NLS$ErrorInvalidFlags - flags is not valid
- NLS$ErrorNoConsole - There is no console associated with the given application; so operations, with the console codepage are not possible

The flags argument must be NLS$ConsoleEnvironmentCodepage; it cannot be NLS$WindowsEnvironmentCodepage. NLSSetEnvironmentCodepage does not affect the Windows* codepage.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

- NLSSetEnvironmentCodepage

Building Applications: Locale Setting and Inquiry Routines

NLSSetLocale (W*32, W*64)
NLS Function: Sets the current language, country, or codepage.

Module
USE IFNLS
Syntax

result = NLSSetLocale (language[,country] [,codepage])

**language**
(Input) Character*(*). One of the languages supported by the Windows* OS NLS APIs.

**country**
(Input; optional) Character*(*). If specified, characterizes the language further. If omitted, the default country for the language is set.

**codepage**
(Input; optional) INTEGER(4). If specified, codepage to use for all character-oriented NLS functions. Can be any valid supported codepage or one of the following predefined values (defined in IFNLS.F90):

- NLS$CurrentCodepage - The codepage is not changed. Only the language and country settings are altered by the function.
- NLS$ConsoleEnvironmentCodepage - The codepage is changed to the default environment codepage currently in effect for console programs.
- NLS$ConsoleLanguageCodepage - The codepage is changed to the default console codepage for the language and country combination specified.
- NLS$WindowsEnvironmentCodepage - The codepage is changed to the default environment codepage currently in effect for Windows* OS programs.
- NLS$WindowsLanguageCodepage - The codepage is changed to the default Windows OS codepage for the language and country combination specified.

If you omit codepage, it defaults to NLS$WindowsLanguageCodepage. At program startup, NLS$WindowsEnvironmentCodepage is used to set the codepage.

Results

The result type is INTEGER(4). The result is zero if successful. Otherwise, one of the following error codes (defined in IFNLS.F90) may be returned:

- NLS$ErrorInvalidLanguage - language is invalid or not supported
- NLS$ErrorInvalidCountry - country is invalid or is not valid with the language specified
• NLS$ErrorInvalidCodepage - codepage is invalid or not installed on the system

**NOTE.** NLSSetLocale works on installed locales only. Many locales are supported, but they must be installed through the system Control Panel/International menu.

When doing mixed-language programming with Fortran and C, calling NLSSetLocale with a codepage other than the default environment Windows OS codepage causes the codepage in the C run-time library to change by calling C's setmbcp( ) routine with the new codepage. Conversely, changing the C run-time library codepage does not change the codepage in the Fortran NLS library.

Calling NLSSetLocale has no effect on the locale used by C programs. The locale set with C's setlocale( ) routine is independent of NLSSetLocale.

Calling NLSSetLocale with the default environment console codepage, NLS$ConsoleEnvironmentCodepage, causes an implicit call to the Windows OS API SetFileApisToOEM( ). Calling NLSSetLocale with any other codepage causes a call to SetFileApisToANSI( ).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**FREEFORM and NOFREEFORM**

**General Compiler Directives:** FREEFORM specifies that source code is in free-form format. NOFREEFORM specifies that source code is in fixed-form format.

**Syntax**

```plaintext
c $FREEFORM
nc $NOFREEFORM
```

`c` Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
When the FREEFORM or NOFREEFORM directives are used, they remain in effect for the remainder of the file, or until the opposite directive is used. When in effect, they apply to include files, but do not affect USE modules, which are compiled separately.

Building Applications: Compiler Directives Related to Options

**OPTIMIZE and NOOPTIMIZE**

*General Compiler Directive: Enables or disables optimizations.*

**Syntax**

```
cDEC$ OPTIMIZE[: n]
cDEC$ NOOPTIMIZE
```

- c Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- n Is the number denoting the optimization level. The number can be 0, 1, 2, or 3, which corresponds to compiler options O0, O1, O2, and O3. If n is omitted, the default is 2, which corresponds to option O2.

The OPTIMIZE and NOOPTIMIZE directives can only appear once at the top of a procedure program unit. A procedure program unit is a main program, an external subroutine or function, or a module. OPTIMIZE and NOOPTIMIZE cannot appear between program units or in a block data program unit. They do not affect any modules invoked with the USE statement in the program unit that contains them. They do affect CONTAINed procedures that do not include an explicit OPTIMIZE or NOOPTIMIZE directive.

NOOPTIMIZE is the same as OPTIMIZE:0. They are both equivalent to −O0 (Linux and Mac OS X) and /Od (Windows).
The procedure is compiled with an optimization level equal to the smaller of \( n \) and the optimization level specified by the O compiler option on the command line. For example, if the procedure contains the directive NOOPTIMIZE and the program is compiled with the O3 command line option, this procedure is compiled at O0 while the rest of the program is compiled at O3.

**See Also**
- M to N
- O to P
- General Compiler Directives
- O compiler option

**PREFETCH and NOPREFETCH**

**General Compiler Directives:** PREFETCH enables a data prefetch from memory. Prefetching data can minimize the effects of memory latency. NOPREFETCH (the default) disables data prefetching. These directives affect the heuristics used in the compiler.

**Syntax**

```fortran
$ c DEC$ PREFETCH [var1[: hint1[: distance1]] [,var2[: hint2[: distance2]]]...]
$ c DEC$ NOPREFETCH [var1[,var2]...]
```

- **c** Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- **var** Is an optional memory reference.
- **hint** Is an optional integer initialization expression with the value 0, 1, 2, or 3. These are the same as the values for hint in the intrinsic subroutine MM_PREFETCH. To use this argument, you must also specify var.
- **distance** Is an optional integer initialization expression with a value greater than 0. It indicates the number of loop iterations to perform before the prefetch. To use this argument, you must also specify var and hint.

To use these directives, compiler option O2 or O3 must be set.

This directive affects the DO loop it precedes.

If you specify PREFETCH with no arguments, all arrays accessed in the DO loop will be prefetched.
If a loop includes expression $A(j)$, placing `:DEC$ PREFETCH A` in front of the loop instructs the compiler to insert prefetches for $A(j + d)$ within the loop. The $d$ is determined by the compiler.

**Example**

cDEC$ NOPREFETCH c

cDEC$ PREFETCH a

do i = 1, m
  b(i) = a(c(i)) + 1
endo
The following example is valid on IA-64 architecture:

```
sum = 0.d0
do j = 1, lastrow - firstrow + 1
  i = rowstr(j)
  iresidue = mod( rowstr(j+1) - i, 8 )
  sum = 0.d0
  CDEC$ NOPREFETCH a, p, colidx
  do k = i, i + iresidue - 1
    sum = sum + a(k) * p(colidx(k))
  enddo
  CDEC$ NOPREFETCH colidx
  CDEC$ PREFETCH a:1:40
  CDEC$ PREFETCH p:1:20
  do k = i + iresidue, rowstr(j+1) - 8, 8
    sum = sum + a(k) * p(colidx(k))
    + a(k+1) * p(colidx(k+1)) + a(k+2) * p(colidx(k+2))
    + a(k+3) * p(colidx(k+3)) + a(k+4) * p(colidx(k+4))
    + a(k+5) * p(colidx(k+5)) + a(k+6) * p(colidx(k+6))
    + a(k+7) * p(colidx(k+7))
  enddo
  q(j) = sum
enddo
```

See Also

*Optimizing Applications*: Prefetching Support
**STRICT and NOSTRICT**

*General Compiler Directive:* **STRICT** disables language features not found in the language standard specified on the command line (Fortran 2003, Fortran 95, or Fortran 90). **NOSTRICT** (the default) enables these features.

**Syntax**

```
c DEC$ STRICT
```

```
c DEC$ NOSTRICT
```

Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

If **STRICT** is specified and no language standard is specified on the command line, the default is to disable features not found in Fortran 2003.

The **STRICT** and **NOSTRICT** directives can appear only at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. **STRICT** and **NOSTRICT** cannot appear between program units, or at the beginning of internal subprograms. They do not affect any modules invoked with the USE statement in the program unit that contains them.
Example

! NOSTRICT by default

TYPE stuff
  INTEGER(4) k
  INTEGER(4) m
  CHARACTER(4) name
END TYPE stuff

TYPE (stuff) examp
DOUBLE COMPLEX cd ! non-standard data type, no error
cd = (3.0D0, 4.0D0)
examp.k = 4 ! non-standard component designation,
            ! no error
END

SUBROUTINE STRICTDEMO( )
  !DEC$ STRICT
  TYPE stuff
    INTEGER(4) k
    INTEGER(4) m
    CHARACTER(4) name
  END TYPE stuff
  TYPE (stuff) samp
  DOUBLE COMPLEX cd ! ERROR
cd = (3.0D0, 4.0D0)
samp.k = 4 ! ERROR
END SUBROUTINE

**Building Applications**: Compiler Directives Related to Options

**SWP and NOSWP (i64 only)**

**General Compiler Directives**: SWP enables software pipelining for a DO loop. NOSWP (the default) disables this software pipelining. These directives are only available on IA-64 architecture.

**Syntax**

```c
DEC$ SWP
DEC$ NOSWP
```

Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

The SWP directive must precede the DO statement for each DO loop it affects.

The SWP directive does not help data dependence, but overrides heuristics based on profile counts or lop-sided control flow.

The software pipelining optimization specified by the SWP directive applies instruction scheduling to certain innermost loops, allowing instructions within a loop to be split into different stages.

This allows increased instruction level parallelism, which can reduce the impact of long-latency operations, resulting in faster loop execution.

Loops chosen for software pipelining are always innermost loops containing procedure calls that are inlined. Because the optimizer no longer considers fully unrolled loops as innermost loops, fully unrolling loops can allow an additional loop to become the innermost loop (see compiler option -funroll-loops or /Qunroll).

You can request and view the optimization report to see whether software pipelining was applied.
Example

!DEC$ SWP
    do i = 1, m
        if (a(i) .eq. 0) then
            b(i) = a(i) + 1
        else
            b(i) = a(i)/c(i)
        endif
    enddo

Optimizing Applications: Pipelining for Itanium®-based Architecture
Optimizing Applications: Optimizer Report Generation

NOT

Elemental Intrinsic Function (Generic):
Returns the logical complement of the argument.

Syntax

result = NOT (i)

i (Input) Must be of type integer.
Results

The result type is the same as \( i \). The result value is obtained by complementing \( i \) bit-by-bit according to the following truth table:

\[
\begin{array}{c|c}
I & \text{NOT}(I) \\
1 & 0 \\
0 & 1 \\
\end{array}
\]

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BNOT</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>INOT(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JNOT</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KNOT</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>
\(^1\)Or HNOT.

Example

If \( I \) has a value equal to 10101010 (base 2), \( \text{NOT}(I) \) has the value 01010101 (base 2).

The following shows another example:

```
INTEGER(2) i(2), j(2)
i = (/4, 132/)
! i(1) = 0000000000000100
! i(2) = 0000000010000100
j = NOT(i)
! returns (-5,-133)
! j(1) = 1111111111111011
! j(2) = 111111101111011
```

See Also

- M to N
- BTEST
UNROLL and NOUNROLL

**General Compiler Directive:** Tells the compiler’s optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop. These directives can only be applied to iterative DO loops.

**Syntax**
```
c DEC$ UNROLL [(n)] -or- c DEC$ UNROLL [=n]
c DEC$ NOUNROLL
```

- **c**
  Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

- **n**
  Is an integer constant. The range of n is 0 through 255.

If **n** is specified, the optimizer unrolls the loop **n** times. If **n** is omitted, or if it is outside the allowed range, the optimizer picks the number of times to unroll the loop.

The UNROLL directive overrides any setting of loop unrolling from the command line.

To use these directives, compiler option O2 or O3 must be set.
Example

cDEC$ UNROLL

do i = 1, m
   b(i) = a(i) + 1
   d(i) = c(i) + 1
endo

VECTOR ALWAYS and NOVECTOR

*General Compiler Directive: Enables or disables vectorization of a DO loop.*

**Syntax**

cDEC$ VECTOR ALWAYS

cDEC$ NOVECTOR

c The vectorization directive.

Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

The VECTOR ALWAYS and NOVECTOR directives override the default behavior of the compiler. The VECTOR ALWAYS directive also overrides efficiency heuristics of the vectorizer, but it only works if the loop can actually be vectorized. You should use the IVDEP directive to ignore assumed dependences.

**CAUTION.** The directive VECTOR ALWAYS should be used with care. Overriding the efficiency heuristics of the compiler should only be done if you are absolutely sure the vectorization will improve performance.
Example

The compiler normally does not vectorize DO loops that have a large number of non-unit stride references (compared to the number of unit stride references).

In the following example, vectorization would be disabled by default, but the directive overrides this behavior:

```fortran
!DEC$ VECTOR ALWAYS
    do i = 1, 100, 2
        ! two references with stride 2 follow
        a(i) = b(i)
    enddo
```

There may be cases where you want to explicitly avoid vectorization of a loop; for example, if vectorization would result in a performance regression rather than an improvement. In these cases, you can use the NOVECTOR directive to disable vectorization of the loop.

In the following example, vectorization would be performed by default, but the directive overrides this behavior:

```fortran
!DEC$ NOVECTOR
    do i = 1, 100
        a(i) = b(i) + c(i)
    enddo
```

- M to N
- T to Z
- Rules for General Directives that Affect DO Loops

NULL

Transformational Intrinsic Function (Generic):
Initializes a pointer as disassociated when it is declared. This is a new intrinsic function in Fortran 95.

Syntax

```fortran
result = NULL ([ mold])
```
**mold** (Optional) Must be a pointer; it can be of any type. Its pointer association status can be associated, disassociated, or undefined. If its status is associated, the target does not have to be defined with a value.

**Results**
The result type is the same as *mold*, if present; otherwise, it is determined as follows:

<table>
<thead>
<tr>
<th>If NULL ( ) Appears...</th>
<th>Type is Determined From...</th>
</tr>
</thead>
<tbody>
<tr>
<td>On the right side of pointer assignment</td>
<td>The pointer on the left side</td>
</tr>
<tr>
<td>As initialization for an object in a declaration</td>
<td>The object</td>
</tr>
<tr>
<td>As default initialization for a component</td>
<td>The component</td>
</tr>
<tr>
<td>In a structure constructor</td>
<td>The corresponding component</td>
</tr>
<tr>
<td>As an actual argument</td>
<td>The corresponding dummy argument</td>
</tr>
<tr>
<td>In a DATA statement</td>
<td>The corresponding pointer object</td>
</tr>
</tbody>
</table>

The result is a pointer with disassociated association status.

**CAUTION.** If you use module IFWIN or IFWINTY, you will have a name conflict if you use the NULL intrinsic. To avoid this problem, rename the integer parameter constant NULL to something else; for example:

```fortran
USE IFWIN, NULL0 => NULL
```

This example lets you use both NULL0 and NULL( ) in the same program unit with no conflict.

**Example**
Consider the following:

```fortran
INTEGER, POINTER :: POINT1 => NULL( )
```

This statement defines the initial association status of POINT1 to be disassociated.
**NULLIFY**

*Statement:* Disassociates a pointer from a target.

**Syntax**

```fortran
NULLIFY (pointer-object[, pointer-object]...)
```

*pointer-object*  Is a structure component or the name of a variable; it must be a pointer (have the POINTER attribute).

**Description**

The initial association status of a pointer is undefined. You can use NULLIFY to initialize an undefined pointer, giving it disassociated status. Then the pointer can be tested using the intrinsic function ASSOCIATED.

**Example**

The following is an example of the NULLIFY statement:

```fortran
REAL, TARGET :: TAR(0:50)
REAL, POINTER :: PTR_A(:), PTR_B(:)
PTR_A => TAR
PTR_B => TAR
...
NULLIFY(PTR_A)
```

After these statements are executed, PTR_A will have disassociated status, while PTR_B will continue to be associated with variable TAR.
The following shows another example:

```fortran
! POINTER2.F90  Pointing at a Pointer and Target

!DEC$ FIXEDFORMLINESIZE:80

REAL, POINTER :: arrow1(:)
REAL, POINTER :: arrow2(:)
REAL, ALLOCATABLE, TARGET :: bullseye(:)
ALLOCATE (bullseye (7))
bullseye = 1.
bullseye (1:7:2) = 10.
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye
arrow1 => bullseye
WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow1
arrow2 => arrow1
IF (ASSOCIATED(arrow2)) WRITE (*,'(/a/)') ' ARROW2 is pointed.'
WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow2
NULLIFY (arrow2)
IF (.NOT.ASSOCIATED(arrow2)) WRITE (*,'(/a/)') ' ARROW2 is not pointed.'
WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow1
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye
END
```

OBJCOMMENT

Syntax

cDEC$ OBJCOMMENT LIB: library

- c: Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- library: Is a character constant specifying the name and, if necessary, the path of the library that the linker is to search.

The linker searches for the library named in OBJCOMMENT as if you named it on the command line, that is, before default library searches. You can place multiple library search directives in the same source file. Each search directive appears in the object file in the order it is encountered in the source file.

If the OBJCOMMENT directive appears in the scope of a module, any program unit that uses the module also contains the directive, just as if the OBJCOMMENT directive appeared in the source file using the module.

If you want to have the OBJCOMMENT directive in a module, but do not want it in the program units that use the module, place the directive outside the module that is used.
Example

! MOD1.F90

MODULE a
  !DEC$ OBJCOMMENT LIB: "opengl32.lib"
END MODULE a

! MOD2.F90

!DEC$ OBJCOMMENT LIB: "graftools.lib"
MODULE b
  !
END MODULE b

! USER.F90

PROGRAM go
  USE a ! library search contained in MODULE a
    ! included here
  USE b ! library search not included
END

Building Applications: Compiler Directives Related to Options

OPEN

Statement: Connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection.

Syntax

OPEN ([UNIT=] io-unit[, FILE= name] [, ERR= label] [, IOSTAT=i-var], slist)

io-unit          Is an external unit specifier.
name  Is a character or numeric expression specifying the name of the file to be connected. For more information, see FILE Specifier and STATUS Specifier.

label  Is the label of the branch target statement that receives control if an error occurs. For more information, see Branch Specifiers.

i-var  Is a scalar integer variable that is defined as a positive integer (the number of the error message) if an error occurs, a negative integer if an end-of-file record is encountered, and zero if no error occurs. For more information, see I/O Status Specifier.

slist  Is one or more of the following OPEN specifiers in the form specifier= value or specifier (each specifier can appear only once):

- ACCESS
- CARTRIDGECONTROL
- MAXREC
- RECORDSIZE
- ACTION
- CONVERT
- MODE
- RECORDTYPE
- ASSOCIATE
- VARIABLE
- DEFAULTFILE
- NAME
- SHARE
- ASYNCHRONOUS
- DELIM
- ORGANIZATION
- SHARED
- BLANK
- DISPOSE
- PAD
- STATUS
- BLOCKSIZE
- FILE
- POSITION
- TITLE
- BUFFERCOUNT
- FORM
- READONLY
- TYPE
- BUFFERED
- IOFOCUS
- RECL
- USEROPEN

The OPEN specifiers and their acceptable values are summarized in the OPEN Statement in the Language Reference. The control specifiers that can be specified in an OPEN statement are discussed in I/O Control List in the Language Reference.

Description

The control specifiers ([UNIT=] io-unit, ERR= label, and IOSTAT= i-var) and OPEN specifiers can appear anywhere within the parentheses following OPEN. However, if the UNIT specifier is omitted, the io-unit must appear first in the list.

Specifier values that are scalar numeric expressions can be any integer or real expression. The value of the expression is converted to integer data type before it is used in the OPEN statement.
Only one unit at a time can be connected to a file, but multiple OPENs can be performed on the same unit. If an OPEN statement is executed for a unit that already exists, the following occurs:

- If FILE is not specified, or FILE specifies the same file name that appeared in a previous OPEN statement, the current file remains connected. If the file names are the same, the values for the BLANK, CARRIAGECONTROL, CONVERT, DELIM, DISPOSE, ERR, IOSTAT, and PAD specifiers can be changed. Other OPEN specifier values cannot be changed, and the file position is unaffected.
- If FILE specifies a different file name, the previous file is closed and the new file is connected to the unit.

The ERR and IOSTAT specifiers from any previously executed OPEN statement have no effect on any currently executing OPEN statement. If an error occurs, no file is opened or created. Secondary operating system messages do not display when IOSTAT is specified. To display these messages, remove IOSTAT or use a platform-specific method.

**Example**

You can specify character values at run time by substituting a character expression for a specifier value in the OPEN statement. The character value can contain trailing blanks but not leading or embedded blanks, for example:

```fortran
character*6 FINAL /' '/
...
if (expr) FINAL = 'DELETE'
open (unit=1, status='NEW', disp=FINAL)
```

The following statement creates a new sequential formatted file on unit 1 with the default file name fort.1:

```fortran
open (unit=1, status='NEW', err=100)
```

The following statement creates a file on magnetic tape:

```fortran
open (unit=1, file='/dev/rmt8',
     status='NEW', err=14, recl=1024)
```

The following statement opens the file (created in the previous example) for input:

```fortran
open (unit=1, file='/dev/rmt8', readonly, status='OLD',
      recl=1024)
The following example opens the existing file /usr/users/someone/test.dat:

```fortran
OPEN (unit=10, DEFAULTFILE='usr/users/someone/', FILE='test.dat',
     1 FORM='FORMATTED', STATUS='OLD')
```

The following example opens a new file:

```fortran
! Prompt user for a filename and read it:
CHARACTER*64 filename
WRITE (*, '(A)') ' enter file to create: '
READ (*, '(A)') filename
! Open the file for formatted sequential access as unit 7.
! Note that the specified access need not have been specified,
! since it is the default (as is "formatted").
OPEN (7, FILE = filename, ACCESS = 'SEQUENTIAL', STATUS = 'NEW')
```

The following example opens an existing file called DATA3.TXT:

```fortran
! Open a file created by an editor, "DATA3.TXT", as unit 3:
OPEN (3, FILE = 'DATA3.TXT')
```

**OPTIONAL**

**Statement and Attribute:** Permits dummy arguments to be omitted in a procedure reference.

**Syntax**

The OPTIONAL attribute can be specified in a type declaration statement or an OPTIONAL statement, and takes one of the following forms:
Type Declaration Statement:

\[
\text{type},[\text{att-}\text{ls}],\text{OPTIONAL } [, \text{att-}\text{ls}] :: d-\text{arg}[, \text{d-arg}]... \\
\text{Statement:}
\]

OPTIONAL [::] d-\text{arg}[, \text{d-arg}] ...

\begin{itemize}
\item \text{\textit{type}} \quad \text{Is a data type specifier.}
\item \text{\textit{att-}\text{ls}} \quad \text{Is an optional list of attribute specifiers.}
\item \text{\textit{d-arg}} \quad \text{Is the name of a dummy argument.}
\end{itemize}

Description

The OPTIONAL attribute can only appear in the scoping unit of a subprogram or an interface body, and can only be specified for dummy arguments. It cannot be specified for arguments that are passed by value.

A dummy argument is "present" if it associated with an actual argument. A dummy argument that is not optional must be present. You can use the PRESENT intrinsic function to determine whether an optional dummy argument is associated with an actual argument.

To call a procedure that has an optional argument, you must use an explicit interface.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments. A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

Example

The following example shows a type declaration statement specifying the OPTIONAL attribute:

```
SUBROUTINE TEST(A)
  REAL, OPTIONAL, DIMENSION(-10:2) :: A
END SUBROUTINE
```
The following is an example of the OPTIONAL statement:

```fortran
SUBROUTINE TEST(A, B, L, X)
  OPTIONAL :: B
  INTEGER A, B, L, X
  IF (PRESENT(B)) THEN ! Printing of B is conditional
    PRINT *, A, B, L, X ! on its presence
  ELSE
    PRINT *, A, L, X
  ENDIF
END SUBROUTINE

INTERFACE
  SUBROUTINE TEST(ONE, TWO, THREE, FOUR)
    INTEGER ONE, TWO, THREE, FOUR
    OPTIONAL :: TWO
  END SUBROUTINE
END INTERFACE

INTEGER I, J, K, L
I = 1
J = 2
K = 3
L = 4
CALL TEST(I, J, K, L) ! Prints: 1 2 3 4
CALL TEST(I, THREE=K, FOUR=L) ! Prints: 1 3 4
END
```

Note that in the second call to subroutine TEST, the second positional (optional) argument is omitted. In this case, all following arguments must be keyword arguments.
The following shows another example:

```fortran
SUBROUTINE ADD (a,b,c,d)
    REAL a, b, d
    REAL, OPTIONAL :: c
    IF (PRESENT(c)) THEN
        d = a + b + c + d
    ELSE
        d = a + b + d
    END IF
END SUBROUTINE
```

Consider the following:

```fortran
SUBROUTINE EX (a, b, c)
    REAL, OPTIONAL :: b,c

This subroutine can be called with any of the following statements:

CALL EX (x, y, z)  !All 3 arguments are passed.
CALL EX (x)        !Only the first argument is passed.
CALL EX (x, c=z)   !The first optional argument is omitted.
```

Note that you cannot use a series of commas to indicate omitted optional arguments, as in the following example:

```fortran
CALL EX (x,,z)    !Invalid statement.
```

This results in a compile-time error.

**OPTIONS Statement**

*Statement:* Overrides or confirms the compiler options in effect for a program unit.

**Syntax**

```
OPTIONS option[option...]
```

<table>
<thead>
<tr>
<th>option</th>
<th>Is one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ASSUME =</td>
<td>[NO]UNDERSCORE</td>
</tr>
<tr>
<td>/CHECK =</td>
<td>ALL</td>
</tr>
<tr>
<td></td>
<td>[NO]BOUNDS</td>
</tr>
<tr>
<td></td>
<td>NONE</td>
</tr>
<tr>
<td>/NOCHECK</td>
<td></td>
</tr>
<tr>
<td>/CONVERT =</td>
<td>BIG_ENDIAN</td>
</tr>
<tr>
<td></td>
<td>CRAY</td>
</tr>
<tr>
<td></td>
<td>FDX</td>
</tr>
<tr>
<td></td>
<td>FGX</td>
</tr>
<tr>
<td></td>
<td>IBM</td>
</tr>
<tr>
<td></td>
<td>LITTLE_ENDIAN</td>
</tr>
<tr>
<td></td>
<td>NATIVE</td>
</tr>
<tr>
<td></td>
<td>VAXD</td>
</tr>
<tr>
<td></td>
<td>VAXG</td>
</tr>
<tr>
<td>/[NO]EXTEND_SOURCE</td>
<td></td>
</tr>
<tr>
<td>/[NO]F77</td>
<td></td>
</tr>
<tr>
<td>/[NO]I4</td>
<td></td>
</tr>
<tr>
<td>/[NO]RECURSIVE</td>
<td></td>
</tr>
</tbody>
</table>

Note that an option must always be preceded by a slash (/).
Some OPTIONS statement options are equivalent to compiler options.

The OPTIONS statement must be the first statement in a program unit, preceding the PROGRAM, SUBROUTINE, FUNCTION, MODULE, and BLOCK DATA statements.

OPTIONS statement options override compiler options, but only until the end of the program unit for which they are defined. If you want to override compiler options in another program unit, you must specify the OPTIONS statement before that program unit.

**Example**

The following are valid OPTIONS statements:

```plaintext
OPTIONS /CHECK=ALL/F77
OPTIONS /I4
```

**See Also**

- O to P

For details on compiler options, see your Compiler Options reference

*Building Applications: OPEN Statement CONVERT Method*

**OPTIMIZE and NOOPTIMIZE**

**General Compiler Directive:** Enables or disables optimizations.

**Syntax**

```plaintext
cDEC$ OPTIMIZE[, n]
cDEC$ NOOPTIMIZE
```

- `c` Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- `n` Is the number denoting the optimization level. The number can be 0, 1, 2, or 3, which corresponds to compiler options O0, O1, O2, and O3. If `n` is omitted, the default is 2, which corresponds to option O2.

The OPTIMIZE and NOOPTIMIZE directives can only appear once at the top of a procedure program unit. A procedure program unit is a main program, an external subroutine or function, or a module. OPTIMIZE and NOOPTIMIZE cannot appear between program units or in a block.
data program unit. They do not affect any modules invoked with the USE statement in the program unit that contains them. They do affect CONTAINed procedures that do not include an explicit OPTIMIZE or NOOPTIMIZE directive.

NOOPTIMIZE is the same as OPTIMIZE:0. They are both equivalent to −O0 (Linux and Mac OS X) and /Od (Windows).

The procedure is compiled with an optimization level equal to the smaller of $n$ and the optimization level specified by the O compiler option on the command line. For example, if the procedure contains the directive NOOPTIMIZE and the program is compiled with the O3 command line option, this procedure is compiled at O0 while the rest of the program is compiled at O3.

**See Also**
- M to N
- O to P
- General Compiler Directives
- O compiler option

**OPTIONS Directive**

*General Compiler Directive: Affects data alignment and warnings about data alignment.*

**Syntax**

```plaintext
CDEC$ OPTIONS option[option]
...
CDEC$ END OPTIONS
```

- **c**
  - Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- **option**
  - Is one (or both) of the following:
    - `/WARN=[NO]ALIGNMENT` Controls whether warnings are issued by the compiler for data that is not naturally aligned. By default, you receive compiler messages when misaligned data is encountered (`/WARN=ALIGNMENT`).
    - `/[NO]ALIGN [= p]` Controls alignment of fields in record structures and data items in common blocks. The fields and data items can be naturally
aligned (for performance reasons) or they can be packed together on arbitrary byte boundaries.

\[ p \]

Is a specifier with one of the following forms:

\[ \text{[class=} \text{rule} \]

\[ \text{(class=} \text{rule},...) \]

\[ \text{ALL} \]

\[ \text{NONE} \]

\[ \text{class} \]

Is one of the following keywords:

- \text{COMMONS}: For common blocks
- \text{RECORDS}: For records
- \text{STRUCTURES}: A synonym for \text{RECORDS}

\[ \text{rule} \]

Is one of the following keywords:

- \text{PACKED}: Packs fields in records or data items in common blocks on arbitrary byte boundaries.
- \text{NATURAL}: Naturally aligns fields in records and data items in common blocks on up to
64-bit boundaries (inconsistent with the Fortran 95/90 standard). This keyword causes the compiler to naturally align all data in a common block, including `INTEGER(KIND=8)`, `REAL(KIND=8)`, and all `COMPLEX` data.

**STANDARD**: Naturally aligns data items in common blocks on up to 32-bit boundaries (consistent with the Fortran 95/90 standard). This keyword only applies to common blocks; so, you can specify `/ALIGN=COMMON=STANDARD` but you cannot specify `/ALIGN=STANDARD.`
<table>
<thead>
<tr>
<th>ALL</th>
<th>Is the same as specifying OPTIONS /ALIGN, OPTIONS /ALIGN=NATURAL, and OPTIONS /ALIGN=(RECORDS=NATURAL, COMMONS=NATURAL).</th>
</tr>
</thead>
<tbody>
<tr>
<td>NONE</td>
<td>Is the same as specifying OPTIONS /NOALIGN, OPTIONS /ALIGN=PACKED, and OPTIONS /ALIGN=(RECORDS=PACKED, COMMONS=PACKED).</td>
</tr>
</tbody>
</table>

The OPTIONS (and accompanying END OPTIONS) directives must come after OPTIONS, SUBROUTINE, FUNCTION, and BLOCK DATA statements (if any) in the program unit, and before the executable part of the program unit.

The OPTIONS directive supersedes compiler option align.

For performance reasons, Intel Fortran aligns local data items on natural boundaries. However, EQUIVALENCE, COMMON, RECORD, and STRUCTURE data declaration statements can force misaligned data. If /WARN=NOALIGNMENT is specified, warnings will not be issued if misaligned data is encountered.

**NOTE.** Misaligned data significantly increases the time it takes to execute a program. As the number of misaligned fields encountered increases, so does the time needed to complete program execution. Specifying /ALIGN (or compiler option align) minimizes misaligned data.

If you want aligned data in common blocks, do one of the following:

- Specify OPTIONS /ALIGN=COMMONS=STANDARD for data items up to 32 bits in length.
- Specify OPTIONS /ALIGN=COMMONS=NATURAL for data items up to 64 bits in length.
- Place source data declarations within the common block in descending size order, so that each data item is naturally aligned.

If you want packed, unaligned data in a record structure, do one of the following:

- Specify OPTIONS /ALIGN=RECORDS=PACKED.
Place source data declarations in the record structure so that the data is naturally aligned.

Example

! directives can be nested up to 100 levels
CDEC$ OPTIONS /ALIGN=PACKED   ! Start of Group A
   declarations
CDEC$ OPTIONS /ALIGN=RECO=NATU ! Start of nested Group B
   more declarations
CDEC$ END OPTIONS             ! End of Group B
   still more declarations
CDEC$ END OPTIONS             ! End of Group A

The OPTIONS specification for Group B only applies to RECORDS; common blocks within Group B will be PACKED. This is because COMMONS retains the previous setting (in this case, from the Group A specification).

- O to P
- General Compiler Directives
- align compiler option

OR

Elemental Intrinsic Function (Generic): Performs a bitwise inclusive OR on its arguments. See IOR.

Example

INTEGER i
i = OR(3, 10)     ! returns 11
ORDERED

OpenMP Fortran Compiler Directive: Specifies a block of code to be executed in the order in which iterations would be executed in sequential execution.

Syntax

\texttt{c$OMP \textbf{ORDERED}}

\texttt{block}

\texttt{c$OMP \textbf{ORDERED}}

\texttt{c}

Is one of the following: \texttt{C} (or \texttt{c}), \texttt{!}, or \texttt{*} (see Syntax Rules for Compiler Directives).

\texttt{block}

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

An ORDERED directive can appear only in the dynamic extent of a \texttt{DO} or \texttt{PARALLEL DO} directive. The \texttt{DO} directive to which the ordered section binds must have the ORDERED clause specified.

An iteration of a loop using a \texttt{DO} directive must not execute the same ORDERED directive more than once, and it must not execute more than one ORDERED directive.

One thread is allowed in an ordered section at a time. Threads are allowed to enter in the order of the loop iterations. No thread can enter an ordered section until it can be guaranteed that all previous iterations have completed or will never execute an ordered section. This sequentializes and orders code within ordered sections while allowing code outside the section to run in parallel.

Ordered sections that bind to different \texttt{DO} directives are independent of each other.
Example
Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```fortran
C$OMP DO ORDERED SCHEDULE(DYNAMIC)
  DO I=LB,UB,ST
    CALL WORK(I)
  END DO
...
SUBROUTINE WORK(K)
C$OMP ORDERED
  WRITE(*,*) K
C$OMP END ORDERED
```

- OpenMP Fortran Compiler Directives

OUTGTEXT (W*32, W*64)

**Graphics Subroutine:** In graphics mode, sends a string of text to the screen, including any trailing blanks.

Module
USE IFQWIN

Syntax
CALL OUTGTEXT (text)

**text** (Input) Character*(*) String to be displayed.

Text output begins at the current graphics position, using the current font set with SETFONT and the current color set with SETCOLORRGB or SETCOLOR. No formatting is provided. After it outputs the text, OUTGTEXT updates the current graphics position.

Before you call OUTGTEXT, you must call the INITIALIZEFONTS function.
Because OUTGTEXT is a graphics function, the color of text is affected by the SETCOLORRGB function, not by SETTEXTCOLORRGB.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! build as a QuickWin App.

USE IFQWIN

INTEGER(2) result
INTEGER(4) i

TYPE (xycoord) xys

result = INITIALIZEFONTS()
result = SETFONT('t''Arial''h18w10pvib')
do i=1,6
    CALL MOVETO(INT2(0),INT2(30*(i-1)),xys)
    grstat=SETCOLOR(INT2(i))
    CALL OUTGTEXT('This should be ')
    SELECT CASE (i)
    CASE (1)
        CALL OUTGTEXT('Blue')
    CASE (2)
        CALL OUTGTEXT('Green')
    CASE (3)
        CALL OUTGTEXT('Cyan')
    CASE (4)
        CALL OUTGTEXT('Red')
    CASE (5)
        CALL OUTGTEXT('Magenta')
    CASE (6)
        CALL OUTGTEXT('Orange')
    END SELECT
end do

END

Building Applications: Setting Figure Properties
Building Applications: Selecting Display Options

OUTTEXT (W*32, W*64)

Graphics Subroutine: In text or graphics mode, sends a string of text to the screen, including any trailing blanks.

Module
USE IFQWIN

Syntax
CALL OUTTEXT (text)

(text) (Input) Character*(*) String to be displayed.

Text output begins at the current text position in the color set with SETTEXTCOLORRGB or SETTEXTCOLOR. No formatting is provided. After it outputs the text, OUTTEXT updates the current text position.

To output text using special fonts, you must use the OUTGTEXT subroutine.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

USE IFQWIN

INTEGER(2) oldcolor
TYPE (rccoord) rc
CALL CLEARSCREEN($GCLEARSCREEN)
CALL SETTEXTPOSITION (INT2(1), INT2(5), rc)
oldcolor = SETTEXTCOLOR(INT2(4))
CALL OUTTEXT ('Hello, everyone')
END

Building Applications: Displaying Character-Based Text
Building Applications: Using Text Colors

PACK Function

Transformational Intrinsic Function (Generic):
Takes elements from an array and packs them into a rank-one array under the control of a mask.

Syntax

result = PACK (array, mask[, vector])

array (Input) Must be an array. It may be of any data type.
mask (Input) Must be of type logical and conformable with array. It determines which elements are taken from array.
vector

(Input; optional) Must be a rank-one array with the same type and type parameters as array. Its size must be at least $t$, where $t$ is the number of true elements in mask. If mask is a scalar with value true, vector must have at least as many elements as there are in array. Elements in vector are used to fill out the result array if there are not enough elements selected by mask.

Results

The result is a rank-one array with the same type and type parameters as array. If vector is present, the size of the result is that of vector. Otherwise, the size of the result is the number of true elements in mask, or the number of elements in array (if mask is a scalar with value true).

Elements in array are processed in array element order to form the result array. Element i of the result is the element of array that corresponds to the ith true element of mask. If vector is present and has more elements than there are true values in mask, any result elements that are empty (because they were not true according to mask) are set to the corresponding values in vector.

Example

N is the array

\[
\begin{pmatrix}
0 & 8 & 0 \\
0 & 0 & 0 \\
7 & 0 & 0 \\
\end{pmatrix}
\]

PACK (N, MASK=N .NE. 0, VECTOR=(/1, 3, 5, 9, 11, 13/)) produces the result (7, 8, 5, 9, 11, 13).

PACK (N, MASK=N .NE. 0) produces the result (7, 8).
The following shows another example:

```fortran
INTEGER array(2, 3), vec1(2), vec2(5)
LOGICAL mask (2, 3)
array = RESHAPE((/7, 0, 0, -5, 0, 0/), (/2, 3/))
mask = array .NE. 0
! array is 7 0 0 and mask is T F F
! -5 0 0 F T F
VEC1 = PACK(array, mask) ! returns ( 7, -5 )
VEC2 = PACK(array, array .GT. 0, VECTOR= (/1,2,3,4,5/))
! returns ( 7, 2, 3, 4, 5 )
```

PACK Directive

**General Compiler Directive:** Specifies the memory starting addresses of derived-type items (and record structure items).

**Syntax**

```fortran
$ PACK[: [1 | 2 | 4 | 8]] ]
```

- `c` is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

Items of derived types, unions, and structures are aligned in memory on the smaller of two sizes: the size of the type of the item, or the current alignment setting. The current alignment setting can be 1, 2, 4, or 8 bytes. The default initial setting is 8 bytes (unless compiler option vms or align rec n bytes is specified). By reducing the alignment setting, you can pack variables closer together in memory.

The PACK directive lets you control the packing of derived-type or record structure items inside your program by overriding the current memory alignment setting.
For example, if PACK:1 is specified, all variables begin at the next available byte, whether odd or even. Although this slightly increases access time, no memory space is wasted. If PACK:4 is specified, INTEGER(1), LOGICAL(1), and all character variables begin at the next available byte, whether odd or even. INTEGER(2) and LOGICAL(2) begin on the next even byte; all other variables begin on 4-byte boundaries.

If the PACK directive is specified without a number, packing reverts to the compiler option setting (if any), or the default setting of 8.

The directive can appear anywhere in a program before the derived-type definition or record structure definition. It cannot appear inside a derived-type or record structure definition.

**Example**

```fortran
! Use 4-byte packing for this derived type
! Note PACK is used outside of the derived type definition
!DEC$ PACK:4
TYPE pair
  INTEGER a, b
END TYPE
! revert to default or compiler option
!DEC$ PACK
```

*Building Applications: Compiler Directives Related to Options*
PACKTIMEQQ

Portability Subroutine: Packs time and date values.

Module
USE IFPORT

Syntax
CALL PACKTIMEQQ (timedate, iyr, imon, iday, ihr, imin, isec)

timedate      (Output) INTEGER(4). Packed time and date information.
iyr           (Input) INTEGER(2). Year (xxxxAD).
imon          (Input) INTEGER(2). Month (1 - 12).
iday          (Input) INTEGER(2). Day (1 - 31)
ihr            (Input) INTEGER(2). Hour (0 - 23)
imin          (Input) INTEGER(2). Minute (0 - 59)
isec          (Input) INTEGER(2). Second (0 - 59)

The packed time is the number of seconds since 00:00:00 Greenwich mean time, January 1, 1970. Because packed time values can be numerically compared, you can use PACKTIMEQQ to work with relative date and time values. Use UNPACKTIMEQQ to unpack time information. SETFILETIMEQQ uses packed time.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS DLL LIB
Example

USE IFPORT

INTEGER(2) year, month, day, hour, minute, second, &
hund
INTEGER(4) timedate
CALL GETDAT (year, month, day)
CALL GETTIM (hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, hour, &
minute, second)
END

PARALLEL Directive (OpenMP*)

OpenMP* Fortran Compiler Directive: Defines a parallel region.

Syntax

\$OMP PARALLEL [clause[, clause] ... ]
   block
\$OMP END PARALLEL

\$ Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

clause

Is one of the following:

- COPYIN (list)
- DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
- FIRSTPRIVATE (list)
• IF (scalar_logical_expression)
  Specifies that the enclosed code section is to be executed in parallel only if the scalar_logical_expression evaluates to .TRUE.. Otherwise, the parallel region is serialized. If this clause is not used, the region is executed as if an IF(.TRUE.) clause were specified.
  This clause is evaluated by the master thread before any data scope attributes take effect.
  Only a single IF clause can appear in the directive.

• NUM_THREADS (scalar_integer_expression)
  Specifies the number of threads to be used in a parallel region. The scalar_integer_expression must evaluate to a positive scalar integer value. Only a single NUM_THREADS clause can appear in the directive.
  • PRIVATE (list)
  • REDUCTION (operator | intrinsic : list)
  • SHARED (list)

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).

The PARALLEL and END PARALLEL directive pair must appear in the same routine in the executable section of the code.

The END PARALLEL directive denotes the end of the parallel region. There is an implied barrier at this point. Only the master thread of the team continues execution at the end of a parallel region.

The number of threads in the team can be controlled by the NUM_THREADS clause, the environment variable OMP_NUM_THREADS, or by calling the run-time library routine OMP_SET_NUM_THREADS from a serial portion of the program.

NUM_THREADS supersedes the OMP_SET_NUM_THREADS routine, which supersedes the OMP_NUM_THREADS environment variable. Subsequent parallel regions, however, are not affected unless they have their own NUM_THREADS clauses.

Once specified, the number of threads in the team remains constant for the duration of that parallel region.
If the dynamic threads mechanism is enabled by an environment variable or a library routine, then the number of threads requested by the NUM_THREADS clause is the maximum number to use in the parallel region.

The code contained within the dynamic extent of the parallel region is executed on each thread, and the code path can be different for different threads.

If a thread executing a parallel region encounters another parallel region, it creates a new team and becomes the master of that new team. By default, nested parallel regions are always serialized and executed by a team of one thread.

Example

You can use the PARALLEL directive in coarse-grain parallel programs. In the following example, each thread in the parallel region decides what part of the global array X upon which to work based on the thread number:

```c
C$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,NPOINTS)
    IAM = OMP_GET_THREAD_NUM()
    NP = OMP_GET_NUM_THREADS()
    IPOINTS = NPOINTS/NP
    CALL SUBDOMAIN(X,IAM,IPOINTS)
C$OMP END PARALLEL
```

Assuming you previously used the environment variable OMP_NUM_THREADS to set the number of threads to six, you can change the number of threads between parallel regions as follows:

```c
CALL OMP_SET_NUM_THREADS(3)
!$OMP PARALLEL
...
!$OMP END PARALLEL
CALL OMP_SET_NUM_THREADS(4)
!$OMP PARALLEL DO
...
!$OMP END PARALLEL DO
```

For more information on environment variables, see *Building Applications*.
PARALLEL and NOPARALLEL Loop Directives

**General Compiler Directives:** PARALLEL facilitates auto-parallelization for the immediately following DO loop. NOPARALLEL prevents this auto-parallelization.

**Syntax**

```c
DEC$ PARALLEL [ALWAYS]
```

```c
DEC$ NOPARALLEL
```

Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

PARALLEL helps the compiler to resolve dependencies, facilitating auto-parallelization of the immediately following DO loop. It instructs the compiler to ignore dependencies that it assumes may exist and which would prevent correct parallelization in the loop. However, if dependencies are proven, they are not ignored.

In addition, PARALLEL ALWAYS overrides the compiler heuristics that estimate the likelihood that parallelization of a loop will increase performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance.

NOPARALLEL prevents auto-parallelization of the immediately following DO loop.

These directives take effect only if you specify the compiler option that enables auto-parallelization.

**CAUTION.** The directive PARALLEL ALWAYS should be used with care. Overriding the heuristics of the compiler should only be done if you are absolutely sure the parallelization will improve performance.
Example

program main
parameter (n=100)
integer x(n),a(n)
!DEC$ NOPARALLEL
    do i=1,n
        x(i) = i
    enddo
!DEC$ PARALLEL
    do i=1,n
        a( x(i) ) = i
    enddo
end

PARALLEL and NOPARALLEL Loop Directives

General Compiler Directives: PARALLEL facilitates auto-parallelization for the immediately following DO loop. NOPARALLEL prevents this auto-parallelization.

Syntax

!DEC$ PARALLEL [ALWAYS]
!DEC$ NOPARALLEL

Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
PARALLEL helps the compiler to resolve dependencies, facilitating auto-parallelization of the immediately following DO loop. It instructs the compiler to ignore dependencies that it assumes may exist and which would prevent correct parallelization in the loop. However, if dependencies are proven, they are not ignored.

In addition, PARALLEL ALWAYS overrides the compiler heuristics that estimate the likelihood that parallelization of a loop will increase performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance.

NOPARALLEL prevents auto-parallelization of the immediately following DO loop.

These directives take effect only if you specify the compiler option that enables auto-parallelization.

---

**CAUTION.** The directive PARALLEL ALWAYS should be used with care. Overriding the heuristics of the compiler should only be done if you are absolutely sure the parallelization will improve performance.

---

**Example**

```fortran
program main
  parameter (n=100)
  integer x(n),a(n)
  !DEC$ NOPARALLEL
  do i=1,n
    x(i) = i
  enddo
  !DEC$ PARALLEL
  do i=1,n
    a( x(i) ) = i
  enddo
end
```

• Rules for General Directives that Affect DO Loops

PARALLEL DO

OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single DO directive.

Syntax

\[
\text{c}\$\text{OMP PARALLEL DO [clause[, clause] ... ]}
\]

\[
\text{do-loop}
\]

\[
[\text{c}\$\text{OMP END PARALLEL DO}]
\]

c

Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

clause

Can be any of the clauses accepted by the DO or PARALLEL directives.

do-loop

Is a DO iteration (a DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

You cannot branch out of a DO loop associated with a DO directive.

If the END PARALLEL DO directive is not specified, the PARALLEL DO is assumed to end with the DO loop that immediately follows the PARALLEL DO directive. If used, the END PARALLEL DO directive must appear immediately after the end of the DO loop.

The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a DO directive.

Example

In the following example, the loop iteration variable is private by default and it is not necessary to explicitly declare it. The END PARALLEL DO directive is optional:

\[
\text{c}\$\text{OMP PARALLEL DO}
\]

\[
\text{DO I=1,N}
\]

\[
\text{B(I) = (A(I) + A(I-1)) / 2.0}
\]

\[
\text{END DO}
\]

\[
\text{c}\$\text{OMP END PARALLEL DO}
\]
The following example shows how to use the REDUCTION clause in a PARALLEL DO directive:

```fortran
C$OMP PARALLEL DO DEFAULT(PRIVATE) REDUCTION(+: A,B)
DO I=1,N
   CALL WORK(ALOCAL,BLOCAL)
   A = A + ALOCAL
   B = B + BLOCAL
END DO
C$OMP END PARALLEL DO
```

See Also
- O to P
- OpenMP Fortran Compiler Directives

PARALLEL SECTIONS

**OpenMP Fortran Compiler Directive:** Provides an abbreviated way to specify a parallel region containing a single SECTIONS directive. The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a SECTIONS directive.

Syntax

```fortran
C$OMP PARALLEL SECTIONS [clause[,] clause] ... 
[C$OMP SECTION]
  block
[C$OMP SECTION
  block]...
C$OMP END PARALLEL SECTIONS
```

- `c` Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).
- `clause` Can be any of the clauses accepted by the PARALLEL or SECTIONS directives.
block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The last section ends at the END PARALLEL SECTIONS directive.

Example

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```fortran
#pragma omp parallel sections
#pragma omp section
  call xaxis
#pragma omp section
  call yaxis
#pragma omp section
  call zaxis
#pragma omp end parallel sections
```

See Also

- O to P
- OpenMP Fortran Compiler Directives

PARALLEL WORKSHARE

*OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single WORKSHARE directive.

Syntax

```fortran
#pragma omp parallel workshare [clause[,,] clause] ...

block

#pragma omp end parallel workshare
```

- c
  - Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

- clause
  - Is any of the clauses accepted by the PARALLEL or WORKSHARE directives.
block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).

See Also
- O to P
- OpenMP Fortran Compiler Directives
- WORKSHARE
- PARALLEL

PARAMETER

Statement and Attribute: Defines a named constant.

Syntax

The PARAMETER attribute can be specified in a type declaration statement or a PARAMETER statement, and takes one of the following forms:

Type Declaration Statement:

type, [att-ls,] PARAMETER [, att-ls] :: c = expr[, c = expr] ...

Statement:

PARAMETER [( ]c = expr[, c = expr] ... [)]

type Is a data type specifier.
att-ls Is an optional list of attribute specifiers.
c Is the name of the constant.
expr Is an initialization expression. It can be of any data type.

Description

The type, type parameters, and shape of the named constant are determined in one of the following ways:

- By an explicit type declaration statement in the same scoping unit.
- By the implicit typing rules in effect for the scoping unit. If the named constant is implicitly typed, it can appear in a subsequent type declaration only if that declaration confirms the implicit typing.
For example, consider the following statement:

```plaintext
PARAMETER (MU=1.23)
```

According to implicit typing, MU is of integer type, so MU=1. For MU to equal 1.23, it should previously be declared REAL in a type declaration or be declared in an IMPLICIT statement.

A named constant must not appear in a format specification or as the character count for Hollerith constants. For compilation purposes, writing the name is the same as writing the value.

If the named constant is used as the length specifier in a CHARACTER declaration, it must be enclosed in parentheses.

The name of a constant cannot appear as part of another constant, although it can appear as either the real or imaginary part of a complex constant.

You can only use the named constant within the scoping unit containing the defining PARAMETER statement.

Any named constant that appears in the initialization expression must have been defined previously in the same type declaration statement (or in a previous type declaration statement or PARAMETER statement), or made accessible by use or host association.

The use of parentheses is optional and can be controlled by using compiler option [no]altparam.

**Example**

The following example shows a type declaration statement specifying the PARAMETER attribute:

```plaintext
REAL, PARAMETER :: C = 2.9979251, Y = (4.1 / 3.0)
```

The following is an example of the PARAMETER statement:

```plaintext
REAL(4) PI, PIOV2
REAL(8) DPI, DPIOV2
LOGICAL FLAG
CHARACTER*(*) LONGNAME
PARAMETER (PI=3.1415927, DPI=3.141592653589793238D0)
PARAMETER (PIOV2=PI/2, DPIOV2=DPI/2)
PARAMETER (FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS')
```
The following shows another example:

```fortran
! implicit integer type
PARAMETER (nblocks = 10)

! implicit real type
IMPLICIT REAL (L-M)

PARAMETER (loads = 10.0, mass = 32.2)

! typed by PARAMETER statement
! Requires compiler option
PARAMETER mass = 47.3, pi = 3.14159

PARAMETER bigone = 'This constant is larger than forty characters'
! PARAMETER in attribute syntax

REAL, PARAMETER :: mass=47.3, pi=3.14159, loads=10.0, mass=32.2
```

- IMPLICIT
- Alternative syntax for the PARAMETER statement
- altparam compiler option

**PASSDIRKEYSQQ (W*32, W*64)**

*QuickWin Function*: Determines the behavior of direction and page keys in a QuickWin application.

**Module**

```fortran
USE IFQWIN
```

**Syntax**

```fortran
result = PASSDIRKEYSQQ (val)
```

*val* (Input) INTEGER(4) or LOGICAL(4).
A value of .TRUE. causes direction and page keys to be input as normal characters (the PassDirKeys flag is turned on). A value of .FALSE. causes direction and page keys to be used for scrolling.

The following constants, defined in IFQWIN.F90, can be used as integer arguments:

- **PASS_DIR_FALSE** - Turns off any special handling of direction keys. They are not passed to the program by GETCHARQQ.
- **PASS_DIR_TRUE** - Turns on special handling of direction keys. That is, they are passed to the program by GETCHARQQ.
- **PASS_DIR_INSDEL** - INSERT and DELETE are also passed to the program by GETCHARQQ.
- **PASS_DIR_CNTRLC** - Only needed for a QuickWin application, but harmless if used with a Standard Graphics application that already passes CTRL+C.

This value allows CTRL+C to be passed to a QuickWin program by GETCHARQQ if the following is true: the program must have removed the File menu EXIT item by using DELETEMENUQQ.

This value also passes direction keys and INSERT and DELETE.

**Results**

The return value indicates the previous setting of the PassDirKeys flag.

The return data type is the same as the data type of val; that is, either INTEGER(4) or LOGICAL(4).

When the PassDirKeys flag is turned on, the mouse must be used for scrolling since the direction and page keys are treated as normal input characters.

The PASSDIRKEYSQQ function is meant to be used primarily with the GETCHARQQ and INCHARQQ functions. Do not use normal input statements (such as READ) with the PassDirKeys flag turned on, unless your program is prepared to interpret direction and page keys.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

use IFQWIN

logical*4 res
character*1 ch,chl

Print *,"Type X to exit, S to scroll, D to pass Direction keys"
123 continue
ch = getcharqq( )
! check for escapes
! 0x00 0x?? is a function key
! 0xE0 0x?? is a direction key
if (ichar(ch) .eq. 0) then
   chl = getcharqq()
   print *,"function key follows escape = ",ichar(ch), " ",ichar(ch1)," ",ch1
goto 123
else if (ichar(ch) .eq. 224) then
   chl = getcharqq()
   print *,"direction key follows escape = ",ichar(ch)," ",ichar(ch1)," ",ch1
goto 123
else
   print *,ichar(ch)," ",ch
   if(ch .eq. 'S') then
      res = passdirkeysqq(.false.)
      print *, "Entering Scroll mode ",res
   endif
   if(ch .eq. 'D') then
      res = passdirkeysqq(.true.)
      print *, "Entering Direction keys mode ",res
   endif
if(ch .ne. 'X') go to 123
endif
end
The following example uses an integer constant as an argument to PASSDIRKEYSQQ:

```
c=======================================================================
c
c dirkeys4.for

c=======================================================================
c
Compile/Load Input Line for Standard Graphics Full Screen Window

c ifort /libs:qwins dirkeys4.for

c Compile/Load Input Line for QuickWin Graphics

c ifort /libs:qwin dirkeys4.for

c Program to illustrate how to get almost every character
from the keyboard in QuickWin or Standard Graphics mode.
Comment out the deletemenu line for Standard Graphics mode.

If you are doing a standard graphics application,
control C will come in as a Z'03' without further
effort.

In a QuickWin application, The File menu Exit item must
be deleted, and PassDirKeysQQ called with PASS_DIR_CNTRLC
to get control C.

use IFQWIN
```
integer(4) status
character*1 key1,key2,ch1
write(*,*) 'Initializing'
c-----don't do this for a Standard Graphics application
c remove File menu Exit item.
status = deletemenuqq(1,3)  ! stop QuickWin from getting control C
c-----set up to pass all keys to window including control c.
status = passdirkeysqq(PASS_DIR_CNTRLC)
c===============================================================================
c read and print characters
c==
c===============================================================================
10 key1 = getcharqq()
c-----first check for control+c
if(ichar(key1) .eq. 3) then
    write(*,*) 'Control C Received'
    write(*,*) "Really want to quit?"
    write(*,*) "Type Y <cr> to exit, or any other char <cr> to continue."
    read(*,*) ch1
    if(ch1.eq."y" .or. ch1.eq."Y") goto 30
    goto 10
endif
if(ichar(key1).eq.0) then ! function key?
    key2 = getcharqq()
    write(*,15) ichar(key1),ichar(key2),key2
    15 format(1x,2i12,1x,a1,' function key')
else
if(ichar(key1).eq.224) then ! direction key?
key2 = getcharqq()
write(*,16) ichar(key1),ichar(key2),key2
16 format(1x,2i12,1x,a1,' direction key')
else
write(*,20) key1,ichar(key1) ! normal key
20 format(1x,a1,i11)
endif
dendif
go to 10
30 stop
end

PAUSE

Statement: Temporarily suspends program execution and lets you execute operating system commands during the suspension. The PAUSE statement is a deleted feature in Fortran 95; it was obsolescent in Fortran 90. Intel Fortran fully supports features deleted in Fortran 95.

Syntax

PAUSE [pause-code]

pause-code (Optional) Is an optional message. It can be either of the following:
• A scalar character constant of type default character.
• A string of up to six digits; leading zeros are ignored. (Fortran 90 and FORTRAN 77 limit digits to five.)
If you specify \textit{pause-code}, the \texttt{PAUSE} statement displays the specified message and then displays the default prompt.

If you do not specify \textit{pause-code}, the system displays the following default message:

\begin{verbatim}
FORTRAN PAUSE
\end{verbatim}

The following prompt is then displayed:

- On Windows\textsuperscript{*} systems:
  \begin{verbatim}
  Fortran Pause - Enter command<CR> or <CR> to continue.
  \end{verbatim}

- On Linux\textsuperscript{*} and Mac OS\textsuperscript{*} X systems:
  \begin{verbatim}
  PAUSE prompt>
  \end{verbatim}

\textbf{Effect on Windows\textsuperscript{*} Systems}

The program waits for input on \texttt{stdin}. If you enter a blank line, execution resumes at the next executable statement.

Anything else is treated as a DOS command and is executed by a \texttt{system}() call. The program loops, letting you execute multiple DOS commands, until a blank line is entered. Execution then resumes at the next executable statement.

\textbf{Effect on Linux\textsuperscript{*} and Mac OS\textsuperscript{*} Systems}

The effect of \texttt{PAUSE} differs depending on whether the program is a foreground or background process, as follows:

- If a program is a foreground process, the program is suspended until you enter the \texttt{CONTINUE} command. Execution then resumes at the next executable statement.
  Any other command terminates execution.

- If a program is a background process, the behavior depends on \texttt{stdin}, as follows:
  \begin{itemize}
    \item If \texttt{stdin} is redirected from a file, the system displays the following (after the pause code and prompt):
      \begin{verbatim}
      To continue from background, execute 'kill -15 n'
      \end{verbatim}
      In this message, \texttt{n} is the process id of the program.
    \item If \texttt{stdin} is not redirected from a file, the program becomes a suspended background job, and you must specify \texttt{fg} to bring the job into the foreground. You can then enter a command to resume or terminate processing.
  \end{itemize}
Example

The following examples show valid PAUSE statements:

```
PAUSE 701
PAUSE 'ERRONEOUS RESULT DETECTED'
```

The following shows another example:

```
CHARACTER*24 filename
PAUSE 'Enter DIR to see available files or press RETURN' & $ if you already know filename.'
READ(*,'(A)') filename
OPEN(1, FILE=filename)
```

PEEKCHARQQ

**Run-Time Function:** Checks the keystroke buffer for a recent console keystroke and returns .TRUE. if there is a character in the buffer or .FALSE. if there is not.

**Module**

```
USE IFCORE
```

**Syntax**

```
result = PEEKCHARQQ(
```

**Results**

The result type is LOGICAL(4). The result is .TRUE. if there is a character waiting in the keyboard buffer; otherwise, .FALSE..
To find out the value of the key in the buffer, call GETCHARQQ. If there is no character waiting
in the buffer when you call GETCHARQQ, GETCHARQQ waits until there is a character in the
buffer. If you call PEEKCHARQQ first, you prevent GETCHARQQ from halting your process while
it waits for a keystroke. If there is a keystroke, GETCHARQQ returns it and resets PEEKCHARQQ
to .FALSE..

**Compatibility**

CONSOLE DLL LIB

**Example**

```fortran
USE IFCORE
LOGICAL(4) pressed / .FALSE. /
DO WHILE (.NOT. pressed)
   WRITE(*,*) ' Press any key'
   pressed = PEEKCHARQQ ( )
END DO
END
```

**See Also**

- GETCHARQQ
- GETSTRQQ
- FGETC
- GETC

**PERROR**

_Run-Time Subroutine:_ Sends a message to the
standard error stream, preceded by a specified
string, for the last detected error.

**Module**

USE IFCORE

**Syntax**

```fortran
CALL PERROR (string)
```
string (Input) Character*(*) Message to precede the standard error message.

The string sent is the same as that given by GERROR.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFCORE

character*24 errtext

errtext = 'In my opinion, '

...!

! any error message generated by errtext is
! preceded by 'In my opinion, '

Call PERROR (errtext)

**PIE, PIE_W (W*32, W*64)**

*Graphics Functions:* Draw a pie-shaped wedge in the current graphics color.

**Module**

USE IFQWIN

**Syntax**

result = PIE (i, x1, y1, x2, y2, x3, y3, x4, y4)

result = PIE_W (i, wx1, wy1, wx2, wy2, wx3, y3,wx4, wy4)
(Input) INTEGER(2). Fill flag. One of the following symbolic constants (defined in IFQWIN.F90):

- $GFILLINTERIOR - Fills the figure using the current color and fill mask.
- $GBORDER - Does not fill the figure.

(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

$x1, y1$

(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

$x2, y2$

(Input) INTEGER(2). Viewport coordinates of start vector.

$x3, y3$

(Input) INTEGER(2). Viewport coordinates of end vector.

$x4, y4$

(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

$wx1, wy1$

(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

$wx2, wy2$

(Input) REAL(8). Window coordinates of start vector.

$wx3, wy3$

(Input) REAL(8). Window coordinates of end vector.

$wx4, wy4$

Results

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the pie is clipped or partially out of bounds, the pie is considered successfully drawn and the return is 1. If the pie is drawn completely out of bounds, the return is 0.

The border of the pie wedge is drawn in the current color set by SETCOLORRGB.

The PIE function uses the viewport-coordinate system. The center of the arc is the center of the bounding rectangle, which is specified by the viewport-coordinate points $(x1, y1)$ and $(x2, y2)$. The arc starts where it intersects an imaginary line extending from the center of the arc through $(x3, y3)$, and it is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through $(x4, y4)$.

The PIE_W function uses the window-coordinate system. The center of the arc is the center of the bounding rectangle specified by the window-coordinate points $(wx1, wy1)$ and $(wx2, wy2)$. The arc starts where it intersects an imaginary line extending from the center of the arc through $(wx3, wy3)$. It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through $(wx4, wy4)$.
The fill flag option $GFILLINTERIOR is equivalent to a subsequent call to FLOODFILLRGB using the center of the pie as the starting point and the current graphics color (set by SETCOLORRGB) as the fill color. If you want a fill color different from the boundary color, you cannot use the $GFILLINTERIOR option. Instead, after you have drawn the pie wedge, change the current color with SETCOLORRGB and then call FLOODFILLRGB. You must supply FLOODFILLRGB with an interior point in the figure you want to fill. You can get this point for the last drawn pie or arc by calling GETARCINFO.

If you fill the pie with FLOODFILLRGB, the pie must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

NOTE. The PIE routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Pie routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Pie. For more information, see Building Applications: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines.

**POINTER - Fortran 95/90**

*Statement and Attribute:* Specifies that an object is a pointer (a dynamic variable). A pointer does not contain data, but points to a scalar or array variable where data is stored. A pointer has no initial storage set aside for it; memory storage is created for the pointer as a program runs.

**Syntax**

The POINTER attribute can be specified in a type declaration statement or a POINTER statement, and takes one of the following forms:
Type Declaration Statement:

\[
\text{type}, [\text{att-\text{ls}}] \quad \text{POINTER} \ [, \text{att-\text{ls}}] :: \text{ptr}[(d\text{-spec})][, \text{ptr}[(d\text{-spec})]]...
\]

Statement:

\[
\text{POINTER} \ [::]\text{ptr}[(d\text{-spec})][, \text{ptr}[(d\text{-spec})]] ...
\]

- \text{type-spec} Is a data type specifier.
- \text{att-\text{ls}} Is an optional list of attribute specifiers.
- \text{ptr} Is the name of the pointer. The pointer cannot be declared with the \text{INTENT} or \text{PARAMETER} attributes.
- \text{d-spec} (Optional) Is a deferred-shape specification (: [:] ...). Each colon represents a dimension of the array.

Description

No storage space is created for a pointer until it is allocated with an \text{ALLOCATE} statement or until it is assigned to a allocated target. A pointer must not be referenced or defined until memory is associated with it.

Each pointer has an association status, which tells whether the pointer is currently associated with a target object. When a pointer is initially declared, its status is undefined. You can use the \text{ASSOCIATED} intrinsic function to find the association status of a pointer if the pointer's association status is defined.

If the pointer is an array, and it is given the \text{DIMENSION} attribute elsewhere in the program, it must be declared as a deferred-shape array.

A pointer cannot be specified in an \text{EQUIVALENCE} or \text{NAMELIST} statement. A pointer in a \text{DATA} statement can only be associated with \text{NULL}().

Fortran 95/90 pointers are not the same as integer pointers. For more information, see the \text{POINTER - Integer} statement.

Example

The following example shows type declaration statements specifying the \text{POINTER} attribute:

```
TYPE(SYSTEM), POINTER :: CURRENT, LAST
REAL, DIMENSION(:,:), POINTER :: I, J, REVERSE
```

The following is an example of the \text{POINTER} statement:

```
TYPE(SYSTEM) :: TODAYS
POINTER :: TODAYS, A(:,:)
```
See also the examples `POINTER.F90` and `POINTER2.F90` in the TUTORIAL sample programs.

The following shows another example:

```fortran
REAL, POINTER :: arrow (:)
REAL, ALLOCATABLE, TARGET :: bullseye (:,:) ! The following statement associates the pointer with an unused block of memory.
ALLOCATE (arrow (1:8), STAT = ierr)
IF (ierr.eq.0) WRITE (*,'(/1x,a)') 'ARROW allocated'
arrow = 5.
WRITE (*,'(1x,8f8.0/)') arrow
ALLOCATE (bullseye (1:8,3), STAT = ierr)
IF (ierr.eq.0) WRITE (*,*) 'BULLSEYE allocated'
bullseye = 1.
bullseye (1:8:2,2) = 10.
WRITE (*,'(1x,8f8.0)') bullseye
! The following association breaks the association with the first target, which being unnamed and unassociated with other pointers, becomes lost. ARROW acquires a new shape.
arrow => bullseye (2:7,2)
WRITE (*,'(/1x,a)') 'ARROW is repointed & resized, all the 5s are lost'
WRITE (*,'(1x,8f8.0)') arrow
NULLIFY (arrow)
IF (.NOT. ASSOCIATED(arrow)) WRITE (*,'(/a/)') ' ARROW is not pointed'
DEALLOCATE (bullseye, STAT = ierr)
IF (ierr.eq.0) WRITE (*,*) 'Deallocation successful.'
END
```

**See Also**
- O to P
POINTER - Integer

**Statement:** Establishes pairs of objects and pointers, in which each pointer contains the address of its paired object. This statement is different from the Fortran 95/90 POINTER statement.

**Syntax**

```
POINTER (pointer, pointee) [, (pointer, pointee)] . . .
```

- **pointer**
  - Is a variable whose value is used as the address of the **pointee**.

- **pointee**
  - Is a variable; it can be an array name or array specification. It can also be a procedure named in an EXTERNAL statement or in a specific (non-generic) procedure interface block.

The following are **pointer** rules and behavior:

- Two pointers can have the same value, so pointer aliasing is allowed.
- When used directly, a pointer is treated like an integer variable. On IA-32 architecture, a pointer occupies one numeric storage unit, so it is a 32-bit quantity (INTEGER(4)). On Intel® 64 architecture and IA-64 architecture, a pointer occupies two numeric storage units, so it is a 64-bit quantity (INTEGER(8)).
- A pointer cannot be a pointee.
- A pointer cannot appear in an ASSIGN statement and cannot have the following attributes:
A pointer can appear in a DATA statement with integer literals only.

- Integers can be converted to pointers, so you can point to absolute memory locations.
- A pointer variable cannot be declared to have any other data type.
- A pointer cannot be a function return value.
- You can give values to pointers by doing the following:
  - Retrieve addresses by using the LOC intrinsic function (or the %LOC built-in function)
  - Allocate storage for an object by using the MALLOC intrinsic function (or by using malloc(3f) on Linux* and Mac OS* X systems)

For example:

Using %LOC:

```
INTEGER I(10)
INTEGER I1(10) /10*10/
POINTER (P,I)
```

Using MALLOC:

```
INTEGER I(10)
POINTER (P,I)
P = MALLOC(40)
I(2) = I(2) + 1
```

- The value in a pointer is used as the pointee's base address.

The following are pointee rules and behavior:

- A pointee is not allocated any storage. References to a pointee look to the current contents of its associated pointer to find the pointee's base address.
- A pointee cannot be data-initialized or have a record structure that contains data-initialized fields.
- A pointee can appear in only one integer POINTER statement.
- A pointee array can have fixed, adjustable, or assumed dimensions.
- A pointee cannot appear in a COMMON, DATA, EQUIVALENCE, or NAMELIST statement, and it cannot have the following attributes:
A pointee cannot be:
- A dummy argument
- A function return value
- A record field or an array element
- Zero-sized
- An automatic object
- The name of a generic interface block

If a pointee is of derived type, it must be of sequence type.

**Example**

```fortran
POINTER (p, k)
INTEGER j(2)
! This has the same effect as j(1) = 0, j(2) = 5
p = LOC(j)
k = 0
p = p + SIZEOF(k) ! 4 for 4-byte integer
k = 5
```

**POLYBEZIER, POLYBEZIER_W (W*32, W*64)**

**Graphics Functions:** Draw one or more Bezier curves.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = POLYBEZIER (ppoints, cpoints)
result = POLYBEZIER_W (wppoints, cpoints)
```

*ppoints* (Input) Derived type *xycoord*. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type *xycoord* is defined in IFQWIN.F90 as follows:

```fortran
MODULE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END MODULE xycoord
```

*cpoints* (Input) INTEGER(2). Number of points in *ppoints* or *wppoints*.

*wppoints* (Input) Derived type *wxycoord*. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type *wxycoord* is defined in IFQWIN.F90 as follows:

```fortran
MODULE wxycoord
  REAL(8) wx
  REAL(8) wy
END MODULE wxycoord
```

**Results**

The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.
A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point, the next two points are control points, and last point is the ending point. The starting point must be given for the first curve; subsequent curves use the ending point of the previous curve as their starting point. So, `cpoints` should contain 4 for one curve, 7 for 2 curves, 10 for 3 curves, and so forth.

POLYBEZIER does not use or change the current graphics position.

**POLYBEZIERTO, POLYBEZIERTO_W (W*32, W*64)**

*Graphics Functions:* Draw one or more Bezier curves.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = POLYBEZIERTO (ppoints, cpoints)
result = POLYBEZIERTO_W (wppoints, cpoints)
```

*ppoints*  
*(Input)* Derived type *xycoord*. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type *xycoord* is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

*cpoints*  
*(Input)* INTEGER(2). Number of points in *ppoints* or *wppoints*.

*wppoints*  
*(Input)* Derived type *wxycoord*. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type *wxycoord* is defined in IFQWIN.F90 as follows:

```fortran
TYPE wxycoord
  REAL(8) wx
  REAL(8) wy
END TYPE wxycoord
```

**Results**

The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.
A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point, the next two points are control points, and last point is the ending point. The starting point is the current graphics position as set by MOVETO for the first curve; subsequent curves use the ending point of the previous curve as their starting point. So, *cpoints* should contain 3 for one curve, 6 for 2 curves, 9 for 3 curves, and so forth.

POLYBEZIERTO moves the current graphics position to the ending point of the last curve drawn.

POLYGON, \texttt{POLYGON\_W (W*32, W*64)}

\textbf{Graphics Functions:} Draw a polygon using the current graphics color, logical write mode, and line style.

\textbf{Module}

\texttt{USE IFQWIN}

\textbf{Syntax}

\begin{verbatim}
result = POLYGON (control, ppoints, cpoints)
result = POLYGON\_W (control, wpoints, cpoints)
\end{verbatim}

\texttt{control}  
\begin{itemize}
  \item (Input) INTEGER(2). Fill flag. One of the following symbolic constants (defined in \texttt{IFQWIN.F90}):
  \begin{itemize}
    \item \texttt{GFILLINTERIOR} - Draws a solid polygon using the current color and fill mask.
    \item \texttt{GBORDER} - Draws the border of a polygon using the current color and line style.
  \end{itemize}
\end{itemize}

\texttt{ppoints}  
\begin{itemize}
  \item (Input) Derived type \texttt{xycoord}. Array of derived types defining the polygon vertices in viewport coordinates. The derived type \texttt{xycoord} is defined in \texttt{IFQWIN.F90} as follows:
  \begin{verbatim}
  TYPE xycoord
      INTEGER(2) xcoord
      INTEGER(2) ycoord
  END TYPE xycoord
  \end{verbatim}
\end{itemize}

\texttt{cpoints}  
\begin{itemize}
  \item (Input) INTEGER(2). Number of polygon vertices.
\end{itemize}
Derived type \texttt{wxycoord}. Array of derived types defining the polygon vertices in window coordinates. The derived type \texttt{wxycoord} is defined in \texttt{IFQWIN.F90} as follows:

\begin{verbatim}
TYPE wxycoord
  REAL(8) wx
  REAL(8) wy
END TYPE wxycoord
\end{verbatim}

**Results**

The result type is \texttt{INTEGER(2)}. The result is nonzero if anything is drawn; otherwise, 0.

The border of the polygon is drawn in the current graphics color, logical write mode, and line style, set with \texttt{SETCOLORRGB}, \texttt{SETWRITEMODE}, and \texttt{SETLINESTYLE}, respectively. The \texttt{POLYGON} routine uses the viewport-coordinate system (expressed in \texttt{xycoord} derived types), and the \texttt{POLYGON\_W} routine uses real-valued window coordinates (expressed in \texttt{wxycoord} types).

The arguments \texttt{ppoints} and \texttt{wppoints} are arrays whose elements are \texttt{xycoord} or \texttt{wxycoord} derived types. Each element specifies one of the polygon's vertices. The argument \texttt{cpoints} is the number of elements (the number of vertices) in the \texttt{ppoints} or \texttt{wppoints} array.

Note that \texttt{POLYGON} draws between the vertices in their order in the array. Therefore, when drawing outlines, skeletal figures, or any other figure that is not filled, you need to be careful about the order of the vertices. If you don't want lines between some vertices, you may need to repeat vertices to make the drawing backtrack and go to another vertex to avoid drawing across your figure. Also, \texttt{POLYGON} draws a line from the last specified vertex back to the first vertex.

If you fill the polygon using \texttt{FLOODFILLRGB}, the polygon must be bordered by a solid line style. Line style is solid by default and can be changed with \texttt{SETLINESTYLE}.

\begin{quote}
**NOTE.** The \texttt{POLYGON} routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Polygon routine by including the \texttt{IFWIN} module, you need to specify the routine name as \texttt{MSFWIN\$Polygon}. For more information, see \textit{Building Applications: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines}.
\end{quote}
Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as a Graphics App.

! Draw a skeletal box

USE IFQWIN

INTEGER(2) status

TYPE (xycoord) poly(12)

! Set up box vertices in order they will be drawn, &
! repeating some to avoid unwanted lines across box

poly(1)%xcoord = 50
poly(1)%ycoord = 80
poly(2)%xcoord = 85
poly(2)%ycoord = 35
poly(3)%xcoord = 185
poly(3)%ycoord = 35
poly(4)%xcoord = 150
poly(4)%ycoord = 80
poly(5)%xcoord = 50
poly(5)%ycoord = 80
poly(6)%xcoord = 50
poly(6)%ycoord = 180
poly(7)%xcoord = 150
poly(7)%ycoord = 180
poly(8)%xcoord = 185
poly(8)%ycoord = 135
poly(9)%xcoord = 185
poly(9)%ycoord = 35
poly(10)%xcoord = 150
poly(10)%ycoord = 80
poly(11)%xcoord = 150
poly(11)%ycoord = 180
poly(12)%xcoord = 150
poly(12)%ycoord = 80
status = SETCOLORRGB(Z'0000FF')
status = POLYGON($GBORDER, poly, INT2(12))

END

POLYLINEQQ (W*32, W*64)

Graphics Function: Draws a line between each successive x, y point in a given array.

Module
USE IFQWIN

Syntax
result = POLYLINEQQ (points, cnt)
points

(Input) An array of DF_POINT objects. The derived type DF_POINT is defined in IFQWIN.F90 as:

```fortran
type DF_POINT
  sequence
  integer(4) x
  integer(4) y
end type DF_POINT
```

cnt

(Input) INTEGER(4). Number of elements in the points array.

Results

The result type is INTEGER(4). The result is a nonzero value if successful; otherwise, zero.

POLYLINEQQ uses the viewport-coordinate system.

The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

The current graphics position is not used or changed as it is in the LINETO function.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS
Example

! Build for QuickWin or Standard Graphics
USE IFQWIN
TYPE(DF_POINT) points(12)
integer(4) result
integer(4) cnt, i
! load the points
do i = 1,12,2
   points(i).x =20*i
   points(i).y =10
   points(i+1).x =20*i
   points(i+1).y =60
end do
! A sawtooth pattern will appear in the upper left corner
result = POLYLINEQQ(points, 12)
end

POPCNT

*Elemental Intrinsic Function (Generic)*:
Returns the number of 1 bits in the integer argument.

Syntax

result = POPCNT (i)
i (Input) Must be of type integer or logical.

Results

The result type is the same as i. The result value is the number of 1 bits in the binary representation of the integer i.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

If the value of I is B'0...00011010110', the value of POPCNT(I) is 5.

POPPAR

**Elemental Intrinsic Function (Generic):**

*Returns the parity of the integer argument.*

Syntax

\[
\text{result} = \text{POPPAR}(i)
\]

i (Input) Must be of type integer or logical.

Results

The result type is the same as i. The result value is 1 if there are an odd number of 1 bits in the binary representation of the integer I. The result value is zero if there are an even number.

POPPAR(i) is the same as 1 .AND. POPCNT(i).

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example

If the value of I is B'0...00011010110', the value of POPPAR(I) is 1.
PRECISION

Inquiry Intrinsic Function (Generic): Returns the decimal precision in the model representing real numbers with the same kind parameter as the argument.

Syntax

result = PRECISION (x)

x  (Input) Must be of type real or complex; it can be scalar or array valued.

Results

The result is a scalar of type default integer. The result has the value INT((DIGITS( x) - 1) * LOG10(RADIX( x))). If RADIX( x) is an integral power of 10, 1 is added to the result.

Example

If X is a REAL(4) value, PRECISION(X) has the value 6. The value 6 is derived from INT ((24-1) * LOG10 (2.)) = INT (6.92...). For more information on the model for REAL(4), see Model for Real Data.

PREFETCH and NOPREFETCH

General Compiler Directives: PREFETCH enables a data prefetch from memory. Prefetching data can minimize the effects of memory latency. NOPREFETCH (the default) disables data prefetching. These directives affect the heuristics used in the compiler.

Syntax

cDEC$ PREFETCH [var1[: hint1[: distance1]] [,var2[: hint2[: distance2]]]...]  
cDEC$ NOPREFETCH [var1[,var2]...]  
  c  Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)  
  var  Is an optional memory reference.
**hint**

Is an optional integer initialization expression with the value 0, 1, 2, or 3. These are the same as the values for `hint` in the intrinsic subroutine `MM_PREFETCH`. To use this argument, you must also specify `var`.

**distance**

Is an optional integer initialization expression with a value greater than 0. It indicates the number of loop iterations to perform before the prefetch. To use this argument, you must also specify `var` and `hint`.

To use these directives, compiler option O2 or O3 must be set.

This directive affects the DO loop it precedes.

If you specify `PREFETCH` with no arguments, all arrays accessed in the DO loop will be prefetched.

If a loop includes expression `A(j)`, placing `cDEC$ PREFETCH A` in front of the loop instructs the compiler to insert prefetches for `A(j + d)` within the loop. The `d` is determined by the compiler.

**Example**

cDEC$ NOPREFETCH c

cDEC$ PREFETCH a

do i = 1, m
  b(i) = a{c(i)} + 1
enddo
The following example is valid on IA-64 architecture:

```fortran
sum = 0.d0
  do j=1,lastrow-firstrow+1
    i = rowstr(j)
    iresidue = mod( rowstr(j+1)-i, 8 )
    sum = 0.d0
    CDEC$ NOPREFETCH a,p,colidx
    do k=i,i+iresidue-1
      sum = sum + a(k)*p(colidx(k))
    enddo
    CDEC$ NOPREFETCH colidx
    CDEC$ PREFETCH a:1:40
    CDEC$ PREFETCH p:1:20
    do k=i+iresidue, rowstr(j+1)-8, 8
      sum = sum + a(k )*p(colidx(k )
      & + a(k+1)*p(colidx(k+1)) + a(k+2)*p(colidx(k+2))
      & + a(k+3)*p(colidx(k+3)) + a(k+4)*p(colidx(k+4))
      & + a(k+5)*p(colidx(k+5)) + a(k+6)*p(colidx(k+6))
      & + a(k+7)*p(colidx(k+7))
    enddo
    q(j) = sum
  enddo

Optimizing Applications: Prefetching Support
**PRESENT**

Inquiry Intrinsic Function (Generic): Returns whether or not an optional dummy argument is present, that is, whether it has an associated actual argument.

**Syntax**

\[
\text{result} = \text{PRESENT} (a)
\]

- **a** (Input) Must be an argument of the current procedure and must have the OPTIONAL attribute. An explicit interface for the current procedure must be visible to its caller; for more information, see Procedure Interfaces.

**Results**

The result is a scalar of type default logical. The result is .TRUE. if \(a\) is present; otherwise, the result is .FALSE..
Example
Consider the following:

```
MODULE MYMOD
  CONTAINS
  SUBROUTINE CHECK (X, Y)
    REAL X, Z
    REAL, OPTIONAL :: Y
    ... 
    IF (PRESENT (Y)) THEN
      Z = Y
    ELSE
      Z = X * 2
    END IF
  END SUBROUTINE CHECK
END MODULE MYMOD
...
USE MYMOD
CALL CHECK (15.0, 12.0) ! Causes Z to be set to 12.0
CALL CHECK (15.0) ! Causes Z to be set to 30.0
```
The following shows another example:

```fortran
CALL who( 1, 2 ) ! prints "A present" "B present"
CALL who( 1 ) ! prints "A present"
CALL who( b = 2 ) ! prints "B present"
CALL who( ) ! prints nothing

CONTAINS

SUBROUTINE who( a, b )
   INTEGER(4), OPTIONAL :: a, b
   IF (PRESENT(a)) PRINT *, 'A present'
   IF (PRESENT(b)) PRINT *, 'B present'
END SUBROUTINE who
```

END

See Also
- O to P

- Optional Arguments

PRINT

**Statement:** Displays output on the screen. **TYPE** is a synonym for PRINT. All forms and rules for the PRINT statement also apply to the TYPE statement.

**Syntax**

The PRINT statement is the same as a formatted, sequential WRITE statement, except that the PRINT statement must never transfer data to user-specified I/O units. You can override this restriction by using an environment variable. For more information, see *Building Applications: Logical Devices*.

A PRINT statement takes one of the following forms:

**Formatted:**

PRINT form[, io-list]

**Formatted - List-Directed:**

PRINT *[, io-list]
**Formatted - Namelist:**

PRINT nml

<table>
<thead>
<tr>
<th>form</th>
<th>Is the nonkeyword form of a format specifier (no FMT=).</th>
</tr>
</thead>
<tbody>
<tr>
<td>io-list</td>
<td>Is an I/O list.</td>
</tr>
<tr>
<td>*</td>
<td>Is the format specifier indicating list-directed formatting.</td>
</tr>
<tr>
<td>nml</td>
<td>Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.</td>
</tr>
</tbody>
</table>

**Example**

In the following example, one record (containing four fields of data) is printed to the implicit output device:

```plaintext
CHARACTER*16 NAME, JOB
PRINT 400, NAME, JOB
400 FORMAT ('NAME=', A, 'JOB=', A)
```

The following shows another example:

```plaintext
! The following statements are equivalent:
PRINT ' (A11)', 'Abbottsford'
WRITE (*, '(A11)') 'Abbottsford'
TYPE '(A11)', 'Abbottsford'
```

- PRINT as a value in CLOSE
PRIVATE Statement

**Statement and Attribute:** Specifies that entities in a module can be accessed only within the module itself.

**Syntax**

The PRIVATE attribute can be specified in a type declaration statement or a PRIVATE statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type[,att-ls,] PRIVATE [, att-ls] :: entity[, entity]...
```

**Statement:**

```
PRIVATE [[::] entity[, entity] ...]
```

- *type*: Is a data type specifier.
- *att-ls*: Is an optional list of attribute specifiers.
- *entity*: Is one of the following:
  - A variable name
  - A procedure name
  - A derived type name
  - A named constant
  - A namelist group name

In statement form, an entity can also be a generic identifier (a generic name, defined operator, or defined assignment).

**Description**

The PRIVATE attribute can only appear in the scoping unit of a module.

Only one PRIVATE statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module.

If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility. Entities with PUBLIC accessibility can be accessed from outside the module by means of a USE statement.

If a derived type is declared PRIVATE in a module, its components are also PRIVATE. The derived type and its components are accessible to any subprograms within the defining module through host association, but they are not accessible from outside the module.
If the derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module though use association (or host association) can access the derived-type definition, but not its components.

If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module has a generic identifier, it must also be declared PRIVATE.

If a procedure has a generic identifier, the accessibility of the procedure’s specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

**Example**

The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

```fortran
REAL, PRIVATE :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
```

The following is an example of the PUBLIC and PRIVATE statements:

```fortran
MODULE SOME_DATA
REAL ALL_B
PUBLIC ALL_B
TYPE RESTRICTED_DATA
REAL LOCAL_C
DIMENSION LOCAL_C(50)
END TYPE RESTRICTED_DATA
PRIVATE RESTRICTED_DATA
END MODULE
```

The following derived-type declaration statement indicates that the type is restricted to the module:

```fortran
TYPE, PRIVATE :: DATA
...
END TYPE DATA
```
The following example shows a PUBLIC type with PRIVATE components:

```fortran
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
    INTEGER C, D
  END TYPE
  ...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.
The following shows another example:

!LENGTH in module VECTRLEN calculates the length of a 2-D vector.

!The module contains both private and public procedures

```fortran
MODULE VECTRLEN
    PRIVATE SQUARE
    PUBLIC LENGTH
    CONTAINS
    SUBROUTINE LENGTH(x,y,z)
        REAL, INTENT(IN) x, y
        REAL, INTENT(OUT) z
        CALL SQUARE(x, y)
        z = SQRT(x + y)
        RETURN
    END SUBROUTINE
    SUBROUTINE SQUARE(x1,y1)
        REAL x1,y1
        x1 = x1**2
        y1 = y1**2
        RETURN
    END SUBROUTINE
END MODULE
```

PRIVATE Clause

**Parallel Directive Clause:** Declares specified variables to be private to each thread in a team.

**Syntax**

PRIVATE (list)

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

The following occurs when variables are declared in a PRIVATE clause:

- A new object of the same type is declared once for each thread in the team. The new object is no longer storage associated with the original object.
- All references to the original object in the lexical extent of the directive construct are replaced with references to the private object.
- Variables defined as PRIVATE are undefined for each thread on entering the construct and the corresponding shared variable is undefined on exit from a parallel construct.
- Contents, allocation state, and association status of variables defined as PRIVATE are undefined when they are referenced outside the lexical extent (but inside the dynamic extent) of the construct, unless they are passed as actual arguments to called routines.

PRODUCT

Transformational Intrinsic Function (Generic):
Returns the product of all the elements in an entire array or in a specified dimension of an array.

Syntax

result = PRODUCT (array[, dim] [,mask])

array  (Input) Must be an array of type integer, real, or complex.
dim  (Input; optional) Must be a scalar integer with a value in the range 1 to n, where n is the rank of array.
mask  (Input; optional) Must be of type logical and conformable with array.

Results

The result is an array or a scalar of the same data type as array.
The result is a scalar if dim is omitted or array has rank one.

The following rules apply if dim is omitted:

- If PRODUCT(array) is specified, the result is the product of all elements of array. If array has size zero, the result is 1.
- If PRODUCT(array, MASK=mask) is specified, the result is the product of all elements of array corresponding to true elements of mask. If array has size zero, or every element of mask has the value .FALSE., the result is 1.

The following rules apply if dim is specified:

- If array has rank one, the value is the same as PRODUCT(array[,MASK=mask]).
- An array result has a rank that is one less than array, and shape (d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n), where (d_1, d_2, ..., d_n) is the shape of array.
- The value of element (s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n) of PRODUCT(array, dim[,mask]) is equal to PRODUCT(array(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n) [,MASK=mask(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n)]).
**Example**

PRODUCT ((/2, 3, 4/)) returns the value 24 (the product of 2 * 3 * 4). PRODUCT ((/2, 3, 4/), DIM=1) returns the same result.

PRODUCT (C, MASK=C .LT. 0.0) returns the product of the negative elements of C.

A is the array

```
[ 1 4 7 ]
[ 2 3 5 ].
```

PRODUCT (A, DIM=1) returns the value (2, 12, 35), which is the product of all elements in each column. 2 is the product of 1 * 2 in column 1. 12 is the product of 4 * 3 in column 2, and so forth.

PRODUCT (A, DIM=2) returns the value (28, 30), which is the product of all elements in each row. 28 is the product of 1 * 4 * 7 in row 1. 30 is the product of 2 * 3 * 5 in row 2.

If array has shape (2, 2, 2), mask is omitted, and dim is 1, the result is an array result with shape (2, 2) whose elements have the following values.

<table>
<thead>
<tr>
<th>Resultant array element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>result(1, 1)</td>
<td>array(1, 1, 1) * array(2, 1, 1)</td>
</tr>
<tr>
<td>result(2, 1)</td>
<td>array(1, 2, 1) * array(2, 2, 1)</td>
</tr>
<tr>
<td>result(1, 2)</td>
<td>array(1, 1, 2) * array(2, 1, 2)</td>
</tr>
<tr>
<td>result(2, 2)</td>
<td>array(1, 2, 2) * array(2, 2, 2)</td>
</tr>
</tbody>
</table>
The following shows another example:

```fortran
INTEGER array (2, 3)
INTEGER AR1(3), AR2(2)
array = RESHAPE((/1, 4, 2, 5, 3, 6/), (/2,3/))
! array is 1 2 3
! 4 5 6
AR1 = PRODUCT(array, DIM = 1) ! returns [ 4 10 18 ]
AR2 = PRODUCT(array, MASK = array .LT. 6, DIM = 2) ! returns [ 6 20 ]
END
```

See Also

- O to P
- SUM

**PROGRAM**

*Statement:* Identifies the program unit as a main program and gives it a name.

**Syntax**

```fortran
[PROGRAM name]
  [specification-part]
  [execution-part]
[CONTAINS
  internal-subprogram-part]
END[PROGRAM [name]]
```

*name* Is the name of the program.

*specification-part* Is one or more specification statements, except for the following:

- INTENT (or its equivalent attribute)
- OPTIONAL (or its equivalent attribute)
- PUBLIC and PRIVATE (or their equivalent attributes)
An automatic object must not appear in a specification statement. If a SAVE statement is specified, it has no effect.

**execution-part**

Is one or more executable constructs or statements, except for ENTRY or RETURN statements.

**internal-subprogram-part**

Is one or more internal subprograms (defining internal procedures). The internal-subprogram-part is preceded by a CONTAINS statement.

**Description**

The PROGRAM statement is optional. Within a program unit, a PROGRAM statement can be preceded only by comment lines or an OPTIONS statement.

The END statement is the only required part of a program. If a name follows the END statement, it must be the same as the name specified in the PROGRAM statement.

The program name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A main program must not reference itself (either directly or indirectly).

**Example**

The following is an example of a main program:

```fortran
PROGRAM TEST
     INTEGER C, D, E(20,20) ! Specification part
     CALL SUB_1 ! Executable part
...
END PROGRAM TEST
```

```fortran
CONTAINS

    SUBROUTINE SUB_1 ! Internal subprogram
...
END SUBROUTINE SUB_1
```

END PROGRAM TEST
The following shows another example:

```plaintext
PROGRAM MyProg
PRINT *, 'hello world'
END
```

**See Also**
- O to P

*Building Applications*: Building Applications from Microsoft* Visual Studio* .NET Overview

**PROTECTED**

**Statement and Attribute**: Specifies limitations on the use of module entities.

**Syntax**

The PROTECTED attribute can be specified in a type declaration statement or a PROTECTED statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls, ] PROTECTED [, att-ls] :: entity[, entity] ...
```

**Statement:**

```
PROTECTED [:]entity[, entity] ...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `entity` Is the name of an entity in a module.

The PROTECTED attribute can only appear in the specification part of a module.

The PROTECTED attribute can only be specified for a named variable that is not in a common block.

A non-pointer object that has the PROTECTED attribute and is accessed by use association can not appear in a variable definition or as the target in a pointer assignment statement.

A pointer object that has the PROTECTED attribute and is accessed by use association must not appear as any of the following:

- A pointer-object in a NULLIFY statement
- A pointer-object in a pointer assignment statement
• An object in an ALLOCATE or DEALLOCATE statement
• An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

The following restrictions apply outside of the module in which the entity has been given the PROTECTED attribute:
• A non-pointer entity may not be defined or redefined.
• A pointer entity may not have its association status changed through the pointer.

Example
The following example shows a type declaration statement specifying the PROTECTED attribute:

```
INTEGER, PROTECTED :: D, E
```

Consider the following example:

```
MODULE counter_mod
    INTEGER, PROTECTED :: current = 0
    CONTAINS
    INTEGER FUNCTION next()
    current = current + 1  ! current can be modified here
    next = current
    RETURN
    END FUNCTION next
END MODULE counter_mod

PROGRAM test_counter
    USE counter_mod
    PRINT *, next()  ! Prints 1
    current = 42  ! Error: variable is protected
END PROGRAM test_counter
```

• O to P
• Modules and Module Procedures
PSECT

General Compiler Directive: Modifies characteristics of a common block.

Syntax

cDEC$ PSECT /common-name/ a[,a] ...

c
Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

common-name
Is the name of the common block. The slashes (/ ) are required.

a
Is one of the following:

- ALIGN= val or ALIGN= keyword
  Specifies minimum alignment for the common block. ALIGN only has an effect when specified on Windows* and Linux* systems.
  The val is a constant ranging from 0 through 6 on Windows* systems and 0 through 4 on Linux* systems. The specified number is interpreted as a power of 2. The value of the expression is the alignment in bytes.
  The keyword is one of the following:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Equivalent to val</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>0</td>
</tr>
<tr>
<td>WORD</td>
<td>1</td>
</tr>
<tr>
<td>LONG</td>
<td>2</td>
</tr>
<tr>
<td>QUAD</td>
<td>3</td>
</tr>
<tr>
<td>OCTA</td>
<td>4</td>
</tr>
<tr>
<td>PAGE(^1)</td>
<td>i32: 12</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Equivalent to val</th>
</tr>
</thead>
<tbody>
<tr>
<td>i64: 13</td>
<td></td>
</tr>
</tbody>
</table>

\[1\] Range is 0 to 13 except on L*X32, where the range is 0 to 12.

- **[NO]WRT**
  
  Determines whether the contents of a common block can be modified during program execution.

If one program unit changes one or more characteristics of a common block, all other units that reference that common block must also change those characteristics in the same way.

The defaults are ALIGN=OCTA and WRT.

**PUBLIC**

**Statement and Attribute:** Specifies that entities in a module can be accessed from outside the module (by specifying a USE statement).

**Syntax**

The PUBLIC attribute can be specified in a type declaration statement or a PUBLIC statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
    type,[att-ls,] PUBLIC [, att-ls] :: entity [, entity]...
```

**Statement:**

```fortran
    PUBLIC [::] entity [, entity] ...```

- **type**
  Is a data type specifier.
- **att-ls**
  Is an optional list of attribute specifiers.
- **entity**
  Is one of the following:
  - A variable name
  - A procedure name
  - A derived type name
  - A named constant
• A namelist group name

In statement form, an entity can also be a generic identifier (a
generic name, defined operator, or defined assignment).

Description
The PUBLIC attribute can only appear in the scoping unit of a module.
Only one PUBLIC statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module.
If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility.
If a derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module though use association (or host association) can access the derived-type definition, but not its components.
If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module has a generic identifier, it must also be declared PRIVATE.
If a procedure has a generic identifier, the accessibility of the procedure’s specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

Example
The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

REAL, PRIVATE :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
The following is an example of the PUBLIC and PRIVATE statements:

```fortran
MODULE SOME_DATA
  REAL ALL_B
  PUBLIC ALL_B
  TYPE RESTRICTED_DATA
    REAL LOCAL_C
    DIMENSION LOCAL_C(50)
  END TYPE RESTRICTED_DATA
  PRIVATE RESTRICTED_DATA
END MODULE
```

The following example shows a PUBLIC type with PRIVATE components:

```fortran
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
    INTEGER C, D
  END TYPE
  ...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.
The following shows another example:

!LENGTH in module VECTRLEN calculates the length of a 2-D vector.

!The module contains both private and public procedures

```fortran
MODULE VECTRLEN
  PRIVATE SQUARE
  PUBLIC LENGTH
CONTAINS
  SUBROUTINE LENGTH(x,y,z)
    REAL, INTENT(IN) x,y
    REAL, INTENT(OUT) z
    CALL SQUARE(x,y)
    z = SQRT(x + y)
  RETURN
END SUBROUTINE
  SUBROUTINE SQUARE(x1,y1)
    REAL x1,y1
    x1 = x1**2
    y1 = y1**2
  RETURN
END SUBROUTINE
END MODULE
```

PURE

**Keyword:** Asserts that a user-defined procedure has no side effects.

**Description**
This kind of procedure is specified by using the prefix PURE (or ELEMENTAL) in a FUNCTION or SUBROUTINE statement. Pure procedures are a Fortran 95 feature.

A pure procedure has no side effects. It has no effect on the state of the program, except for the following:

- For functions: It returns a value.
- For subroutines: It modifies INTENT(OUT) and INTENT(INOUT) parameters.

The following intrinsic and library procedures are implicitly pure:

- All intrinsic functions
- The elemental intrinsic subroutine MVBITS
- The intrinsic subroutine MOVE_ALLOC

A statement function is pure only if all functions that it references are pure.

Except for procedure arguments and pointer arguments, the following intent must be specified for all dummy arguments in the specification part of the procedure:

- For functions: INTENT(IN)
- For subroutines: any INTENT (IN, OUT, or INOUT)

A local variable declared in a pure procedure (including variables declared in any internal procedure) must not:

- Specify the SAVE attribute
- Be initialized in a type declaration statement or a DATA statement

The following variables have restricted use in pure procedures (and any internal procedures):

- Global variables
- Dummy arguments with INTENT(IN) (or no declared intent)
- Objects that are storage associated with any part of a global variable

They must not be used in any context that does either of the following:

- Causes their value to change. For example, they must not be used as:
  - The left side of an assignment statement or pointer assignment statement
  - An actual argument associated with a dummy argument with INTENT(OUT), INTENT(INOUT), or the POINTER attribute
  - An index variable in a DO or FORALL statement, or an implied-DO clause
  - The variable in an ASSIGN statement
  - An input item in a READ statement
  - An internal file unit in a WRITE statement
  - An object in an ALLOCATE, DEALLOCATE, or NULLIFY statement
  - An IOSTAT or SIZE specifier in an I/O statement, or the STAT specifier in an ALLOCATE or DEALLOCATE statement

- Creates a pointer to that variable. For example, they must not be used as:
  - The target in a pointer assignment statement
  - The right side of an assignment to a derived-type variable (including a pointer to a derived type) if the derived type has a pointer component at any level

A pure procedure must not contain the following:

- Any external I/O statement (including a READ or WRITE statement whose I/O unit is an external file unit number or *)
- A PAUSE statement
- A STOP statement

A pure procedure can be used in contexts where other procedures are restricted; for example:

- It can be called directly in a FORALL statement or be used in the mask expression of a FORALL statement.
- It can be called from a pure procedure. Pure procedures can only call other pure procedures.
- It can be passed as an actual argument to a pure procedure.
If a procedure is used in any of these contexts, its interface must be explicit and it must be declared pure in that interface.

**Example**

Consider the following:

```fortran
PURE FUNCTION DOUBLE(X)
   REAL, INTENT(IN) :: X
   DOUBLE = 2 * X
END FUNCTION DOUBLE
```

The following shows another example:

```fortran
PURE INTEGER FUNCTION MANDELBROT(X)
   COMPLEX, INTENT(IN) :: X
   COMPLEX__:: XTMP
   INTEGER__:: K
   ! Assume SHARED_DEFS includes the declaration
   ! INTEGER ITOL
   USE SHARED_DEFS
   K = 0
   XTMP = -X
   DO WHILE (ABS(XTMP) < 2.0 .AND. K < ITOL)
      XTMP = XTMP**2 - X
      K = K + 1
   END DO
   ITER = K
END FUNCTION
```
The following shows the preceding function used in an interface block:

INTERFACE
   PURE INTEGER FUNCTION MANDELBROT(X)
       COMPLEX, INTENT(IN) :: X
   END FUNCTION MANDELBROT
END INTERFACE

The following shows a FORALL construct calling the MANDELBROT function to update all the elements of an array:

FORALL (I = 1:N, J = 1:M)
   A(I,J) = MANDELBROT(COMPLEX((I-1)*1.0/(N-1), (J-1)*1.0/(M-1))
END FORALL

PUTC

Portability Function: Writes a character to Fortran external unit number 6.

Module
USE IFPORT

Syntax
result = PUTC (char)

char (Input) Character. Character to be written to external unit 6.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.
**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
use IFPORT
integer(4) i4
character*1 char1
do i = 1,26
   char1 = char(123-i)
   i4 = putc(char1)
   if (i4.ne.0) iflag = 1
endo
```

*Building Applications: Portability Library Overview*

**PUTIMAGE, PUTIMAGE_W (W*32, W*64)**

*Graphics Subroutines: Transfer the image stored in memory to the screen.*

**Module**

USE IFQWIN

**Syntax**

```fortran
CALL PUTIMAGE (x,y,image,action)
CALL PUTIMAGE_W (wx,wy,image,action)
```

*x, y* *(Input) INTEGER(2). Viewport coordinates for upper-left corner of the image when placed on the screen.*
**wx, wy**  
(Input) REAL(8). Window coordinates for upper-left corner of the image when placed on the screen.

**image**  

**action**  
(Input) INTEGER(2). Interaction of the stored image with the existing screen image. One of the following symbolic constants (defined in IFQWIN.F90):

- **$GAND** - Forms a new screen display as the logical AND of the stored image and the existing screen display. Points that have the same color in both the existing screen image and the stored image remain the same color, while points that have different colors are joined by a logical AND.
- **$GOR** - Superimposes the stored image onto the existing screen display. The resulting image is the logical OR of the image.
- **$GPRESET** - Transfers the data point-by-point onto the screen. Each point has the inverse of the color attribute it had when it was taken from the screen by GETIMAGE, producing a negative image.
- **$GPSET** - Transfers the data point-by-point onto the screen. Each point has the exact color attribute it had when it was taken from the screen by GETIMAGE.
- **$GXOR** - Causes points in the existing screen image to be inverted wherever a point exists in the stored image. This behavior is like that of a cursor. If you perform an exclusive OR of an image with the background twice, the background is restored unchanged. This allows you to move an object around without erasing the background. The $GXOR constant is a special mode often used for animation.

In addition, the following ternary raster operation constants can be used (described in the online documentation for the Windows* API BitBlt):

- **$GSRCCOPY** (same as $GPSET)
- **$GSRCPAINT** (same as $GOR)
- **$GSRCAND** (same as $GAND)
- **$GSRCINVERT** (same as $GXOR)
PUTIMAGE places the upper-left corner of the image at the viewport coordinates \((x, y)\).
PUTIMAGE_W places the upper-left corner of the image at the window coordinates \((wx, wy)\).

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as a Graphics App.

USE IFQWIN

INTEGER(1), ALLOCATABLE :: buffer(:)

INTEGER(2) status, x

INTEGER(4) imsize

status = SETCOLOR(INT2(4))

! draw a circle

status = ELLIPSE($GFILLINTERIOR, INT2(40), INT2(55), INT2(70), INT2(85))

imsize = IMAGESIZE(INT2(39), INT2(54), INT2(71), INT2(86))

ALLOCATE (buffer(imsize))

CALL GETIMAGE(INT2(39), INT2(54), INT2(71), INT2(86), buffer)

! copy a row of circles beneath it

DO x = 5, 395, 35
    CALL PUTIMAGE(x, INT2(90), buffer, $GPSET)
END DO

DEALLOCATE(buffer)

END

PXF(type)GET

POSIX Subroutine: Gets the value stored in a component (or field) of a structure.

Module
USE IFPOSIX

Syntax
CALL PXF(type)GET (jhandle, compname, value, ierror)

CALL PXF(type)GET (jhandle, compname, value, ilen, ierror) ! syntax when (type) is STR

(type)
A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFINTEGT</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFLGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFSTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFCHARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFDGLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFINTE8GET</td>
</tr>
</tbody>
</table>

jhandle (Input) INTEGER(4). A handle of a structure.
compname (Input) Character. The name of the component (or field) of the structure to retrieve data from.

value (Output) A variable, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type is INTEGER(4). Stores the value of the component (or field).
**ilen**
(Output) INTEGER(4). This argument can only be used when *(type)* is STR (PXFSTRGET). Stores the length of the returned string.

**ierror**
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXF*(type)*GET subroutines retrieve the value from component (or field) *compname* of the structure associated with handle *jhandle* into variable *value*.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**
See the example in PXFTIMES (which shows PXFINTGET and PXFINT8GET)

**See Also**
- O to P
- PXF*(type)*SET

**PXF*(type)*SET**

*POSIX Subroutine:* Sets the value of a component (or field) of a structure.

**Module**
USE IFPOSIX

**Syntax**

CALL PXF*(type)*SET *(jhandle, compname, value, ierror)*

CALL PXF*(type)*SET *(jhandle, compname, value, ilen, ierror)* ! syntax when *(type)* is STR

*(type)*
A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFINTSET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFREALSET</td>
</tr>
</tbody>
</table>

3221
Routine Name | Data Type    | Value   |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFLGCLSET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER*(*)</td>
<td>PXFSTRSET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFCHARSET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFDBLSET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFIN8TSET</td>
</tr>
</tbody>
</table>

### Input

- **jhandle** (Input) INTEGER(4). A handle of a structure.
- **compname** (Input) Character. The name of the component (or field) of the structure to write data to.
- **value** (Input) A variable, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type is INTEGER(4). The value for the component (or field).
- **ilen** (Input) INTEGER(4). This argument can only be used when (type) is STR (PXFSTRSET). The length of the string in value.

### Output

- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

### Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

### Example

See the example in PXFSTRUCTCREATE (which shows PXFSTRSET)

### See Also

- O to P
- PXF(type)GET
**PXFA<TYPE>GET**

**POSIX Subroutine:** Gets the array values stored in a component (or field) of a structure.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFA(type)GET (jhandle, compname, value, ialen, ierror)

CALL PXFA(type)GET (jhandle, compname, value, ialen, ilen, ierror) ! syntax when (type) is STR

(type) A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFAINTGET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFAREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFALGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFASTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFACHARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFADBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFAINT8GET</td>
</tr>
</tbody>
</table>

**jhandle** (Input) INTEGER(4). A handle of a structure.

**compname** (Input) Character. The name of the component (or field) of the structure to retrieve data from.

**value** (Output) An array, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type of the array is INTEGER(4). Stores the value of the component (or field).

**ialen** (Input) INTEGER(4). The size of array value.
ilen  
(Output) INTEGER(4). This argument can only be used when (type) is STR (PXFASTRGET). An array that stores the lengths of elements of array value.

ierror  
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFA(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA(type)GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

<td>INTEGER(8)</td>
<td>PXFAINT8SET</td>
</tr>
</tbody>
</table>

- **jhandle** (Input) INTEGER(4). A handle of a structure.
- **compname** (Input) Character. The name of the component (or field) of the structure to write data to.
- **value** (Input) An array, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type of the array is INTEGER(4). The value for the component (or field).
- **ialen** (Input) INTEGER(4). The size of array value.
- **ilen** (Input) INTEGER(4). This argument can only be used when (type) is STR (PXFASTRSET). An array that specifies the lengths of elements of array value.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFA(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA(type)GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- O to P
- PXFA(type)GET
• PXF(type)SET

**PXFACCESS**

*POSIX Subroutine: Determines the accessibility of a file.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFACCESS (path, ilen, iamode, ierror)

- **path** (Input) Character. The name of the file.
- **ilen** (Input) INTEGER(4). The length of the path string.
- **iamode** (Input) INTEGER(4). One or more of the following:
  - 0: Checks for existence of the file.
  - 1: Checks for execute permission.
  - 2: Checks for write access.
  - 4: Checks for read access.
  - 6: Checks for read/write access.

- **ierror** (Output) INTEGER(4). The error status.

If access is permitted, the result value is zero; otherwise, an error code. Possible error codes are:

- -1: A bad parameter was passed.
- ENOENT: The named directory does not exist.
- EACCESS: Access requested was denied.

On Windows* systems, if the name given is a directory name, the function only checks for existence. All directories have read/write access on Windows* systems.
PXFA

POSIX Subroutine: Schedules an alarm.

Module
USE IFPOSIX

Syntax
CALL PXFA (isecond, isecleft, ierror)

isecond (Input) INTEGER(4). The number of seconds before the alarm signal should be delivered.

isecleft (Output) INTEGER(4). The number of seconds remaining until any previously scheduled alarm signal is due to be delivered. It is set to zero if there was no previously scheduled alarm signal.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFA subroutine arranges for a SIGALRM signal to be delivered to the process in seconds ist.secd.

On Linux* and Mac OS* X systems, SIGALRM is a reserved defined constant that is equal to 14. You can use any other routine to install the signal handler. You can get SIGALRM and other signal values by using PXFCONST or IPXFCONST.

On Windows* systems, the SIGALRM feature is not supported, but the POSIX library has an implementation you can use. You can provide a signal handler for SIGALRM by using PXFSIGACTION.

Compatibility

See Also
- O to P
- PXFCONST
- IPXFCONST
PXFSIGACTION

PXFCALLSUBHANDLE

**POSIX Subroutine:** Calls the associated subroutine.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCALLSUBHANDLE (jhandle2, ival, ierror)

- **jhandle2** (Input) INTEGER(4). A handle to the subroutine.
- **ival** (Input) INTEGER(4). The argument to the subroutine.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFCALLSUBHANDLE subroutine, when given a subroutine handle, calls the associated subroutine.

PXGETSUBHANDLE should be used to obtain a subroutine handle.

**NOTE.** The subroutine cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

- PXGETSUBHANDLE
PXFCFGETISPEED (L^X, M^X)

**POSIX Subroutine:** Returns the input baud rate from a `termios` structure.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCFGETISPEED (jtermios, iospeed, ierror)

- **jtermios** ((Input) INTEGER(4). A handle of structure `termios`.
- **iospeed** ((Output) INTEGER(4). The returned value of the input baud rate from the structure associated with handle `jtermios`.
- **ierror** (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

**NOTE.** To get a handle for an instance of the `termios` structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

**See Also**
- O to P
- PXFSTRUCTCREATE
- PXFCFSETISPEED

PXFCFGETOSPEED (L^X, M^X)

**POSIX Subroutine:** Returns the output baud rate from a `termios` structure.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCFGETOSPEED (jtermios, iospeed, ierror)

- **jtermios** (Input) INTEGER(4). A handle of structure `termios`.

3229
iospeed  (Output) INTEGER(4). The returned value of the output baud rate from the structure associated with handle jtermios.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

NOTE. To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

PXFCFCHDIR

POSIX Subroutine: Changes the current working directory.

Module
USE IFPOSIX
Syntax
CALL PXFCHDIR (path, ilen, ierror)

path    (Input) Character. The directory to be changed to.
ilen     (Input) INTEGER(4). The length of the path string.
ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• O to P
• PXFMKDIR

PXFCHMOD
POSIX Subroutine: Changes the ownership mode of the file.

Module
USE IFPOSIX

Syntax
CALL PXFCHMOD (path, ilen, imode, ierror)

path    (Input) Character. The path to the file.
ilen     (Input) INTEGER(4). The length of the path string.
imode    (Input) INTEGER(4). The ownership mode of the file. On Windows* systems, see your Microsoft* Visual C++ Installation in the \include directory under sys\stat.h for the values of imode. On Linux* and Mac OS* X systems, use octal file-access mode.
ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
NOTE. On Linux and Mac OS X systems, you must have sufficient ownership permissions, such as being the owner of the file or having read/write access of the file.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFCHOWN (L*X, M*X)

POSIX Subroutine: Changes the owner and group of a file.

Module

USE IFPOSIX

Syntax

CALL PXFCHOWN (path,ilen,iowner,igroup,ierror)

path (Input) Character. The path to the file.
ilen (Input) INTEGER(4). The length of the path string.
iowner (Input) INTEGER(4). The owner UID.
igroup (Input) INTEGER(4). The group GID.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFCLEARENV

POSIX Subroutine: Clears the process environment.

Module

USE IFPOSIX

Syntax

CALL PXFCLEARENV (ierror)

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
After a call to PXFCLEARENV, no environment variables are defined.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFCLOSE**

*POSIX Subroutine:* Closes the file associated with the descriptor.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCLOSE (fd, ierror)

- **fd** (Input) INTEGER(4). A file descriptor.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- O to P
- PXFOPEN

**PXFCLOSEDIR**

*POSIX Subroutine:* Closes the directory stream.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCLOSEDIR (idirid, ierror)

- **idirid** (Input) INTEGER(4). The directory ID obtained from PXFOPENDIR.
- **ierror** (Output) INTEGER(4). The error status.
If successful, `ierror` is set to zero; otherwise, an error code.

The PXFCLOSEDIR subroutine closes the directory associated with `idirid`.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- O to P
- PXFOPENDIR

**PXFCONST**

*POSIX Subroutine:* Returns the value associated with a constant.

**Module**

USE IFPOSIX

**Syntax**

```fortran
CALL PXFCONST (constname, ival, ierror)
```

- `constname` *(Input) Character.* The name of one of the following constants:
  - `STDIN_UNIT`
  - `STDOUT_UNIT`
  - `STDERR_UNIT`
  - `EINVAL`
  - `ENONAME`
  - `ENOHANDLE`
  - `EARRAYLEN`
  - `ENOENT`
  - `ENOTDIR`
  - `EACCES`

The constants beginning with E signify various error values for the system variable `errno`. 
ival (Output) INTEGER(4). The returned value of the constant.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, it is set to -1.

For more information on these constants, see your Microsoft* Visual C++ documentation (Windows* systems) or the errno.h file (Linux* and Mac OS* X systems).

Compatibility

PXFCREAT

POSIX Subroutine: Creates a new file or rewrites an existing file.

Module
USE IFPOSIX

Syntax
CALL PXFCREAT (path, ilen, imode, ifildes, ierror)

path (Input) Character. The pathname of the file.
ilen (Input) INTEGER(4). The length of path string.
imode (Input) INTEGER(4). The mode of the newly created file. On Windows* systems, see your Microsoft* Visual C++ documentation for permitted mode values. On Linux* and Mac OS* X systems, use octal file-access mode.

ifildes (Output) INTEGER(4). The returned file descriptor.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**PXFCTERMID (L^X, M^X)**

*POSIX Subroutine: Generates a terminal pathname.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCTERMID (s, ilen, ierror)

- s (Output) Character. The returned pathname of the terminal.
- ilen (Output) INTEGER(4). The length of the returned value in the s string.
- ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

This subroutine returns a string that refers to the current controlling terminal for the current process.

**PXFDUP, PXFDUP2**

*POSIX Subroutine: Duplicates an existing file descriptor.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFDUP (ifildes, fid, ierror)

CALL PXFDUP2 (ifildes, ifildes2, ierror)

- ifildes (Input) INTEGER(4). The file descriptor to duplicate.
- fid (Output) INTEGER(4). The returned new duplicated file descriptor.
- ifildes2 (Input) INTEGER(4). The number for the new file descriptor.
- ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
The PXFDUP subroutine creates a second file descriptor for an opened file. The PXFDUP2 subroutine copies the file descriptor associated with ifildes. Integer number ifildes2 becomes associated with this new file descriptor, but the value of ifildes2 is not changed.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFE(type)GET**

**POSIX Subroutine:** Gets the value stored in an array element component (or field) of a structure.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFE(type)GET (jhandle, compname, index, value, ierr)

CALL PXFE(type)GET (jhandle, compname, index, value, ilen, ierr) ! syntax when (type) is STR

A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFEINTGET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFREALGET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFELGCLGET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER(*)</td>
<td>PXFESTRGET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFECHEARGET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFEDBLGET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFEINT8GET</td>
</tr>
</tbody>
</table>

$jhandle$ (Input) INTEGER(4). A handle of a structure.
**compname**
(Input) Character. The name of the component (or field) of the structure to retrieve data from.

**index**
(Input) INTEGER(4). The index of the array element to get data for.

**value**
(Output) A variable, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type is INTEGER(4). Stores the value of the component (or field).

**ilen**
(Output) INTEGER(4). This argument can only be used when (type) is STR (PXFESTRGET). Stores the length of the returned string.

**ierror**
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFE(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)GET subroutines are used, the array element with index index is accessed (read from the component or field).

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**
- O to P
- PXFE(type)SET
- PXF(type)GET

**PXFE(type)SET**

*POSIX Subroutine: Sets the value of an array element component (or field) of a structure.*

**Module**
USE IFPOSIX

**Syntax**

```fortran
CALL PXFE(type)SET (jhandle, compname, index, value, ierror)
```
CALL PXFE(type)SET (jhandle, compname, index, value, ilen, ierror) ! syntax when (type) is STR

(type) A placeholder for one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Data Type</th>
<th>Routine Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>INTEGER(4)</td>
<td>PXFEINTSET</td>
</tr>
<tr>
<td>REAL</td>
<td>REAL(4)</td>
<td>PXFREALSET</td>
</tr>
<tr>
<td>LGCL</td>
<td>LOGICAL(4)</td>
<td>PXFELGCLSET</td>
</tr>
<tr>
<td>STR</td>
<td>CHARACTER*(*)</td>
<td>PXFESTRSET</td>
</tr>
<tr>
<td>CHAR</td>
<td>CHARACTER(1)</td>
<td>PXFECHARSET</td>
</tr>
<tr>
<td>DBL</td>
<td>REAL(8)</td>
<td>PXFEDBLSET</td>
</tr>
<tr>
<td>INT8</td>
<td>INTEGER(8)</td>
<td>PXFEINT8SET</td>
</tr>
</tbody>
</table>

jhandle (Input) INTEGER(4). A handle of a structure.

compname (Input) Character. The name of the component (or field) of the structure to write data to.

index (Input) INTEGER(4). The index of the array element to write data to.

value (Input) A variable, whose data type depends on the value of (type). See the table above for the data types for each value; for example, if the value for (type) is INT, the data type is INTEGER(4). The value for the component (or field).

ilen (Input) INTEGER(4). This argument can only be used when (type) is STR (PXFESTRSET). The length of the string value.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFE(type)SET subroutines are similar to the PXF(type)SET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)SET subroutines are used, the array element with index index is accessed (written to the component or field).

PXFEXECV

**POSIX Subroutine:** Executes a new process by passing command-line arguments.

Module

USE IFPOSIX

Syntax

CALL PXFEXECV (path, lenpath, argv, lenargv, iargc, ierror)

- **path**  
  (Input) Character. The path to the new executable process.

- **lenpath**  
  (Input) INTEGER(4). The length of path string.

- **argv**  
  (Input) An array of character strings. Contains the command-line arguments to be passed to the new process.

- **lenargv**  
  (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.

- **iargc**  
  (Input) INTEGER(4). The number of command-line arguments

- **ierror**  
  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFEXECV subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array. If execution is successful, no return is made to the calling process.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
PXFEXECVE

**POSIX Subroutine:** Executes a new process by passing command-line arguments.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFEXECVE (path, lenpath, argv, lenargv, iargc, env, lenenv, ienvc, ierror)

- **path** (Input) Character. The path to the new executable process.
- **lenpath** (Input) INTEGER(4). The length of path string.
- **argv** (Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
- **lenargv** (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in argv.
- **iargc** (Input) INTEGER(4). The number of command-line arguments.
- **env** (Input) An array of character strings. Contains the environment settings for the new process.
- **lenenv** (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in env.
- **ienvc** (Input) INTEGER(4). The number of environment settings in env.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFEXECVE subroutine executes a new executable process (file) by passing command-line arguments specified in the argv array and environment settings specified in the env array.
See Also

• PXFEXECV
• PXFEXECVP

PXFEXECVP

**POSIX Subroutine:** Executes a new process by passing command-line arguments.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFEXECVP (file, lenfile, argv, lenargv, iargc, ierror)

- `file` (Input) Character. The filename of the new executable process.
- `lenfile` (Input) INTEGER(4). The length of `file` string.
- `argv` (Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
- `lenargv` (Input) INTEGER(4). An array that contains the lengths for each corresponding character string in `argv`.
- `iargc` (Input) INTEGER(4). The number of command-line arguments.
- `ierror` (Input) Character. The filename of the new executable process.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFEXECVP subroutine executes a new executable process(`file`) by passing command-line arguments specified in the `argv` array. It uses the PATH environment variable to find the file to execute.

**Compatibility**

• O to P
• PXFEXECV
• PXFEXECVE
PXEXIT, PXFFASTEXIT

POSIX Subroutine: Exits from a process.

Module
USE IFPOSIX

Syntax
CALL PXEXIT (istatus)
CALL PXFFASTEXIT (istatus)

istatus (Input) INTEGER(4). The exit value.

The PXEXIT subroutine terminates the calling process. It calls, in last-in-first-out (LIFO) order, the functions registered by C runtime functions atexit and onexit, and flushes all file buffers before terminating the process. The istatus value is typically set to zero to indicate a normal exit and some other value to indicate an error.

The PXFFASTEXIT subroutine terminates the calling process without processing atexit or onexit, and without flushing stream buffers.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
program t1

use ifposix

integer(4) ipid, istat, ierror, ipid_ret, istat_ret

print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
  print *," I am a child process"
  print *," My child's pid is", IPID_RET
  call PXFGETPPID(IPID_RET,IERROR)
  print *," The pid of my parent is", IPID_RET
  print *," Now I have exited with code 0xABCD"
  call PXFEXIT(Z'ABCD')
else
  print *," I am a parent process"
  print *," My parent pid is ", IPID_RET
  print *," I am creating the process with pid ", IPID
  print *," Now I am waiting for the end of the child process"
  call PXFWAIT(ISTAT, IPID_RET, IERROR)
  print *," The child with pid ", IPID_RET," has exited"
  if( PXFWIFEXITED(ISTAT) ) then
    print *, " The child exited normally"
    istat_ret = IPXFWEXITSTATUS(ISTAT)
    print 10," The low byte of the child exit code is", istat_ret
  end if
end if
10 FORMAT (A,Z)
end program

PXFFCNTL (L*X, M*X)
POSIX Subroutine: Manipulates an open file descriptor.

Module
USE IFPOSIX
Syntax

CALL PXFFCNTL (ifildes, icmd, iargin, iargout, ierror)

ifildes (Input) INTEGER(4). A file descriptor.
icmd (Input) INTEGER(4). Defines an action for the file descriptor.
iargin (Input; output) INTEGER(4). Interpretation of this argument depends on the value of icmd.
iargout (Output) INTEGER(4). Interpretation of this argument depends on the value of icmd.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

PXFFCNTL is a multi-purpose subroutine that causes an action to be performed on a file descriptor. The action, defined in icmd, can be obtained by using the values of predefined macros in C header fcntl.h, or by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_DUPFD</td>
<td>Returns into iargout the lowest available unopened file descriptor greater than or equal to iargin. The new file descriptor refers to the same open file as ifildes and shares any locks. The system flag FD_CLOEXEC for the new file descriptor is cleared so the new descriptor will not be closed on a call to PXFEXEC subroutine.</td>
</tr>
<tr>
<td>F_GETFD</td>
<td>Returns into iargout the value of system flag FD_CLOEXEC associated with ifildes. In this case, iargin is ignored.</td>
</tr>
<tr>
<td>F_SETFD</td>
<td>Sets or clears the system flag FD_CLOEXEC for file descriptor ifildes. The PXFEXEC family of functions will close all file descriptors with the FD_CLOEXEC flag set. The value for FD_CLOEXEC is obtained from argument iargin.</td>
</tr>
</tbody>
</table>
**F_GETFL**

Returns the file status flags for file descriptor `ifildes`. Unlike `F_GETFD`, these flags are associated with the file and shared by all descriptors. A combination of the following flags, which are symbolic names for `PXFCONST` or `IPXFCONST`, can be returned:

- **O_APPEND** - Specifies the file is opened in append mode.
- **O_NONBLOCK** - Specifies when the file is opened, it does not block waiting for data to become available.
- **O_RDONLY** - Specifies the file is opened for reading only.
- **O_RDWR** - Specifies the file is opened for both reading and writing.
- **O_WRONLY** - Specifies the file is opened for writing only.

**F_SETFL**

Sets the file status flags from `iargin` for file descriptor `ifildes`. Only `O_APPEND` or `O_NONBLOCK` flags can be modified. In this case, `iargout` is ignored.

**F_GETLK**

Gets information about a lock. Argument `iargin` must be a handle of structure `flock`. This structure is taken as the description of a lock for the file. If there is a lock already in place that would prevent this lock from being locked, it is returned to the structure associated with handle `iargin`. If there are no locks in place that would prevent the lock from being locked, field `l_type` in the structure is set to the value of the constant with symbolic name `F_UNLCK`. 
### Action

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_SETLK</td>
<td>Sets or clears a lock. Argument <code>iargin</code> must be a handle of structure <code>flock</code>. The lock is set or cleared according to the value of structure field <code>l_type</code>. If the lock is busy, an error is returned.</td>
</tr>
<tr>
<td>F_SETLKW</td>
<td>Sets or clears a lock, but causes the process to wait if the lock is busy. Argument <code>iargin</code> must be a handle of structure <code>flock</code>. The lock is set or cleared according to the value of structure field <code>l_type</code>. If the lock is busy, PXFCNTL waits for an unlock.</td>
</tr>
</tbody>
</table>

**NOTE.** To get a handle for an instance of the `flock` structure, use `PXFSTRUCTCREATE` with the string 'flock' for the structure name.

### See Also

- O to P
- PXFSTRUCTCREATE
- IPXFCONST
- PXFCONST

### PXFFDOPEN

**POSIX Subroutine:** Opens an external unit.

### Module

USE IFPOSIX

### Syntax

```fortran
CALL PXFFDOPEN (ifildes, iunit, access, ierror)
```

- `ifildes` (Input) INTEGER(4). The file descriptor of the opened file.
- `iunit` (Input) INTEGER(4). The Fortran logical unit to connect to file descriptor `ifildes`. 
(Input) Character. A character string that specifies the attributes for the Fortran unit. The string must consist of one or more of the following keyword/value pairs. Keyword/value pairs should be separated by a comma, and blanks are ignored.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Possible Values</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NEWLINE'</td>
<td>'YES' or 'NO'</td>
<td>I/O type</td>
<td>'YES'</td>
</tr>
<tr>
<td>'BLANK'</td>
<td>'NULL' or 'ZERO'</td>
<td>Interpretation of blanks</td>
<td>'NULL'</td>
</tr>
<tr>
<td>'STATUS'</td>
<td>'OLD', 'SCRATCH', or 'UNKNOWN'</td>
<td>File status at open</td>
<td>'UNKNOWN'</td>
</tr>
<tr>
<td>'FORM'</td>
<td>'FORMATTED' or 'UNFORMATTED'</td>
<td>Format type</td>
<td>'FORMATTED'</td>
</tr>
</tbody>
</table>

Keywords should be separated from their values by the equals ('=') character; for example:

call PXFDOPEN (IFILDES, IUNIT, 'BLANK=NULL, STATUS=UNKNOWN', IERROR)

*ierror*  
(Output) INTEGER(4). The error status.

The PXFFDOPEN subroutine connects an external unit identified by *iunit* to a file descriptor *ifildes*. If unit is already connected to a file, the file should be closed before using PXFFDOPEN.

**NOTE.** On Windows* systems, the default value of the POSIX/IO flag is 0, which causes PXFFDOPEN to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also
• O to P
• PXFPOSIXIO

PXFFFLUSH

**POSIX Subroutine:** Flushes a file directly to disk.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFFFLUSH (lunit,ierror)

lunit (Input) INTEGER(4). A Fortran logical unit.
ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFFLUSH subroutine writes any buffered output to the file connected to unit *lunit*.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFFGETC

**POSIX Subroutine:** Reads a character from a file.

**Module**
USE IFPOSIX

**Syntax**
CALL PXFFGETC (lunit,char,ierror)

lunit (Input) INTEGER(4). A Fortran logical unit.
char (Input) Character. The character to be read.
ierror (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFGETC subroutine reads a character from a file connected to unit *lunit*. 
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• O to P
• PXFFPUTC

PXFFILENO

POSIX Subroutine: Returns the file descriptor associated with a specified unit.

Module
USE IFPOSIX

Syntax
CALL PXFFILENO (lunit, fd, ierror)

lunit (Input) INTEGER(4). A Fortran logical unit.
fd (Output) INTEGER(4). The returned file descriptor.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. Possible error codes are:
• EINVAL: lunit is not an open unit.
• EBADF: lunit is not connected with a file descriptor.

The PXFFILENO subroutine returns in fd the file descriptor associated with lunit.

NOTE. On Windows* systems, the default value of the POSIX/IO flag is 0, which prevents OPEN from connecting a unit to a file descriptor and causes PXFFILENO to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1. This setting allows a connection to a file descriptor.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also
• O to P
• PXFPOSIXIO

PXFFORK (L*X, M*X)

POSIX Subroutine: Creates a child process that differs from the parent process only in its PID.

Module
USE IFPOSIX

Syntax
CALL PXFFORK (ipid, ierror)

ipid  (Output) INTEGER(4). The returned PID of the new child process.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFFORK subroutine creates a child process that differs from the parent process only in its PID. If successful, the PID of the child process is returned in the parent’s thread of execution, and a zero is returned in the child’s thread of execution. Otherwise, a -1 is returned in the parent’s context and no child process is created.

Example
program t1

use ifposix

integer(4) ipid, istat, ierr, ipid_ret, istat_ret

print *," the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *," I am a child process"
   print *," My child's pid is", IPID_RET
   call PXFGETPPID(IPID_RET,IERROR)
   print *," The pid of my parent is",IPID_RET
   print *," Now I have exited with code 0xABCD"
   call PXFEXIT(Z'ABCD')
else
   print *," I am a parent process"
   print *," My parent pid is ", IPID_RET
   print *," I am creating the process with pid", IPID
   print *," Now I am waiting for the end of the child process"
   call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *," The child with pid ", IPID_RET," has exited"
   if( PXFWIFEXITED(ISTAT) ) then
      print *, " The child exited normally"
      istat_ret = IPXFWEXITSTATUS(ISTAT)
      print 10," The low byte of the child exit code is", istat_ret
   end if
end if
10 FORMAT (A,Z)
end program

See Also
- O to P
- IPXWEXITSTATUS
PXFFPATHCONF

POSIX Subroutine: Gets the value for a configuration option of an opened file.

Module

USE IFPOSIX

Syntax

CALL PXFFPATHCONF (ifildes, name, ival, ierror)

- ifildes (Input) INTEGER(4). The file descriptor of the opened file.
- name (Input) INTEGER(4). The configurable option.
- ival (Output) INTEGER(4). The value of the configurable option.
- ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFFPATHCONF subroutine gets a value for the configuration option named for the opened file with descriptor ifildes.

The configuration option, defined in name, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>Returns the maximum number of links to the file. If ifildes refers to a directory, then the value applies to the whole directory.</td>
</tr>
<tr>
<td>_PC_MAX_CANON¹</td>
<td>Returns the maximum length of a formatted input line; the file descriptor ifildes must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_MAX_INPUT¹</td>
<td>Returns the maximum length of an input line; the file descriptor ifildes must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>Returns the maximum length of a filename in ifildes that the process is allowed to create.</td>
</tr>
</tbody>
</table>
### Constant | Action
--- | ---
_PC_PATH_MAX | Returns the maximum length of a relative pathname when ifildes is the current working directory.
_PC_PIPE_BUF | Returns the size of the pipe buffer; the file descriptor ifildes must refer to a pipe or FIFO.
_PC_CHOWN_RESTRICTED¹ | Returns nonzero if PXFCHOWN may not be used on this file. If ifildes refers to a directory, then this applies to all files in that directory.
_PC_NO_TRUNC¹ | Returns nonzero if accessing filenames longer than _POSIX_NAME_MAX will generate an error.
_PC_VDISABLE¹ | Returns nonzero if special character processing can be disabled; the file descriptor ifildes must refer to a terminal.

¹L*X, M*X

On Linux* and Mac OS* X systems, the corresponding macros are defined in `<unistd.h>`. The values for name can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in `<unistd.h>`. The following table shows the corresponding macro names for the above constants:

### Constant | Corresponding Macro
--- | ---
_PC_LINK_MAX | _POSIX_LINK_MAX
_PC_MAX_CANON | _POSIX_MAX_CANON
_PC_MAX_INPUT | _POSIX_MAX_INPUT
_PC_NAME_MAX | _POSIX_NAME_MAX
_PC_PATH_MAX | _POSIX_PATH_MAX
<table>
<thead>
<tr>
<th>Constant</th>
<th>Corresponding Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_PIPE_BUF</td>
<td>_POSIX_PIPE_BUF</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED</td>
<td>_POSIX_CHOWN_RESTRICTED</td>
</tr>
<tr>
<td>_PC_NO_TRUNC</td>
<td>_POSIX_NO_TRUNC</td>
</tr>
<tr>
<td>_PC_VDISABLE</td>
<td>_POSIX_VDISABLE</td>
</tr>
</tbody>
</table>

PXFFPUTC

**POSIX Subroutine:** Writes a character to a file.

Module
USE IFPOSIX

Syntax
CALL PXFFPUTC (lunit, char, ierror)

- **lunit** (Input) INTEGER(4). A Fortran logical unit.
- **char** (Input) Character. The character to be written.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

The PXFFPUTC subroutine writes a character to the file connected to unit **lunit**.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also
• O to P
• PXFFGETC

PXFFSEEK

**POSIX Subroutine:** Modifies a file position.

Module
USE IFPOSIX

Syntax
CALL PXFFSEEK (lunit, ioffset, iwhence, ierror)

- **lunit** (Input) INTEGER(4). A Fortran logical unit.
- **ioffset** (Input) INTEGER(4). The number of bytes away from **iwhence** to place the pointer.
- **iwhence** (Input) INTEGER(4). The position within the file. The value must be one of the following constants (defined in stdio.h):
  - SEEK_SET = 0 Offset from the beginning of the file.
  - SEEK_CUR = 1 Offset from the current position of the file pointer.
  - SEEK_END = 2 Offset from the end of the file.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code. Possible error codes are:

- **EINVAL:** No file is connected to **lunit**, **iwhence** is not a proper value, or the resulting offset is invalid.
- **ESPIPE:** **lunit** is a pipe or FIFO.
- **EEND:** The end of the file has been reached.

The PXFFSEEK subroutine modifies the position of the file connected to unit **lunit**.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**PXFFSTAT**

**POSIX Subroutine:** Gets a file's status information.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFFSTAT (ifildes, jstat, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor for an opened file.
- **jstat** (Input) INTEGER(4). A handle of structure stat.
- **ierror** (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFFSTAT subroutine puts the status information for the file associated with `ifildes` into the structure associated with handle `jstat`.

**NOTE.** To get a handle for an instance of the `stat` structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- O to P
- PXFSTRUCTCREATE

**PXFFTELL**

**POSIX Subroutine:** Returns the relative position in bytes from the beginning of the file.
Syntax

CALL PXFFTELL (lunit, ioffset, ierror)

lunit       (Input) INTEGER(4). A Fortran logical unit.
ioffset     (Output) INTEGER(4). The returned relative position in bytes from
            the beginning of the file.
ierror      (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXGETARG

POSIX Subroutine: Gets the specified command-line argument.

Module

USE IFPOSIX

Syntax

CALL PXGETARG (argnum, str, istr, ierror)

argnum     (Input) INTEGER(4). The number of the command-line argument.
str        (Output) Character. The returned string value.
istr       (Output) INTEGER(4). The length of the returned string; it is zero if
            an error occurs.
ierror     (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXGETARG subroutine places the command-line argument with number argnum into
character string str. If argnum is equal to zero, the value of the argument returned is the
command name of the executable file.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
See Also
- O to P
- IPXFARGC

**PXFGATTY**

*POSIX Subroutine: Tests whether a file descriptor is connected to a terminal.*

**Module**

USE IFPOSIX

**Syntax**

```fortran
CALL PXFGATTY (ifildes, isatty, ierror)
```

- `ifildes` (Input) INTEGER(4). The file descriptor.
- `isatty` (Output) LOGICAL(4). The returned value.
- `ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

If file descriptor `ifildes` is open and connected to a terminal, `isatty` returns .TRUE.; otherwise, .FALSE..

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFGETC**

*POSIX Subroutine: Reads a character from standard input unit 5.*

**Module**

USE IFPOSIX

**Syntax**

```fortran
CALL PXFGETC (nextcar, ierror)
```

- `nextcar` (Output) Character. The returned character that was read.
- `ierror` (Output) INTEGER(4). The error status.
If successful, $ierror$ is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**
- O to P
- PXFPUTC

**PXGETCWD**

*POSIX Subroutine*: Returns the path of the current working directory.

**Module**

USE IFPOSIX

**Syntax**

CALL PXGETCWD (buf, ilen, ierror)

- *buf*: (Output) Character. The returned pathname of the current working directory.
- *ilen*: (Output) INTEGER(4). The length of the returned pathname.
- *ierror*: (Output) INTEGER(4). The error status.

If successful, $ierror$ is set to zero; otherwise, an error code. A possible error code is EINVAL if the size of *buf* is insufficient.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXGETEGID (L*X, M*X)**

*POSIX Subroutine*: Gets the effective group ID of the current process.

**Module**

USE IFPOSIX
Syntax

CALL PXFGETEGID (iegid, ierror)

- **iegid**: (Output) INTEGER(4). The returned effective group ID.
- **ierror**: (Output) INTEGER(4). The error status.

Description

If successful, *ierror* is set to zero; otherwise, an error code.

The effective ID corresponds to the set ID bit on the file being executed.

**PXGETENV**

**POSIX Subroutine:** Gets the setting of an environment variable.

Module

USE IFPOSIX

Syntax

CALL PXFGETENV (name, lenname, value, lenval, ierror)

- **name**: (Input) Character. The name of the environment variable.
- **lenname**: (Input) INTEGER(4). The length of *name*.
- **value**: (Output) Character. The returned value of the environment variable.
- **lenval**: (Output) INTEGER(4). The returned length of *value*. If an error occurs, it returns zero.
- **ierror**: (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also

- O to P
- PXFSETENV
PXFGETEUID (L*X, M*X)

**POSIX Subroutine:** Gets the effective user ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFGETEUID (ieuid, ierror)

- **Output:** INTEGER(4). The returned effective user ID.
- **Output:** INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The effective ID corresponds to the set ID bit on the file being executed.

PXFGETGID (L*X, M*X)

**POSIX Subroutine:** Gets the real group ID of the current process.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFGETGID (igid, ierror)

- **Output:** INTEGER(4). The returned real group ID.
- **Output:** INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

**Example**

See the example in PXFGETGROUPS

**See Also**

- O to P
• **PXFSETGID**

**PXFGETGRGID (L*X, M*X)**

*POSIX Subroutine: Gets group information for the specified GID.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFGETGRGID (jgid, jgroup, ierror)

- *jgid* (Input) INTEGER(4). The group ID to retrieve information about.
- *jgroup* (Input) INTEGER(4). A handle of structure group.
- *ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is not changed; otherwise, an error code.

The PXFGETGRGID subroutine stores the group information from /etc/group for the entry that matches the group GID *jgid* in the structure associated with handle *jgroup*.

**NOTE.** To get a handle for an instance of the group structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

**Example**

See the example in PXFGETGROUPS

**See Also**

- O to P
- PXFSTRUCTCREATE

**PXFGETGRNAM (L*X, M*X)**

*POSIX Subroutine: Gets group information for the named group.*

**Module**

USE IFPOSIX
Syntax

CALL PXFGETGRNAM (name, ilen, jgroup, ierror)

name (Input) Character. The name of the group to retrieve information about.
ilen (Input) INTEGER(4). The length of the name string.
jgroup (Input) INTEGER(4). A handle of structure group.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is not changed; otherwise, an error code.

The PXFGETGRNAM subroutine stores the group information from /etc/group for the entry that matches the group name name in the structure associated with handle jgroup.

**NOTE.** To get a handle for an instance of the group structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

See Also
- O to P
- PXFSTRUCTCREATE

**PXFGETGROUPS (L*X, M*X)**

**POSIX Subroutine:** Gets supplementary group IDs.

Module

USE IFPOSIX

**Syntax**

CALL PXFGETGROUPS (igidsetsize, igrouplist, ngroups, ierror)

igidsetsize (Input) INTEGER(4). The number of elements in the igrouplist array.
igrouplist (Output) INTEGER(4). The array that has the returned supplementary group IDs.
ngroups (Output) INTEGER(4). The total number of supplementary group IDs for the process.
**ierror**  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFGETGROUPS subroutine returns, up to size *igidsetsize*, the supplementary group IDs in array *igrouplist*. It is unspecified whether the effective group ID of the calling process is included in the returned list. If the size is zero, the list is not modified, but the total number of supplementary group IDs for the process is returned.

**Example**

```fortran
program test5
  use ifposix
  implicit none
  integer(4) number_of_groups, ierror, isize, i, igid
  integer(4), allocatable, dimension(:) :: igrouplist
  integer(JHANDLE_SIZE) jgroup

  ! Get total number of groups in system
  ! call PXFGETGROUPS with 0

  call PXFGETGROUPS(0, igrouplist, number_of_groups, ierror)
  if(ierrerror.NE.0) STOP 'Error: first call of PXFGETGROUPS fails'
  print *, 'The number of groups in system ', number_of_groups

  ! Get Group IDs
  isize = number_of_groups
  ALLOCATE( igrouplist(isize))
  call PXFGETGROUPS(isize, igrouplist, number_of_groups, ierror)
  if(ierrerror.NE.0) then

PXGETLOGIN

POSIX Subroutine: Gets the name of the user.

Module
USE IFPOSIX

Syntax
CALL PXGETLOGIN (s, ilen, ierror)

s  (Output) Character. The returned user name.
ilen  (Output) INTEGER(4). The length of the string stored in s.
ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
PXFGETPGRP (L*X, M*X)

POSIX Subroutine: Gets the process group ID of the calling process.

Module
USE IFPOSIX

Syntax
CALL PXFGETPGRP (ipgrp, ierror)

ipgrp (Output) INTEGER(4). The returned process group ID.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
Each process group is a member of a session and each process is a member of the session in which its process group is a member.

PXFGETPID

POSIX Subroutine: Gets the process ID of the calling process.

Module
USE IFPOSIX

Syntax
CALL PXFGETPID (ipid, ierror)

ipid (Output) INTEGER(4). The returned process ID.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
program t1
use ifposix

integer(4) ipid, istat, ierror, ipid_ret, istat_ret

print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)

if(IPID.EQ.0) then
  print *, "I am a child process"
  print *, "My child's pid is", IPID_RET
  call PXFGETPPID(IPID_RET,IERROR)
  print *, "The pid of my parent is",IPID_RET

   print *," The child with pid ", IPID_RET," has exited"
   if( PXFWIFEXITED(ISTAT) ) then
      print *, " The child exited normally"
      istat_ret = IPFWEXITSTATUS(ISTAT)
      print 10," The low byte of the child exit code is", istat_ret
   end if
end if

10 FORMAT (A,Z)

end program

PXGETPWNUM (L*X, M*X)

POSIX Subroutine: Gets password information for a specified name.

Module
USE IFPOSIX
**Syntax**

CALL PXFGETPWNAM (name, ilen, jpasswd, ierror)

- **name** (Input) Character. The login name of the user to retrieve information about. For example, a login name might be "jsmith", while the actual name is "John Smith".
- **ilen** (Input) INTEGER(4). The length of the name string.
- **jpasswd** (Input) INTEGER(4). A handle of structure compnam.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is not changed; otherwise, an error code.

The PXFGETPWNAM subroutine stores the user information from /etc/passwd for the entry that matches the user name **name** in the structure associated with handle **jpasswd**.

**NOTE.** To get a handle for an instance of the compnam structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

**See Also**
- O to P
- PXFSTRUCTCREATE

**PXFGETPWUID(L*X,M*X)**

**POSIX Subroutine:** Gets password information for a specified UID.

**Module**
USE IFPOSIX

**Syntax**

CALL PXFGETPWUID (iuid, jpasswd, ierror)

- **iuid** (Input) INTEGER(4). The user ID to retrieve information about.
- **jpasswd** (Output) INTEGER(4). A handle of structure compnam.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.
The PXFGETPWUID subroutine stores the user information from /etc/passwd for the entry that matches the user ID iuid in the structure associated with handle jpasswd.

NOTE. To get a handle for an instance of the compnam structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

See Also
• O to P
• PXFSTRUCTCREATE

PXFGETSUBHANDLE

POSIX Subroutine: Returns a handle for a subroutine.

Module
USE IFPOSIX

Syntax
CALL PXFGETSUBHANDLE (sub, jhandle1, ierror)

sub
(Input) The Fortran subroutine to get a handle for.

jhandle1
(Output) INTEGER(4). The returned handle for the subroutine.

ierror
(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

NOTE. The argument sub cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**PXFGETUID (L*X, M*X)**

*POSIX Subroutine: Gets the real user ID of the current process.*

**Module**
USE IFPOSIX

**Syntax**
CALL PXFGETUID (iuid, ierror)

- *iuid* (Output) INTEGER(4). The returned real user ID.
- *ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

**See Also**
- O to P
- PXFSETUID

**PXFISBLK**

*POSIX Function: Tests for a block special file.*

**Module**
USE IFPOSIX

**Syntax**
result = PXFISBLK (m)

- *m* (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.

**Results**
The result type is logical. If the file is a block special file, the result value is .TRUE.; otherwise, .FALSE..
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• O to P
• PXFISCHR

PXFISCHR

**POSIX Function:** Tests for a character file.

Module
USE IFPOSIX

Syntax
```
result = PXFISCHR (m)
m (Input) INTEGER(4). The value of the st_mode component (field) in the structure stat.
```

Results
The result type is logical. If the file is a character file, the result value is .TRUE.; otherwise, .FALSE..

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• O to P
• PXFISBLK

PXFISCONST

**POSIX Function:** Tests whether a string is a valid constant name.

Module
USE IFPOSIX
Syntax

\[
\text{result} = \text{PXFISCONST} \ (s)
\]

\(s\) (Input) Character. The name of the constant to test.

Results

The result type is logical. The PXFISCONST function confirms whether the argument is a valid constant name that can be passed to functions PXFCONST and IPXFCONST. It returns .TRUE. only if IPXFCONST will return a valid value for name \(s\).

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also

- O to P
- IPXFCONST
- PXFCONST

PXFISDIR

**POSIX Function:** Tests whether a file is a directory.

Module

USE IFPOSIX

Syntax

\[
\text{result} = \text{PXFISDIR} \ (m)
\]

\(m\) (Input) INTEGER(4). The value of the \(\text{st\_mode}\) component (field) in the structure \(\text{stat}\).

Results

The result type is logical. If the file is a directory, the result value is .TRUE.; otherwise, .FALSE..

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**PXFISFIFO**

*POSIX Function*: Tests whether a file is a special FIFO file.

**Module**

USE IFPOSIX

**Syntax**

\[
\text{result} = \text{PXFISFIFO}(m)
\]

*\(m\)* (Input) INTEGER(4). The value of the \text{st_mode}\text{component (field)} in the structure \text{stat}.

**Results**

The result type is logical.

The PXFISFIFO function tests whether the file is a special FIFO file created by PXFMKFIFO. If the file is a special FIFO file, the result value is \text{.TRUE.}; otherwise, \text{.FALSE.}.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- O to P
- PXFMKFIFO
- PXFISREG

**PXFISREG**

*POSIX Function*: Tests whether a file is a regular file.

**Module**

USE IFPOSIX

**Syntax**

\[
\text{result} = \text{PXFISREG}(m)
\]
The value of the `st_mode` component (field) in the structure `stat`.

**Results**
The result type is logical. If the file is a regular file, the result value is `.TRUE.`; otherwise, `.FALSE.`.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**
- O to P
- PXFMKFIFO
- PXFISFIFO

**PXFKILL**
*POSIX Subroutine: Sends a signal to a specified process.*

**Module**
USE IFPOSIX

**Syntax**
CALL PXFKILL (ipid, isig, ierror)

- `ipid` (Input) INTEGER(4). The process to kill. It is determined by one of the following values:
  - `> 0`  Kills the specific process.
  - `< 0`  Kills all processes in the group.
  - `== 0` Kills all processes in the group except special processes.
  - `== pid_t-1` Kills all processes.

- `isig` (Input) INTEGER(4). The value of the signal to be sent.
ierror               (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFKILL subroutine sends a signal with value isig to a specified process. On Windows* systems, only the ipid for the current process can be used.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFLINK**

**POSIX Subroutine:** Creates a link to a file or directory.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFLINK (existing, lenexist, new, lennew, ierror)

existing          (Input) Character. The path to the file or directory you want to link to.

lenexist          (Input) INTEGER(4). The length of the existing string.

new               (Input) Character. The name of the new link file.

lennew            (Input) INTEGER(4). The length of the new string.

ierror            (Output) INTEGER(4). The error status.

If successful, ierror is not changed; otherwise, an error code.

The PXFLINK subroutine creates a new link (also known as a hard link) to an existing file. This new name can be used exactly as the old one for any operation. Both names refer to the same file (so they have the same permissions and ownership) and it is impossible to tell which name was the "original".

**NOTE.** On Windows* systems, this subroutine is only valid for NTFS file systems; for FAT systems, it returns an error.
Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFLCALTIME

**POSIX Subroutine:** Converts a given elapsed time in seconds to local time.

Module
USE IFPOSIX

Syntax

```call pxflcaltime (isecnds, iatime, ierror)`
```

- `isecnds` (Input) INTEGER(4). The elapsed time in seconds since 00:00:00 Greenwich Mean Time, January 1, 1970.
- `iatime` (Output) INTEGER(4). One-dimensional array with 9 elements containing numeric time data. The elements of `iatime` are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iatime(1)</code></td>
<td>Seconds (0-59)</td>
</tr>
<tr>
<td><code>iatime(2)</code></td>
<td>Minutes (0-59)</td>
</tr>
<tr>
<td><code>iatime(3)</code></td>
<td>Hours (0-23)</td>
</tr>
<tr>
<td><code>iatime(4)</code></td>
<td>Day of month (1-31)</td>
</tr>
<tr>
<td><code>iatime(5)</code></td>
<td>Month (1-12)</td>
</tr>
<tr>
<td><code>iatime(6)</code></td>
<td>Gregorian year (for example, 1990)</td>
</tr>
<tr>
<td><code>iatime(7)</code></td>
<td>Day of week (0-6, where 0 is Sunday)</td>
</tr>
<tr>
<td><code>iatime(8)</code></td>
<td>Day of year (1-366)</td>
</tr>
<tr>
<td>Element</td>
<td>Value</td>
</tr>
<tr>
<td>------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>iatime(9)</td>
<td>Daylight savings flag (1 if daylight savings time is in effect; otherwise, 0)</td>
</tr>
</tbody>
</table>

**ierror**

(Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFLOCALTIME subroutine converts the time (in seconds since epoch) in the isecnds argument to the local date and time as described by the array iatime above.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFLSEEK**

**POSIX Subroutine:** Positions a file a specified distance in bytes.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFLSEEK (ifildes, ioffset, iwhence, iposition, ierror)

- ifildes (Input) INTEGER(4). A file descriptor.
- ioffset (Input) INTEGER(4). The number of bytes to move.
- iwhence (Input) INTEGER(4). The starting position. The value must be one of the following:
  - SEEK_SET = 0
    Sets the offset to ioffset bytes.
  - SEEK_CUR = 1
    Sets the offset to its current location plus ioffset bytes.
  - SEEK_END = 2
    Sets the offset to the size of the file plus ioffset bytes.
iposition (Output) INTEGER(4). The ending position; the resulting offset location as measured in bytes from the beginning of the file.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFLSEEK subroutine repositions the offset of file descriptor ifildes to the argument ioffset according to the value of argument iwhence.

PXFLSEEK allows the file offset to be set beyond the end of the existing end-of-file. If data is later written at this point, subsequent reads of the data in the gap return bytes of zeros (until data is actually written into the gap).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFMKDIR**

**POSIX Subroutine: Creates a new directory.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFMKDIR (path, ilen, imode, ierror)

path (Input) Character. The path for the new directory.
ilen (Input) INTEGER(4). The length of path string.
imode (L*X only) (Input) INTEGER(4). The mode mask. Octal file-access mode.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- O to P
- PXFRMDIR
- PXFCHDIR
PXFMKFIFO (L*X, M*X)

POSIX Subroutine: Creates a new FIFO.

Module
USE IFPOSIX

Syntax
CALL PXFMKFIFO (path, ilen, imode, ierror)

- **path** (Input) Character. The path for the new FIFO.
- **ilen** (Input) INTEGER(4). The length of **path** string.
- **imode** (Input) INTEGER(4). The mode mask; specifies the FIFO’s permissions. Octal file-access mode.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFMKFIFO subroutine creates a FIFO special file with name **path**. A FIFO special file is similar to a pipe, except that it is created in a different way. Once a FIFO special file is created, any process can open it for reading or writing in the same way as an ordinary file.

However, the FIFO file has to be open at both ends simultaneously before you can proceed to do any input or output operations on it. Opening a FIFO for reading normally blocks it until some other process opens the same FIFO for writing, and vice versa.

See Also
- O to P
- PXFISFIFO

PXFOPEN

POSIX Subroutine: Opens or creates a file.

Module
USE IFPOSIX

Syntax
CALL PXFOPEN (path, ilen, iopenflag, imode, ifildes, ierror)
path (Input) Character. The path of the file to be opened or created.
ilen (Input) INTEGER(4). The length of path string.
iopenflag (Input) INTEGER(4). The flags for the file. (For possible constant names that can be passed to PXFCONST or IPXFCONST, see below.)
imode (Input) INTEGER(4). The permissions for a new file. This argument should always be specified when iopenflag=O_CREAT; otherwise, it is ignored. (For possible permissions, see below.)
ifildes (Output) INTEGER(4). The returned file descriptor for the opened or created file.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

For iopenflag, you should specify one of the following constant values:

- O_RDONLY (read only)
- O_WRONLY (write only)
- O_RDWR (read and write)

In addition, you can also specify one of the following constant values by using a bitwise inclusive OR (IOR):

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>O_CREAT</td>
<td>Creates a file if the file does not exist.</td>
</tr>
<tr>
<td>O_EXCL</td>
<td>When used with O_CREAT, it causes the open to fail if the file already exists. In this case, a symbolic link exists, regardless of where it points to.</td>
</tr>
<tr>
<td>O_NOCTTY¹</td>
<td>If path refers to a terminal device, it prevents it from becoming the process's controlling terminal even if the process does not have one.</td>
</tr>
<tr>
<td>O_TRUNC</td>
<td>If the file already exists, it is a regular file, and imode allows writing (its value is O_RDWR or O_WRONLY), it causes the file to be truncated to length 0.</td>
</tr>
<tr>
<td>Value</td>
<td>Action</td>
</tr>
<tr>
<td>-----------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>O_APPEND</td>
<td>Opens the file in append mode. Before each write, the file pointer is positioned at the end of the file, as if with PXFLSEEK.</td>
</tr>
<tr>
<td>O_NONBLOCK (or O_NDELAY)¹</td>
<td>When possible, opens the file in non-blocking mode. Neither the open nor any subsequent operations on the file descriptor that is returned will cause the calling process to wait. This mode need not have any effect on files other than FIFOs.</td>
</tr>
<tr>
<td>O_SYNC</td>
<td>Opens the file for synchronous I/O. Any writes on the resulting file descriptor will block the calling process until the data has been physically written to the underlying hardware.</td>
</tr>
<tr>
<td>O_NOFOLLOW¹</td>
<td>If <code>path</code> is a symbolic link, it causes the open to fail.</td>
</tr>
<tr>
<td>O_DIRECTORY¹</td>
<td>If <code>path</code> is not a directory, it causes the open to fail.</td>
</tr>
<tr>
<td>O_LARGEFILE¹</td>
<td>On 32-bit systems that support the Large Files System, it allows files whose sizes cannot be represented in 31 bits to be opened.</td>
</tr>
<tr>
<td>O_BINARY²</td>
<td>Opens the file in binary (untranslated) mode.</td>
</tr>
<tr>
<td>O_SHORT_LIVED²</td>
<td>Creates the file as temporary. If possible, it does not flush to the disk.</td>
</tr>
<tr>
<td>O_TEMPORARY²</td>
<td>Creates the file as temporary. The file is deleted when last file handle is closed.</td>
</tr>
<tr>
<td>O_RANDOM²</td>
<td>Specifies primarily random access from the disk.</td>
</tr>
</tbody>
</table>
ActionValue

O_SEQUENTIAL\(^2\) Specifies primarily sequential access from the disk.

O_TEXT\(^2\) Opens the file in text (translated) mode.\(^3\)

\(^1\) L*X only
\(^2\) W*32, W*64
\(^3\) W*32, W*64

For more information, see "Text and Binary Modes" in the Visual C++\(^*\) programmer's guide.

Argument \(\text{imode}\) specifies the permissions to use if a new file is created. The permissions only apply to future accesses of the newly created file. The value for \(\text{imode}\) can be any of the following constant values (which can be obtained by using PXFCONST or IPXFCONST):

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>S_IRWXU</td>
<td>00700 user (file owner) has read, write and execute permission.</td>
</tr>
<tr>
<td>S_IRUSR, S_IWRITE</td>
<td>00400 user has read permission.</td>
</tr>
<tr>
<td>S_IWUSR, S_IEXEC</td>
<td>00200 user has write permission.</td>
</tr>
<tr>
<td>S_IXUSR, S_IEXEC</td>
<td>00100 user has execute permission.</td>
</tr>
<tr>
<td>S_IRWXG(^1)</td>
<td>00070 group has read, write and execute permission.</td>
</tr>
<tr>
<td>S_IRGRP(^1)</td>
<td>00040 group has read permission.</td>
</tr>
<tr>
<td>S_IWGRP(^1)</td>
<td>00020 group has write permission.</td>
</tr>
<tr>
<td>S_IXGRP(^1)</td>
<td>00010 group has execute permission.</td>
</tr>
<tr>
<td>S_IRWXO(^1)</td>
<td>00007 others have read, write and execute permission.</td>
</tr>
<tr>
<td>S_IROTH(^1)</td>
<td>00004 others have read permission.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>S_IWOTH¹</td>
<td>00002 others have write permission.</td>
</tr>
<tr>
<td>S_IXOTH¹</td>
<td>00001 others have execute permission.</td>
</tr>
</tbody>
</table>

¹L*X only

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

The following call opens a file for writing only and if the file does not exist, it is created:

```fortran
CALL PXFOPEN( "OPEN.OUT", &
              8, &
              IOR( IPXFCONST(O_WRONLY), IPXFCONST(O_CREAT) ), &
              IOR( IPXFCONST(S_IREAD), IPXFCONST(S_IWRITE) )
```

**See Also**

- O to P
- PXFCLOSE
- IPXFCONST
- PXFCONST

**PXFOPENDIR**

*POSIX Subroutine:* Opens a directory and associates a stream with it.

**Module**

USE IFPOSIX

**Syntax**

```fortran
CALL PXFOPENDIR (dirname, lendirname, opendirid, ierror)
```

- `dirname` (Input) Character. The directory name.
- `lendirname` (Input) INTEGER(4). The length of `dirname` string.
opendirid  (Output) INTEGER(4). The returned ID for the directory.
ierror   (Output) INTEGER(4). The error status.
        If successful, ierror is set to zero; otherwise, an error code.

This subroutine opens a directory pointed to by the dirname argument and returns the ID of
the directory into opendirid. After the call, this ID can be used by functions PXFREADDIR,
PXFREWINDDIR, PXFCLOSEDIR.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFPATHCONF
POSIX Subroutine: Gets the value for a
configuration option of an opened file.

Module
USE IFPOSIX

Syntax
CALL PXFPATHCONF (path,ilen,name,ival,ierror)

path        (Input) Character. The path to the opened file.
ilen       (Input) INTEGER(4). The length of path.
name       (Input) INTEGER(4). The configurable option.
ival       (Input) INTEGER(4). The value of the configurable option.
ierror    (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFPATHCONF subroutine gets a value for the configuration option named for the opened
file with path path.
The configuration option, defined in `name`, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>Returns the maximum number of links to the file. If <code>path</code> refers to a directory, then the value applies to the whole directory.</td>
</tr>
<tr>
<td>_PC_MAX_CANON¹</td>
<td>Returns the maximum length of a formatted input line; the <code>path</code> must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_MAX_INPUT¹</td>
<td>Returns the maximum length of an input line; the <code>path</code> must refer to a terminal.</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>Returns the maximum length of a filename in <code>path</code> that the process is allowed to create.</td>
</tr>
<tr>
<td>_PC_PATH_MAX</td>
<td>Returns the maximum length of a relative pathname when <code>path</code> is the current working directory.</td>
</tr>
<tr>
<td>_PC_PIPE_BUF</td>
<td>Returns the size of the pipe buffer; the <code>path</code> must refer to a FIFO.</td>
</tr>
<tr>
<td>_PC_CHOWN_RESTRICTED¹</td>
<td>Returns nonzero if PXFCHOWN may not be used on this file. If <code>path</code> refers to a directory, then this applies to all files in that directory.</td>
</tr>
<tr>
<td>_PC_NO_TRUNC¹</td>
<td>Returns nonzero if accessing filenames longer than <code>_POSIX_NAME_MAX</code> will generate an error.</td>
</tr>
<tr>
<td>_PC_VDISABLE¹</td>
<td>Returns nonzero if special character processing can be disabled; the <code>path</code> must refer to a terminal.</td>
</tr>
</tbody>
</table>

¹L*X, M*X
On Linux* and Mac OS* X systems, the corresponding macros are defined in <unistd.h>. The values for name can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in <unistd.h>. The following table shows the corresponding macro names for the above constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Corresponding Macro</th>
</tr>
</thead>
<tbody>
<tr>
<td>_PC_LINK_MAX</td>
<td>_POSIX_LINK_MAX</td>
</tr>
<tr>
<td>_PC_MAX_CANON</td>
<td>_POSIX_MAX_CANON</td>
</tr>
<tr>
<td>_PC_MAX_INPUT</td>
<td>_POSIX_MAX_INPUT</td>
</tr>
<tr>
<td>_PC_NAME_MAX</td>
<td>_POSIX_NAME_MAX</td>
</tr>
<tr>

**PXFPause**

**POSIX Subroutine:** Suspends process execution.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFPause (ierror)
ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFPAUSE subroutine causes the invoking process (or thread) to sleep until a signal is received that either terminates it or causes it to call a signal-catching function.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFPIPE**

*POSIX Subroutine: Creates a communications pipe between two processes.*

**Module**
USE IFPOSIX

**Syntax**
CALL PXFPIPE (ireadfd, iwritefd, ierror)

ireadfd  (Output) INTEGER(4). The file descriptor for reading.
iwritefd (Output) INTEGER(4). The file descriptor for writing.
ierror   (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFPIPE subroutine returns a pair of file descriptors, pointing to a pipe inode, and places them into ireadfd for reading and into iwritefd for writing.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFPOSIXIO**

*POSIX Subroutine: Sets the current value of the POSIX I/O flag.*

**Module**
USE IFPOSIX
Syntax

CALL PXFPOSIXIO (new, old, ierror)

new          (Input) INTEGER(4). The new value for the POSIX I/O flag.
old          (Output) INTEGER(4). The previous value of the POSIX I/O flag.
ierror       (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

This subroutine sets the current value of the Fortran POSIX I/O flag and returns the previous value of the flag. The initial state of the POSIX I/O flag is unspecified.

If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is 1, the unit is accessed as if the records are newline delimited, even if the file does not contain records that are delimited by a new line character.

If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is zero, a connection to a file descriptor is not assumed and the records in the file are not required to be accessed as if they are newline delimited.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFPUTC

POSIX Subroutine: Outputs a character to logical unit 6 (stdout).

Module

USE IFPOSIX

Syntax

CALL PXFPUTC (ch, ierror)

ch          (Input) Character. The character to be written.
ierror       (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.
Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

• PXFGETC

PXFREAD

**POSIX Subroutine: Reads from a file.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFREAD (ifildes, buf, nbyte, nread, ierror)

*ifildes* (Input) INTEGER(4). The file descriptor of the file to be read from.

*buf* (Output) Character. The buffer that stores the data read from the file.

*nbyte* (Input) INTEGER(4). The number of bytes to read.

*nread* (Output) INTEGER(4). The number of bytes that were read.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFREAD subroutine reads *nbyte* bytes from the file specified by *ifildes* into memory in *buf*. The subroutine returns the total number of bytes read into *nread*. If no error occurs, the value of *nread* will equal the value of *nbyte*.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

• O to P
• PXFWRITE
PXFREADDR

**POSIX Subroutine:** Reads the current directory entry.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFREADDR (idirid, jdirent, ierror)

- **idirid**  (Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.
- **jdirent**  (Output) INTEGER(4). A handle of structure dirent.
- **ierror**  (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The PXFREADDR subroutine reads the entry of the directory associated with **idirid** into the structure associated with handle **jdirent**.

**NOTE.** To get a handle for an instance of the dirent structure, use PXFSTRUCTCREATE with the string 'dirent' for the structure name.

PXFRENAME

**POSIX Subroutine:** Changes the name of a file.

**Module**

USE IFPOSIX
**Syntax**

CALL PXFRENAME (old, lenold, new, lennew, ierror)

- **old** (Input) Character. The name of the file to be renamed.
- **lenold** (Input) INTEGER(4). The length of *old* string.
- **new** (Input) Character. The new file name.
- **lennew** (Input) INTEGER(4). The length of *new* string.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFREWINDDIR**

**POSIX Subroutine:** Resets the position of the stream to the beginning of the directory.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFREWINDDIR (idirid, ierror)

- **idirid** (Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**PXFRMDIR**

**POSIX Subroutine:** Removes a directory.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFRMDIR (path, ilen, ierror)

- path (Input) Character. The directory to be removed. It must be empty.
- ilen (Input) INTEGER(4). The length of path string.
- ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**See Also**

- O to P
- PXFMKDIR
- PXFCHDIR

**PXFSETENV**

**POSIX Subroutine:** Adds a new environment variable or sets the value of an environment variable.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSETENV (name, lenname, new, lennew, ioverwrite, ierror)

- name (Input) Character. The name of the environment variable.
- lenname (Input) INTEGER(4). The length of name.
- new (Input) Character. The value of the environment variable.
lennew (Input) INTEGER(4). The length of new.

ioverwrite (Input) INTEGER(4). A flag indicating whether to change the value of the environment variable if it exists.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

If name does not exist, PXFSETENV adds it with value new.

If name exists, PXFSETENV sets its value to new if ioverwrite is a nonzero number. If ioverwrite is zero, the value of name is not changed.

If lennew is equal to zero, PXFSETENV sets the value of the environment variable to a string equal to new after removing any leading or trailing blanks.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

program test2
use ifposix
character*10 name, new
integer lenname, lennew, ioverwrite, ierror
name = "FOR_NEW"
lenname = 7
new = "ON"
lennew = 2
ioverwrite = 1
CALL PXFSETENV (name, lenname, new, lennew, ioverwrite, ierror)
print *, "name= ", name
print *, "lenname= ", lenname
print *, "new= ", lenname
print *, "lennew= ", lenname
print *, "ierror= ", ierror
end

• O to P
• PXFGETENV

PXFSETGID (L*X, M*X)

POSIX Subroutine: Sets the effective group ID of the current process.

Module

USE IFPOSIX

Syntax

CALL PXFSETGID (igid,ierror)
igid  (Input) INTEGER(4). The group ID.

ierror  (Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.
If the caller is the superuser, the real and saved group ID's are also set. This feature allows a program other than root to drop all of its group privileges, do some un-privileged work, and then re-engage the original effective group ID in a secure manner.

CAUTION. If the user is root then special care must be taken. PXFSETGID checks the effective gid of the caller. If it is the superuser, all process-related group ID's are set to gid. After this has occurred, it is impossible for the program to regain root privileges.

See Also
• O to P
• PXFGETGID

PXFSETPGID(L*X, M*X)
POSIX Subroutine: Sets the process group ID.

Module
USE IFPOSIX

Syntax
CALL PXFSETPGID (ipid, ipgid, ierror)

ipid  (Input) INTEGER(4). The process group ID to change.

ipgid  (Input) INTEGER(4). The new process group ID.

ierror  (Output) INTEGER(4). The error status.
If successful, ierror is set to zero; otherwise, an error code.

The PXFSETPGID subroutine sets the process group ID of the process specified by ipid to ipgid.

If ipid is zero, the process ID of the current process is used. If ipgid is zero, the process ID of the process specified by ipid is used.
PXFSETPGID can be used to move a process from one process group to another, but both process groups must be part of the same session. In this case, ipgid specifies an existing process group to be joined and the session ID of that group must match the session ID of the joining process.

**PXFSETSID (L*+X, M*X)**  
*POSIX Subroutine: Creates a session and sets the process group ID.*

**Module**  
USE IFPOSIX

**Syntax**

CALL PXFSETSID (isid,ierror)

*isid*  
(Output) INTEGER(4). The session ID.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSETSID subroutine creates a new session if the calling process is not a process group leader.

The calling process is the leader of the new session and the process group leader for the new process group. The calling process has no controlling terminal.

The process group ID and session ID of the calling process are set to the PID of the calling process. The calling process will be the only process in this new process group and in this new session.

**PXFSETUID (L*+X, M*X)**  
*POSIX Subroutine: Sets the effective user ID of the current process.*

**Module**  
USE IFPOSIX

**Syntax**

CALL PXFSETUID (iuid,ierror)

*iuid*  
(Output) INTEGER(4). The session ID.
ierror \hspace{1cm} \text{(Output) INTEGER(4). The user status.}

If successful, \textit{ierror} is set to zero; otherwise, an error code.

If the effective user ID of the caller is root, the real and saved user ID's are also set. This feature allows a program other than root to drop all of its user privileges, do some un-privileged work, and then re-engage the original effective user ID in a secure manner.

\textbf{CAUTION.} If the user is root then special care must be taken. PXFSETUID checks the effective uid of the caller. If it is the superuser, all process-related user ID's are set to \texttt{uid}. After this has occurred, it is impossible for the program to regain root privileges.

\textbf{See Also}
- O to P
- PXFGETUID

\textbf{PXFSIGACTION}

\textit{POSIX Subroutine:} Changes the action associated with a specific signal. It can also be used to examine the action of a signal.

\textbf{Module}
USE IFPOSIX

\textbf{Syntax}
CALL PXFSIGACTION (isig,jsigact,josigact,ierror)

\textit{isig} \hspace{1cm} \text{(Input) INTEGER(4). The signal number whose action should be changed.}

\textit{jsigact} \hspace{1cm} \text{(Input) INTEGER(4). A handle of structure \texttt{sigaction}. Specifies the new action for signal \texttt{isig}.}

\textit{josigact} \hspace{1cm} \text{(Output) INTEGER(4). A handle of structure \texttt{sigaction}. Stores the previous action for signal \texttt{isig}.}

\textit{ierror} \hspace{1cm} \text{(Output) INTEGER(4). The error status.}

If successful, \textit{ierror} is set to zero; otherwise, an error code.

The signal specified in \textit{isig} can be any valid signal except \texttt{SIGKILL} and \texttt{SIGSTOP}. 
If \texttt{jsigact} is nonzero, the new action for signal \texttt{isig} is installed from the structure associated with handle \texttt{jsigact}. If \texttt{josigact} is nonzero, the previous action of the specified signal is saved in the structure associated with handle \texttt{josigact} where it can be examined.

On Windows* systems, PXFSIGACTION ignores the fields \texttt{sa_mask} and \texttt{sa_flags} in structure \texttt{sigaction}.

\begin{center}
\textbf{NOTE.} To get a handle for an instance of the \texttt{sigaction} structure, use \texttt{PXFSTRUCTCREATE} with the string ‘sigaction’ for the structure name.
\end{center}

\section*{Compatibility}
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

\section*{See Also}
\begin{itemize}
  \item O to P
  \item \texttt{PXFSTRUCTCREATE}
\end{itemize}

\section*{PXFSIGADDSET (L*X, M*X)}
\textbf{POSIX Subroutine: Adds a signal to the signal set.}

\section*{Module}
\texttt{USE IFPOSIX}

\section*{Syntax}
\texttt{CALL PXFSIGADDSET (jsigset, isigno, ierror)}

\begin{itemize}
  \item \texttt{jsigset} (Input) INTEGER(4). A handle of structure \texttt{sigset}. This is the set to add the signal to.
  \item \texttt{isigno} (Input) INTEGER(4). The signal number to add to the set.
  \item \texttt{ierror} (Output) INTEGER(4). The error status.
\end{itemize}

\textbf{If successful, \texttt{ierror} is set to zero; otherwise, an error code.}

The PXFSIGADDSET subroutine adds signal number \texttt{isigno} to the set of signals associated with handle \texttt{jsigset}. This set of signals is used by PXFSIGACTION as field \texttt{sa_mask} in structure \texttt{sigaction}. It defines the set of signals that will be blocked during execution of the signal handler function (the field \texttt{sa_handler} in structure \texttt{sigaction}).
On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

**NOTE.** To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

**See Also**
- O to P
- PXFSTRUCTCREATE
- PXFSIGDELSET
- PXFSIGACTION

**PXFSIGDELSET (L*X, M*X)**

**POSIX Subroutine:** Deletes a signal from the signal set.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSIGDELSET (jsigset, isigno, ierror)

- **jsigset** (Input) INTEGER(4). A handle of structure sigset. This is the set to delete the signal from.
- **isigno** (Input) INTEGER(4). The signal number to delete from the set.
- **ierror** (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSIGDELSET subroutine removes signal number isigno from the set of signals associated with handle jsigset. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

**NOTE.** To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.
See Also

- O to P
- PXFSTRUCTCREATE
- PXFSIGADDSET
- PXFSIGACTION

**PXFSIGEMPTYSET (L*X, M*X)**

*POSIX Subroutine: Empties a signal set.*

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSIGEMPTYSET (jsigset, ierror)

- **jsigset** (Input) INTEGER(4). A handle of structure `sigset`. This is the set to empty.
- **ierror** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, nonzero.

The PXFSIGEMPTYSET subroutine initializes the signal set associated with handle `jsigset` to empty; all signals are excluded from the set. This set of signals is used by PXFSIGACTION as field `sa_mask` in structure `sigaction`. It defines the set of signals that will be blocked during execution of the signal handler function (the field `sa_handler` in structure `sigaction`).

On Windows* systems, PXFSIGACTION ignores the field `sa_mask` in structure `sigaction`.

**NOTE.** To get a handle for an instance of the `sigset` structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

- O to P
- PXFSTRUCTCREATE
- PXFSIGFILLSET
- PXFSIGACTION
**PXFSIGFILLSET (L*X, M*X)**

**POSIX Subroutine: Fills a signal set.**

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSIGFILLSET (jsigset, ierror)

- **jsigset** (Input) INTEGER(4). A handle of structure sigset. This is the set to fill.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSIGFILLSET subroutine initializes the signal set associated with handle *jsigset* to full; all signals are included into the set. This set of signals is used by PXFSIGACTION as field *sa_mask* in structure *sigaction*. It defines the set of signals that will be blocked during execution of the signal handler function (the field *sa_handler* in structure *sigaction*).

On Windows* systems, PXFSIGACTION ignores the field *sa_mask* in structure *sigaction*.

---

**NOTE.** To get a handle for an instance of the *sigset* structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

---

- PXFSTRUCTCREATE
- PXFSIGEMPTYSET
- PXFSIGACTION

**PXFSIGISMEMBER (L*X, M*X)**

**POSIX Subroutine: Tests whether a signal is a member of a signal set.**

**Module**

USE IFPOSIX
Syntax
CALL PXFSIGISMEMBER (jsignalset, isigno, ismember, ierror)

jsignalset (Input) INTEGER(4). A handle of structure sigset. This is the set the signal will be tested in.
isigno (Input) INTEGER(4). The signal number to test for membership.
ismember (Output) Logical. The returned result.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFSIGISMEMBER subroutine tests whether isigno is a member of the set associated with handle jsignalset. If the signal is a member of the set, ismember is set to .TRUE.; otherwise, .FALSE.. This set of signals is used by PXFSIGACTION as field sa_mask in structure sigaction. It defines the set of signals that will be blocked during execution of the signal handler function (the field sa_handler in structure sigaction).

On Windows* systems, PXFSIGACTION ignores the field sa_mask in structure sigaction.

**NOTE.** To get a handle for an instance of the sigset structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

- O to P
- PXFSTRUCTCREATE
- PXFSIGACTION

PXFSIGPENDING (L*X, M*X)

**POSIX Subroutine:** Examines pending signals.

Module
USE IFPOSIX

Syntax
CALL PXFSIGPENDING (jsignalset, ierror)
The PXFSIGPENDING subroutine is used to examine pending signals (ones that have been raised while blocked). The signal mask of the pending signals is stored in the signal set associated with handle `jsigset`.

**PXFSIGPROCMASK (L*X, M*X)**

**POSIX Subroutine:** Changes the list of currently blocked signals.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSIGPROCMASK (ihow, jsigset, josigset, ierror)

- `ihow` (Input) INTEGER(4). Defines the action for `jsigset`.
- `jsigset` (Input) INTEGER(4). A handle of structure `sigset`. The signals to examine.
- `josigset` (Input) INTEGER(4). A handle of structure `sigset`. Stores the previous mask of blocked signals.
- `ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The argument `ihow` indicates the way in which the set is to be changed, and consists of one of the following constant names:

<table>
<thead>
<tr>
<th>Constant 1</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIG_BLOCK</td>
<td>The resulting set of blocked signals will be the union of the current signal set and the <code>jsigset</code> signal set.</td>
</tr>
<tr>
<td>Constant</td>
<td>Action</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIG_UNBLOCK</td>
<td>The resulting set of blocked signals will be the current set of blocked signals with the signals in $jsigset$ removed. It is legal to attempt to unblock a signal that is not blocked.</td>
</tr>
<tr>
<td>SIG_SETMASK</td>
<td>The resulting set of blocked signals will be the $jsigset$ signal set.</td>
</tr>
</tbody>
</table>

1These names can be used in PXFCONST or IPXFCONST.

If $josigset$ is non-zero, the previous value of the signal mask is stored in the structure associated with handle $josigset$.

See Also
- O to P
- IPXFCONST
- PXFCONST

**PXFSIGSUSPEND (L*X, M*X)**

**POSIX Subroutine:** Suspends the process until a signal is received.

Module
USE IFPOSIX

Syntax
CALL PXFSIGSUSPEND ($jsigset, ierror$)

$jsigset$  (Input) INTEGER(4). A handle of structure sigset. Specifies a set of signals.
ierror   (Output) INTEGER(4). The error status.

If successful, $ierror$ is set to zero; otherwise, an error code.
PXFSIGSUSPEND temporarily replaces the signal mask for the process with that given by the structure associated with the \textit{jsigset} handle; it then suspends the process until a signal is received.

**PXFSLEEP**

\textbf{POSIX Subroutine: Forces the process to sleep.}

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSLEEP (iseconds, isecleft, ierror)

- \textit{iseconds} \hspace{1cm} (Input) INTEGER(4). The number of seconds to sleep.
- \textit{isecleft} \hspace{1cm} (Output) INTEGER(4). The number of seconds left to sleep.
- \textit{ierror} \hspace{1cm} (Output) INTEGER(4). The error status.

If successful, \textit{ierror} is set to zero; otherwise, an error code.

The PXFSLEEP subroutine forces the current process to sleep until \textit{seconds} \textit{iseconds} have elapsed or a signal arrives that cannot be ignored.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFSTAT**

\textbf{POSIX Subroutine: Gets a file's status information.}

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSTAT (path, llen, jstat, ierror)

- \textit{path} \hspace{1cm} (Input) Character. The path to the file.
- \textit{llen} \hspace{1cm} (Input) INTEGER(4). The length of \textit{path} string.
- \textit{jstat} \hspace{1cm} (Input) INTEGER(4). A handle of structure \textit{stat}. 
**ierror**

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSTAT subroutine puts the status information for the file specified by path into the structure associated with handle *jstat*.

**NOTE.** To get a handle for an instance of the *stat* structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

### Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

### See Also

- O to P
- PXFSTRUCTCREATE

### PXFSTRUCTCOPY

**POSIX Subroutine:** Copies the contents of one structure to another.

### Module

USE IFPOSIX

### Syntax

CALL PXFSTRUCTCOPY (structname, jhandle1, jhandle2, ierror)

*structname*  
(Input) Character. The name of the structure.

*jhandle1*  
(Input) INTEGER(4). A handle to the structure to be copied.

*jhandle2*  
(Input) INTEGER(4). A handle to the structure that will receive the copy.

*ierror*  
(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

### Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example
See the example in PXFSTRUCTCREATE

PXFSTRUCTCREATE

POSIX Subroutine: Creates an instance of the specified structure.

Module
USE IFPOSIX

Syntax
CALL PXFSTRUCTCREATE (structname, jhandle, ierror)

structname (Input) Character. The name of the structure. As for any character string, the name must be specified in single or double quotes; for example, the structure sigaction would be specified as 'sigaction'. (For more information on available structures, see below.)

jhandle (Output) INTEGER(4). The handle of the newly-created structure.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

If your application passes information to the system, you should call one of the PXF(type)SET subroutines. If your application needs to get information from the structure, you should call one of the PXF(type)GET subroutines.

The following table shows:

- The structures that are available in the Fortran POSIX library
- The fields within each structure
- The subroutines you must use to access the structure fields

PXFSTRUCTFREE
POSIX Subroutine: Deletes the instance of a structure.

Module
USE IFPOSIX

Syntax
CALL PXFSTRUCTFREE (jhandle,ierror)
    jhandle (Input) INTEGER(4). The handle of a structure.
    ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
The PXFSTRUCTFREE subroutine deletes the instance of the structure associated with handle jhandle.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
See the example in PXFSTRUCTCREATE, the example in PXFTIMES
**PXFSYSCONF**

**POSIX Subroutine:** Gets values for system limits or options.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFSYSCONF (name, ival, ierror)

- **name** (Input) INTEGER(4). The system option you want information about.
- **ival** (Output) INTEGER(4). The returned value.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFSYSCONF lets you determine values for system limits or system options at runtime.

The value for *name* can be any of the following constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_SC_ARG_MAX1</td>
<td>Indicates the maximum length of the arguments to the PXFEXEC family of routines.</td>
</tr>
<tr>
<td>_SC_CHILD_MAX1</td>
<td>Indicates the number of simultaneous processes per user ID.</td>
</tr>
<tr>
<td>_SC_CLK_TCK</td>
<td>Indicates the number of clock ticks per second.</td>
</tr>
<tr>
<td>_SC_STREAM_MAX2</td>
<td>Indicates the maximum number of streams that a process can have open at any time.</td>
</tr>
<tr>
<td>_SC_TZNAME_MAX</td>
<td>Indicates the maximum number of bytes in a timezone name.</td>
</tr>
<tr>
<td>_SC_OPEN_MAX</td>
<td>Indicates the maximum number of files that a process can have open at any time.</td>
</tr>
<tr>
<td>Constant</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>_SC_JOB_CONTROL^1</td>
<td>Indicates whether POSIX-style job control is supported.</td>
</tr>
<tr>
<td>_SC_SAVED_IDS^1</td>
<td>Indicates whether a process has a saved set-user-ID and a saved set-group-ID.</td>
</tr>
<tr>
<td>_SC_VERSION^1</td>
<td>Indicates the year and month the POSIX.1 standard was approved in the format YYYYMM; the value 199009L indicates the most recent revision, 1990.</td>
</tr>
<tr>
<td>_SC_BC_BASE_MAX^1</td>
<td>Indicates the maximum obase value accepted by the bc(1) utility.</td>
</tr>
<tr>
<td>_SC_BC_DIM_MAX^1</td>
<td>Indicates the maximum value of elements that bc(1) permits in an array.</td>
</tr>
<tr>
<td>_SC_BC_SCALE_MAX^1</td>
<td>Indicates the maximum scale value allowed by bc(1).</td>
</tr>
<tr>
<td>_SC_BC_STRING_MAX^1</td>
<td>Indicates the maximum length of a string accepted by bc(1).</td>
</tr>
<tr>
<td>_SC_COLL_WEIGHTS_MAX^1</td>
<td>Indicates the maximum numbers of weights that can be assigned to an entry of the LC_COLLATE order keyword in the locale definition file.</td>
</tr>
<tr>
<td>_SC_EXPR_NEST_MAX^1,3</td>
<td>Indicates the maximum number of expressions that can be nested within parentheses by expr(1).</td>
</tr>
<tr>
<td>_SC_LINE_MAX^1</td>
<td>Indicates the maximum length of a utility's input line length, either from standard input or from a file. This includes the length for a trailing newline.</td>
</tr>
<tr>
<td>Constant</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>_SC_RE_DUP_MAX(^1)</td>
<td>Indicates the maximum number of repeated occurrences of a regular expression when the interval notation ({m,n}) is used.</td>
</tr>
<tr>
<td>_SC_2_VERSION(^1)</td>
<td>Indicates the version of the POSIX.2 standard; it is in the format YYYYMM.</td>
</tr>
<tr>
<td>_SC_2_DEV(^1)</td>
<td>Indicates whether the POSIX.2 C language development facilities are supported.</td>
</tr>
<tr>
<td>_SC_2_FORT_DEV(^1)</td>
<td>Indicates whether the POSIX.2 FORTRAN language development utilities are supported.</td>
</tr>
<tr>
<td>_SC_2_FORT_RUN(^1)</td>
<td>Indicates whether the POSIX.2 FORTRAN runtime utilities are supported.</td>
</tr>
<tr>
<td>_SC_2_LOCALEDEF(^1)</td>
<td>Indicates whether the POSIX.2 creation of locates via localedef(1) is supported.</td>
</tr>
<tr>
<td>_SC_2_SW_DEV(^1)</td>
<td>Indicates whether the POSIX.2 software development utilities option is supported.</td>
</tr>
<tr>
<td>_SC_PAGESIZE (or _SC_PAGE_SIZE)</td>
<td>Indicates the size of a page (in bytes).</td>
</tr>
<tr>
<td>_SC_PHYS_PAGES(^4)</td>
<td>Indicates the number of pages of physical memory. Note that it is possible for the product of this value and the value of _SC_PAGE_SIZE to overflow.</td>
</tr>
<tr>
<td>_SC_AVPHYS_PAGES(^4)</td>
<td>Indicates the number of currently available pages of physical memory.</td>
</tr>
</tbody>
</table>

\(^1\) L*X only
\(^2\) The corresponding POSIX macro is STREAM_MAX.
\(^3\) The corresponding POSIX macro is EXPR_NEST_MAX.
\(^4\) L*X, W*32, W*64
The corresponding macros are defined in `<bits/confname.h>` on Linux* systems; `<unistd.h>` on Mac OS* X systems. The values for argument `name` can be obtained by using PXFCONST or IPXFCONST when passing the string names of predefined macros in the appropriate .h file.

PXFTCDRAIN (L*X, M*X)

**POSIX Subroutine:** Waits until all output written has been transmitted.

Module
USE IFPOSIX

Syntax
CALL PXFTCDRAIN (ifildes, ierror)

ifildes (Input) INTEGER(4). The file descriptor associated with the terminal.

ierror (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

PXFTCFLOW (L*X, M*X)

**POSIX Subroutine:** Suspends the transmission or reception of data.

Module
USE IFPOSIX

Syntax
CALL PXFTCFLOW (ifildes, iaction, ierror)

ifildes (Input) INTEGER(4). The file descriptor associated with the terminal.

iaction (Input) INTEGER(4). The action to perform.
**ERROR** (Output) INTEGER(4). The error status.

If successful, **ierror** is set to zero; otherwise, an error code.

The **PXFTCFLOW** subroutine suspends or resumes transmission or reception of data from the terminal referred to by **ifildes**. The action performed depends on the value of **iaction**, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant ¹</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCOOFF</td>
<td>Output is suspended.</td>
</tr>
<tr>
<td>TCOON</td>
<td>Output is resumed.</td>
</tr>
<tr>
<td>TCIOFF</td>
<td>A STOP character is transmitted. This should cause the terminal to stop</td>
</tr>
<tr>
<td></td>
<td>transmitting data to the system.</td>
</tr>
<tr>
<td>TCION</td>
<td>A START character is transmitted. This should cause the terminal to</td>
</tr>
<tr>
<td></td>
<td>resume transmitting data to the system.</td>
</tr>
</tbody>
</table>

¹These names can be used in **PXFCONST** or **IPXFCONST**.

**See Also**

- O to P
- **IPXFCONST**
- **PXFCONST**

**PXFTCFLUSH (L*X, M*X)**

**POSIX Subroutine:** Discards terminal input data, output data, or both.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFTCFLUSH (ifildes, iaction, ierror)
ifildes (Input) INTEGER(4). The file descriptor associated with the terminal.

iaction (Input) INTEGER(4). The action to perform.

ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The action performed depends on the value of iaction, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant ¹</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCIFLUSH</td>
<td>Discards all data that has been received but not read.</td>
</tr>
<tr>
<td>TCOFLUSH</td>
<td>Discards all data that has been written but not transmitted.</td>
</tr>
<tr>
<td>TCIOFLUSH</td>
<td>Discards both data received but not read and data written but not transmitted. (Performs TCIFLUSH and TCOFLUSH actions.)</td>
</tr>
</tbody>
</table>

¹These names can be used in PXFCONST or IPXFCONST.

PXFTCGETATTR (L*X, M*X)

POSIX Subroutine: Reads current terminal settings.

Module
USE IFPOSIX

Syntax
CALL PXFTCGETATTR (ifildes, jtermios, ierror)
ifildes  (Input) INTEGER(4). The file descriptor associated with the terminal.

jtermios (Output) INTEGER(4). A handle for structure termios. Stores the terminal settings.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

NOTE. To get a handle for an instance of the termios structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

- O to P
- PXFSTRUCTCREATE
- PXFTCSETATTR

PXFTCGETPGRP (L*X, M*X)

POSIX Subroutine: Gets the foreground process group ID associated with the terminal.

Module

USE IFPOSIX

Syntax

CALL PXFTCGETPGRP (ifildes, ipgid, ierror)

ifildes  (Input) INTEGER(4). The file descriptor associated with the terminal.

ipgid  (Output) INTEGER(4). The returned process group ID.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

See Also

- O to P
- PXFTCSETPGRP
PXFTCSENDBREAK (L*X, M*X)

POSIX Subroutine: Sends a break to the terminal.

Module
USE IFPOSIX

Syntax
CALL PXFTCSENDBREAK (ifildes, iduration, ierror)

ifildes (Input) INTEGER(4). The file descriptor associated with the terminal.
iduration (Input) INTEGER(4). Indicates how long the break should be.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFTCSENDBREAK subroutine sends a break (a '\0' with a framing error) to the terminal associated with ifildes.

PXFTCSETATTR (L*X, M*X)

POSIX Subroutine: Writes new terminal settings.

Module
USE IFPOSIX

Syntax
CALL PXFTCSETATTR (ifildes, ioptacts, jtermios, ierror)

ifildes (Input) INTEGER(4). The file descriptor associated with the terminal.
ioptacts (Input) INTEGER(4). Specifies when the terminal changes take effect.
jtermios (Input) INTEGER(4). A handle for structure termios. Contains the new terminal settings.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.
The PXFTCSETATTR subroutine copies all terminal parameters from structure `termios` into the terminal associated with `ifildes`. When the terminal settings will change depends on the value of `i optacts`, which must be one of the following constant names:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCSANOW</td>
<td>The changes occur immediately.</td>
</tr>
<tr>
<td>TCSADRAIN</td>
<td>The changes occur after all output written to <code>ifildes</code> has been transmitted.</td>
</tr>
<tr>
<td>TCSAFLUSH</td>
<td>The changes occur after all output written to <code>ifildes</code> has been transmitted, and all input that had been received but not read has been discarded.</td>
</tr>
</tbody>
</table>

1 These names can be used in PXFCONST or IPXFCONST.

**NOTE.** To get a handle for an instance of the `termios` structure, use PXFSTRUCTCREATE with the string 'termios' for the structure name.

### See Also
- O to P
- PXFSTRUCTCREATE
- PXFTCGETATTR

### PXFTCSETPGRP (L*X, M*X)

**POSIX Subroutine: Sets the foreground process group ID associated with the terminal.**

**Module**

USE IFPOSIX

**Syntax**

```
CALL PXFTCSETPGRP (ifildes, ipgid, ierror)
```
ifildes  (Input) INTEGER(4). The file descritor associated with the terminal.

ipgid  (Input) INTEGER(4). The foreground process group ID for ifildes.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

See Also
- O to P
- PXFTCGETPGRP

PXFTIME

POSIX Subroutine: Returns the current system time.

Module
USE IFPOSIX

Syntax
CALL PXFTIME (itime, ierror)

itime  (Output) INTEGER(4). The returned system time.

ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFTIME subroutine returns the number of seconds since Epoch (00:00:00 UTC, January 1, 1970).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
See the example in PXFTIMES.
PXFTIMES

POSIX Subroutine: Returns process times.

Module
USE IFPOSIX

Syntax
CALL PXFTIMES (jtms, itime, ierror)

jtms (Output) INTEGER(4). A handle of structure tms.
itime (Output) INTEGER(4). The returned time since system startup.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFTIMES subroutine fills the fields of structure tms associated with handle jtms with components of time that was spent by the current process. The structure fields are:

- tms_utime - User CPU time
- tms_stime - System CPU time
- tms_cutime - User time of child process
- tms_cstime - System time of child process

All members are measured in system clocks. The values can be converted to seconds by dividing by value ival returned from the following call:

PXFSYSCONF(IPXFCONST('_SC_CLK_TCK'), ival, ierror)

User time is the time charged for the execution of user instructions of the calling process. System time is the time charged for execution by the system on behalf of the calling process.

NOTE. To get a handle for an instance of the tms structure, use PXFSTRUCTCREATE with the string 'tms' for the structure name.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFTTYNAM (L*X, M*X)

**POSIX Subroutine:** Gets the terminal pathname.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFTTYNAM (ifildes, s, ilen, ierror)

- **ifildes** (Input) INTEGER(4). The file descriptor associated with the terminal.
- **s** (Output) Character. The returned terminal pathname.
- **ilen** (Output) INTEGER(4). The length of the string stored in s.
- **ierror** (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFUCOMPARE

**POSIX Subroutine:** Compares two unsigned integers.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFUCOMPARE (i1, i2, icmpr, idiff)

- **i1, i2** (Input) INTEGER(4). The two unsigned integers to compare.
- **icmpr** (Output) INTEGER(4). The result of the comparison; one of the following values:
  - `-1` If `i1 < i2`
  - `0` If `i1 = i2`
  - `1` If `i1 > i2`
- **idiff** (Output) INTEGER(4). The absolute value of the difference.
The PXFUCOMPARE subroutine compares two unsigned integers and returns the absolute value of their difference into \textit{idiff}.

\textbf{Compatibility}

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

\textbf{PXFUMASK}

\textit{POSIX Subroutine: Sets a new file creation mask and gets the previous one.}

\textbf{Module}

USE IFPOSIX

\textbf{Syntax}

CALL PXFUMASK (icmask,iprevcmask,ierror)

- \textit{icmask} (Input) INTEGER(4). The new file creation mask.
- \textit{iprevcmask} (Output) INTEGER(4). The previous file creation mask.
- \textit{ierror} (Output) INTEGER(4). The error status.

If successful, \textit{ierror} is set to zero; otherwise, an error code.

\textbf{Compatibility}

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

\textbf{PXFUNAME}

\textit{POSIX Subroutine: Gets the operation system name.}

\textbf{Module}

USE IFPOSIX

\textbf{Syntax}

CALL PXFUNAME (jutsname,ierror)

- \textit{jutsname} (Input) INTEGER(4). A handle of structure \texttt{utsname}.
- \textit{ierror} (Output) INTEGER(4). The error status.
If successful, *ierror* is set to zero; otherwise, an error code.

The PXFUNAME subroutine provides information about the operation system. The information is stored in the structure associated with handle *jutsname*.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

See the example in PXFSTRUCTCREATE

**PXFUNLINK**

**POSIX Subroutine:** Removes a directory entry.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFUNLINK (*path*, *ilen*, *ierror*)

- *path* (Input) Character. The name of the directory entry to remove.
- *ilen* (Input) INTEGER(4). The length of *path* string.
- *ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**PXFUTIME**

**POSIX Subroutine:** Sets file access and modification times.

**Module**

USE IFPOSIX

**Syntax**

CALL PXFUTIME (*path*, *ilen*, *jutimbuf*, *ierror*)
path  (Input) Character. The path to the file.
ilen  (Input) INTEGER(4). The length of path string.
jutimbuf  (Input) INTEGER(4). A handle of structure utimbuf.
ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFUTIME subroutine sets access and modification times for the file pointed to by path.
The time values are retrieved from structure utimbuf.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

PXFWAIT (L*X, M*X)
POSIX Subroutine: Waits for a child process.

Module
USE IFPOSIX

Syntax
CALL PXFWAIT (istat, iretpid, ierror)

istat  (Output) INTEGER(4). The returned status of the child process.
iretpid  (Output) INTEGER(4). The process ID of the stopped child process.
ierror  (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFWAIT subroutine suspends execution of the current process until a child has exited, or
until a signal is delivered whose action terminates the current process or calls a signal handling
routine. If the child has already exited by the time of the call (a "zombie" process), a return is
immediately made. Any system resources used by the child are freed.

The subroutine returns in iretpid the value of the process ID of the child that exited, or zero
if no child was available. The returned value in istat can be used in subroutines
IPXFWEIXSTATUS, IPXFWSTOPSIG, IPXFWTERMSIG, PXFWFEXITED, PXFWIFSIGNALLED, and
PXFWIFSTOPPED.
Example

program t1
use ifposix

integer(4) ipid, istat, ierror, ipid_ret, istat_ret

print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
   print *, "I am a child process"
   print *, "My child's pid is", IPID_RET
   call PXFGETPPID(IPID_RET,IERROR)
   print *, "The pid of my parent is", IPID_RET
   print *, "Now I have exited with code 0xABCD"
call PXFEXIT(Z'ABCD')
else
   print *, "I am a parent process"
   print *, "My parent pid is ", IPID_RET
   print *, "I am creating the process with pid", IPID
   print *, "Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
   print *, "The child with pid ", IPID_RET," has exited"
   if( PXFWIFEXITED(ISTAT) ) then
      print *, "The child exited normally"
      istat_ret = IPXFWEXITSTATUS(ISTAT)
      print 10,"The low byte of the child exit code is", istat_ret
   end if
end if
10 FORMAT (A,Z)

- IPXFWTERMSIG
- PXFWIFEXITED
- PXFWIFSIGNALLED
- PXFWIFSTOPPED

PXFWAITPID (L*X, M*X)

POSIX Subroutine: Waits for a specific PID.

Module

USE IFPOSIX

Syntax

CALL PXFWAITPID (ipid, istat, ioptions, iretpid, ierror)

pipe (Input) INTEGER(4). The PID to wait for. One of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; -1</td>
<td>Specifies to wait for any child process whose process group ID is equal to the absolute value of ipid.</td>
</tr>
<tr>
<td>-1</td>
<td>Specifies to wait for any child process; this is the same behavior as PXFWAIT.</td>
</tr>
<tr>
<td>0</td>
<td>Specifies to wait for any child process whose process group ID is equal to that of the calling process.</td>
</tr>
</tbody>
</table>
Specifies to wait for the child whose process ID is equal to the value of `ipid`.

**Output** INTEGER(4). The returned status of the child process.

**istat**

(Input) INTEGER(4). One or more of the following constant values (which can be passed to PXFCONST or IPXFCONST):

<table>
<thead>
<tr>
<th>Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>WNOHANG</td>
<td>Specifies to return immediately if no child process has exited.</td>
</tr>
<tr>
<td>WUNTRACED</td>
<td>Specifies to return for child processes that have stopped, and whose status has not been reported.</td>
</tr>
</tbody>
</table>

**iretpid**

(Output) INTEGER(4). The PID of the stopped child process.

**ierror**

(Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The PXFWAITPID subroutine suspends execution of the current process until the child specified by `ipid` has exited, or until a signal is delivered whose action terminates the current process or calls a signal handling routine. If the child specified by `ipid` has already exited by the time of the call (a "zombie" process), a return is immediately made. Any system resources used by the child are freed.

The returned value in `istat` can be used in subroutines IPXFWEXITSTATUS, IPXFWSTOPSIG, IPXFWTERMSIG, PXFWIXEXITED, PXFWIFSIGNALLED, and PXFWIFSSTOPPED.

**See Also**

- O to P
- PXFWAIT
- IPXFWEXITSTATUS

- IPXFWTERMSIG
• PXFWIFEXITED
• PXFWIFSIGNalled
• PXFWIFSTOPPED

**PXFWIFEXITED (L^X, M^X)**

**POSIX Function:** Determines if a child process has exited.

**Module**

USE IFPOSIX

**Syntax**

\[
\text{result} = \text{PXFWIFEXITED} (\text{istat})
\]

\*istat\* (Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

**Results**

The result type is logical. The result value is .TRUE. if the child process has exited normally; otherwise, .FALSE..

**Example**

program t1

use ifposix

integer(4) ipid, istat, ierror, ipid_ret, istat_ret

print *, "the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET, IERROR)
if(IPID.EQ.0) then
    print *," I am a child process"
    print *," My child's pid is", IPID_RET
    call PXFGETPPID(IPID_RET,IERROR)
    print *," The pid of my parent is",IPID_RET
    print *," Now I have exited with code 0xABCD"
    call PXFEXIT(Z'ABCD')
else
    print *," I am a parent process"
    print *," My parent pid is ", IPID_RET
    print *," I am creating the process with pid", IPID
    print *," Now I am waiting for the end of the child process"
    call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *," The child with pid ", IPID_RET," has exited"
    if( PXFWIFEXITED(ISTAT) ) then
        print *, " The child exited normally"
        istat_ret = IPXFWEXITSTATUS(ISTAT)
        print 10, " The low byte of the child exit code is", istat_ret
    end if
end if
10 FORMAT (A,Z)
end program

See Also
- O to P
- PXFWIFSIGNALED
- PXFWIFSTOPPED
PXFWIFSIGNALED (L*X, M*X)

POSIX Function: Determines if a child process has exited because of a signal.

Module
USE IFPOSIX

Syntax
result = PXFWIFSIGNALED (istat)

istat (Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

Results
The result type is logical. The result value is .TRUE. if the child process has exited because of a signal that was not caught; otherwise, .FALSE..

See Also
• O to P
• PXFWIFEXITED
• PXFWIFSTOPPED

PXFWIFSTOPPED (L*X, M*X)

POSIX Function: Determines if a child process has stopped.

Module
USE IFPOSIX

Syntax
result = PXFWIFSTOPPED (istat)

istat (Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).
Results
The result type is logical. The result value is .TRUE. if the child process has stopped; otherwise, .FALSE..

See Also
• O to P
• PXFWIFEXITED
• PXFWIFSIGNALED

PXFWRITE

POSIX Subroutine: Writes to a file.

Module
USE IFPOSIX

Syntax
CALL PXFWRITE (ifildes,buf,nbyte,nwritten,ierror)

ifildes (Input) INTEGER(4). The file descriptor for the file to be written to.
buf (Input) Character. The buffer that contains the data to write into the file.
nbyte (Input) INTEGER(4). The number of bytes to write.
nwritten (Output) INTEGER(4). The returned number of bytes written.
ierror (Output) INTEGER(4). The error status.

If successful, ierror is set to zero; otherwise, an error code.

The PXFWRITE subroutine writes nbyte bytes from the storage buf into a file specified by file descriptor ifildes. The subroutine returns the total number of bytes read into nwritten. If no error occurs, the value of nwritten will equal the value of nbyte.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Q to R

**QCMPLX**

*Elemental Intrinsic Function (Specific):* Converts an argument to COMPLEX(16) type. This function cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{QCMPLX}(x[,y])
\]

- \(x\) (Input) Must be of type integer, real, or complex.
- \(y\) (Input; optional) Must be of type integer or real. It must not be present if \(x\) is of type complex.

**Results**

The result type is COMPLEX(16) (or COMPLEX*32).

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If \(y\) is not specified and \(x\) is complex, the result value is CMPLX(REAL(\(x\)), AIMAG(\(x\))).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.

\(\text{QCMPLX}(x, y)\) has the complex value whose real part is REAL(\(x\), kind=16) and whose imaginary part is REAL(\(y\), kind=16).

**Example**

QCMPLX (-3) has the value (-3.0Q0, 0.0Q0).

QCMPLX (4.1, 2.3) has the value (4.1Q0, 2.3Q0).

**See Also**

- Q to R
- CMPLX
- DCMPLX
QEXT

Elemental Intrinsic Function (Generic):
Converts a number to quad precision (REAL(16)) type.

Syntax
result = QEXT (a)

a
(Input) Must be of type integer, real, or complex.

Results
The result type is REAL(16) (REAL*16). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If a is of type REAL(16), the result is the value of the a with no conversion (QEXT(a) = a).

If a is of type integer or real, the result has as much precision of the significant part of a as a REAL(16) value can contain.

If a is of type complex, the result has as much precision of the significant part of the real part of a as a REAL(16) value can contain.

<table>
<thead>
<tr>
<th>Specific Name</th>

**Specific Name** ¹ | **Argument Type** | **Result Type**
---|---|---
REAL(16) | REAL(16) | 
COMPLEX(4) | REAL(16) | 
COMPLEX(8) | REAL(16) | 
COMPLEX(16) | REAL(16) | 

¹These specific functions cannot be passed as actual arguments.

**Example**

QEXT (4) has the value 4.0 (rounded; there are 32 places to the right of the decimal point).

QEXT ((3.4, 2.0)) has the value 3.4 (rounded; there are 32 places to the right of the decimal point).

**QFLOAT**

*Elemental Intrinsic Function (Generic):*

*Converts an integer to quad precision (REAL(16)) type.*

**Syntax**

\[
\text{result} = \text{QFLOAT}(a)
\]

\[a\] (Input) Must be of type integer.

**Results**

The result type is REAL(16) (REAL*16).

Functions that cause conversion of one data type to another type have the same affect as the implied conversion in assignment statements.

**Example**

QFLOAT (~4) has the value ~4.0 (rounded; there are 32 places to the right of the decimal point).
QNUM

**Elemental Intrinsic Function (Specific):** Converts a character string to a REAL(16) value. This function cannot be passed as an actual argument.

**Syntax**

```
result = QNUM (i)
```

*i*  (Input) Must be of type character.

**Results**

The result type is REAL(16). The result value is the real value represented by the character string *i*.

**Example**

QNUM ("-174.23") has the value -174.23 of type REAL(16).

QRANSET

**Portability Subroutine:** Sets the seed for a sequence of pseudo-random numbers.

**Module**

USE IFPORT

**Syntax**

```
CALL QRANSET (rseed)
```

*rseed*  (Input) INTEGER(4). The reset value for the seed.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**QREAL**

*Elemental Intrinsic Function (Specific):*
Converting the real part of a COMPLEX(16) argument
to REAL(16) type. This is a specific function that
has no generic function associated with it. It cannot
be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{QREAL} (a)
\]

\(a\) (Input) Must be of type COMPLEX(16) (or COMPLEX*32).

**Results**
The result type is quad-precision real (REAL(16) or REAL*16).

**Example**
QREAL ((2.0q0, 3.0q0)) has the value 2.0q0.

**See Also**
- Q to R
- REAL
- DREAL

**QSORT**

*Portability Subroutine: Performs a quick sort on
an array of rank one.*

**Module**

USE IFPORT

**Syntax**

CALL QSORT (array, len, isize, compar)

\(\)array (Input) Any type. One-dimensional array to be sorted.
If the data type does not conform to one of the predefined
interfaces for QSORT, you may have to create a new interface (see
below).
\textbf{len} \hspace{2cm} (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. Number of elements in \textit{array}.

\textbf{isize} \hspace{2cm} (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. Size, in bytes, of a single element of \textit{array}:

- 4 if array is of type REAL(4)
- 8 if array is of type REAL(8) or complex
- 16 if array is of type COMPLEX(8)

\textbf{compar} \hspace{2cm} (Input) INTEGER(2). Name of a user-defined ordering function that determines sort order. The type declaration of \textit{compar} takes the form:

\begin{verbatim}
INTEGER(2) FUNCTION compar(arg1, arg2)
where arg1 and arg2 have the same type as array (above). Once you have created an ordering scheme, implement your sorting function so that it returns the following:

- Negative if arg1 should precede arg2
- Zero if arg1 is equivalent to arg2
- Positive if arg1 should follow arg2
\end{verbatim}

Dummy argument \textit{compar} must be declared as external. In place of an INTEGER kind, you can specify the constant SIZEOF\_SIZE\_T, defined in IFPORT.F90, for argument \textit{len} or \textit{isize}. Use of this constant ensures correct compilation.

\textbf{NOTE.} If you use QSORT with different data types, your program must have a USE IFPORT statement so that all the calls work correctly. In addition, if you wish to use QSORT with a derived type or a type that is not in the predefined interfaces, you must include an overload for the generic subroutine QSORT. Examples of how to do this are in the portability module's source file, IFPORT.F90.

\textbf{Compatibility}

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

PROGRAM SORTQ
  USE IFPORT
  integer(2), external :: cmp_function
  integer(2) insort(26), i
  integer (SIZEOF_SIZE_T) array_len, array_size
  array_len = 26
  array_size = 2
  do i=90,65,-1
    insort(i-64)=91 - i
  end do
  print *, "Before: ", insort
  CALL qsort(insort,array_len,array_size,cmp_function)
  print *, 'After: ', insort
END

! 

integer(2) function cmp_function(a1, a2)
  integer(2) a1, a2
  cmp_function=a1-a2
end function

RADIX

_Inquiry Intrinsic Function (Generic):_ Returns the base of the model representing numbers of the same type and kind as the argument.

_Syntax_

result = RADIX (x)
Must be of type integer or real; it can be scalar or array valued.

**Results**

The result is a scalar of type default integer. For an integer argument, the result has the value \( r \) (as defined in Model for Integer Data). For a real argument, the result has the value \( b \) (as defined in Model for Real Data).

**Example**

If \( X \) is a REAL(4) value, \( \text{RADIX} (X) \) has the value 2.

**See Also**

- Q to R
- DIGITS
- EXPONENT
- FRACTION
- Data Representation Models

**RAISEQQ**

*Portability Function*: Sends a signal to the executing program.

**Module**

USE IFPORT

**Syntax**

```fortran
result = RAISEQQ (sig)
```

\( sig \) (Input) INTEGER(4). Signal to raise. One of the following constants (defined in IFPORT.F90):

- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+C signal
- SIG$SEGV - Illegal storage access
• SIG$TERM - Termination request

If you do not install a signal handler (with SIGNALQQ, for example), when a signal occurs the system by default terminates the program with exit code 3.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.
If a signal-handling routine for \( \text{sig} \) has been installed by a prior call to SIGNALQQ, RAISEQQ causes that routine to be executed. If no handler routine has been installed, the system terminates the program (the default action).

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

See Also
• Q to R
• SIGNALQQ
• SIGNAL
• KILL

RAN
Nonelemental Intrinsic Function (Specific):
Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax
\[
\text{result} = \text{RAN} \ (i)
\]

\( i \)
(Input; output) Must be an INTEGER(4) variable or array element. It should initially be set to a large, odd integer value. The RAN function stores a value in the argument that is later used to calculate the next random number.
There are no restrictions on the seed, although it should be initialized with different values on separate runs to obtain different random numbers.
Results
The result type is REAL(4). The result is a floating-point number that is uniformly distributed in the range between 0.0 inclusive and 1.0 exclusive. It is set equal to the value associated with the argument \( i \).

RAN is not a pure function.

Example
In RAN (I), if variable I has the value 3, RAN has the value 4.8220158E-05.

See Also
• Q to R
• RANDOM
• RANDOM_NUMBER

RAND, RANDOM
_Portability Functions:_ Return real random numbers in the range 0.0 through 1.0.

Module
USE IFPORT

Syntax
result = RAND ([ iflag])
result = RANDOM (iflag)

iflag (Input) INTEGER(4). Optional for RAND. Controls the way the random number is selected.

Results
The result type is REAL(4). RAND and RANDOM return random numbers in the range 0.0 through 1.0.

<table>
<thead>
<tr>
<th>Value of iflag</th>
<th>Selection process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
</tbody>
</table>
Selection process

The next random number in the sequence is selected.

Otherwise

The generator is reseeded using iflag, restarted, and the first random value is selected.

When RAND is called without an argument, iflag is assumed to be 0.

There is no difference between RAND and RANDOM. Both functions are included to ensure portability of existing code that references one or both of them. The intrinsic functions RANDOM_NUMBER and RANDOM_SEED provide the same functionality.

You can use SRAND to restart the pseudorandom number generator used by RAND.

NOTE. RANDOM is available as a function or subroutine.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

The following example shows how to use both the RANDOM function and the RANDOM subroutine:

use ifport real(4) ranval

!from libifcore.lib

call seed(1995) ! initialize

!also from for_m_irand.c in libfor

call random(ranval) ! get next random number

print *, ranval
!from libifport.lib

ranval = random(1) ! initialize
!
! same

ranval = random(0) ! get next random number

print *,ranval

end

See Also
• Q to R
• RANDOM_NUMBER
• RANDOM_SEED
• SRAND

RANDOM Subroutine

Portability Subroutine: Returns a pseudorandom number greater than or equal to zero and less than one from the uniform distribution.

Module

USE IFPORT

Syntax

CALL RANDOM (ranval)

ranval (Output) REAL(4). Pseudorandom number, 0 < ranval < 1, from the uniform distribution.

A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in IFCORE.F90) to SEED before the first call to RANDOM.
The portability routines DRAND, DRANDM, IRAND, IRANDM, RAN, RAND, and the RANDOM portability function and subroutine use the same algorithms and thus return the same answers. They are all compatible and can be used interchangeably. The algorithm used is a "Prime Modulus M Multiplicative Linear Congruential Generator," a modified version of the random number generator by Park and Miller in "Random Number Generators: Good Ones Are Hard to Find," CACM, October 1988, Vol. 31, No. 10.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
USE IFPORT
REAL(4) ran
CALL SEED(1995)
CALL RANDOM(ran)

The following example shows how to use both the RANDOM subroutine and the RANDOM function:

```fortran
use ifport
real(4) ranval
! from libifcore.lib
call seed(1995) ! initialize
! also from for_m_irand.c in libfor
call random(ranval) ! get next random number
print *,ranval
! from libifport.lib
ranval = random(1) ! initialize
! same
ranval = random(0) ! get next random number
print *,ranval
end
```
See Also

- RANDOM_NUMBER
- SEED
- DRAND and DRANDM
- IRAND and IRANDM
- RAN
- RAND

RANDOM_NUMBER

**Intrinsic Subroutine:** Returns one pseudorandom number or an array of such numbers.

Syntax

```fortran
CALL RANDOM_NUMBER (harvest)
```

harvest (Output) Must be of type real. It can be a scalar or an array variable. It is set to contain pseudorandom numbers from the uniform distribution within the range 0 <= x < 1.

The seed for the pseudorandom number generator used by RANDOM_NUMBER can be set or queried with RANDOM_SEED. If RANDOM_SEED is not used, the processor sets the seed for RANDOM_NUMBER to a processor-dependent value.

The RANDOM_NUMBER generator uses two separate congruential generators together to produce a period of approximately $10^{18}$, and produces real pseudorandom results with a uniform distribution in (0,1). It accepts two integer seeds, the first of which is reduced to the range [1, 2147483562]. The second seed is reduced to the range [1, 2147483398]. This means that the generator effectively uses two 31-bit seeds.

For more information on the algorithm, see the following:

Example

Consider the following:

```fortran
REAL Y, Z (5, 5)
! Initialize Y with a pseudorandom number
CALL RANDOM_NUMBER (HARVEST = Y)
CALL RANDOM_NUMBER (Z)

Y and Z contain uniformly distributed random numbers.
```

The following shows another example:

```fortran
REAL x, array1 (5, 5)
CALL RANDOM_SEED()
CALL RANDOM_NUMBER(x)
CALL RANDOM_NUMBER(array1)
```
Consider also the following:

```fortran
program testrand
  intrinsic random_seed, random_number
  integer size, seed(2), gseed(2), hiseed(2), zseed(2)
  real harvest(10)
  data seed /123456789, 987654321/
  data hiseed /-1, -1/
  data zseed /0, 0/
  call random_seed(SIZE=size)
  print *, "size ", size
  call random_seed(PUT=hiseed(1:size))
  call random_seed(GET=gseed(1:size))
  print *, "hiseed gseed", hiseed, gseed
  call random_seed(PUT=zseed(1:size))
  call random_seed(GET=gseed(1:size))
  print *, "zseed gseed ", zseed, gseed
  call random_seed(PUT=seed(1:size))
  call random_seed(GET=gseed(1:size))
  call random_number(HARVEST=harvest)
  print *, "seed gseed ", seed, gseed
  print *, "harvest"
  print *, harvest
  call random_seed(GET=gseed(1:size))
  print *, "gseed after harvest ", gseed
end program testrand
```

See Also
- Q to R
- RANDOM_SEED
- RANDOM
• SEED
• DRAND and DRANDM
• IRAND and IRANDM
• RAN
• RAND and RANDOM

**RANDOM_SEED**

*Intrinsic Subroutine (Generic):* Changes or queries the seed (starting point) for the pseudorandom number generator used by `RANDOM_NUMBER`. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL RANDOM_SEED ([size] [,put] [,get])
```

- `size` (Output; optional) Must be scalar and of type `integer`. Set to the number of integers (N) that the processor uses to hold the value of the seed.
- `put` (Input; optional) Must be an `integer` array of rank one and size greater than or equal to N. It is used to reset the value of the seed.
- `get` (Output; optional) Must be an `integer` array of rank one and size greater than or equal to N. It is set to the current value of the seed.

No more than one argument can be specified. If no argument is specified, a random number based on the date and time is assigned to the seed.

At run-time, the arguments are examined in the order `size` then `put` then `get`. The first optional argument in this order that is present determines the behavior of the `RANDOM_SEED` call.

You can determine the size of the array the processor uses to store the seed by calling `RANDOM_SEED` with the `size` argument (see the second example below).
Example

Consider the following:

```fortran
CALL RANDOM_SEED ! Processor initializes the
! seed randomly from the date
! and time
CALL RANDOM_SEED (SIZE = M) ! Sets M to N
CALL RANDOM_SEED (PUT = SEED (1 : M)) ! Sets user seed
CALL RANDOM_SEED (GET = OLD (1 : M)) ! Reads current seed
```

The following shows another example:

```fortran
INTEGER I
INTEGER, ALLOCATABLE :: new (:), old(:)
CALL RANDOM_SEED ( ) ! Processor reinitializes the seed
! randomly from the date and time
CALL RANDOM_SEED (SIZE = I) ! I is set to the size of
! the seed array
ALLOCATE (new(I))
ALLOCATE (old(I))
CALL RANDOM_SEED (GET=old(1:I)) ! Gets the current seed
WRITE(*,*) old
new = 5
CALL RANDOM_SEED (PUT=new(1:I)) ! Sets seed from array
! new
END
```

See Also

- Q to R
- RANDOM_NUMBER
- SEED
- SRAND
**RANDU**

*Intrinsic Subroutine (Generic):* Computes a pseudorandom number as a single-precision value. *Intrinsic subroutines cannot be passed as actual arguments.*

**Syntax**

```fortran
CALL RANDU (i1, i2, x)
```

- `i1, i2` *(Input; output)* Must be scalars of type INTEGER(2) or INTEGER(4). They contain the *seed* for computing the random number. These values are updated during the computation so that they contain the updated seed.

- `x` *(Output)* Must be a scalar of type REAL(4). This is where the computed random number is returned.

The result is returned in `x`, which must be of type REAL(4). The result value is a pseudorandom number in the range 0.0 to 1.0. The algorithm for computing the random number value is based on the values for `i1` and `i2`.

The result value is a pseudorandom number in the range 0.0 to 1.0. The algorithm for computing the random number value is based on the values for `i1` and `i2`.

If `i1 = 0` and `i2 = 0`, the generator base is set as follows:

\[ x(n + 1) = 2^{16} + 3 \]

Otherwise, it is set as follows:

\[ x(n + 1) = (2^{16} + 3) \times x(n) \mod 2^{32} \]

The generator base `x(n + 1)` is stored in `i1`, `i2`. The result is `x(n + 1)` scaled to a real value `y(n + 1)`, for `0.0 \leq y(n + 1) < 1`.

**Example**

Consider the following:

```fortran
REAL X
INTEGER(2) I, J
...
CALL RANDU (I, J, X)
```

If `I` and `J` are values 4 and 6, `X` has the value `5.4932479E-04`. 

---

3362
RANF

*Portability Function:* Generates a random number between 0.0 and RAND_MAX.

**Module**

USE IFPORT

**Syntax**

```
result = RANF ( )
```

**Results**

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and RAND_MAX as defined in the C library, normally 0x7FFF 215-1.

The initial seed is set by the following:

```
CALL SRAND(ISEED)
```

where ISEED is type INTEGER(4).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

RANGE

*Inquiry Intrinsic Function (Generic):* Returns the decimal exponent range in the model representing numbers with the same kind parameter as the argument.

**Syntax**

```
result = RANGE (x)
```

x (Input) Must be of type integer, real, or complex; it can be scalar or array valued.

**Results**

The result is a scalar of type default integer.

For an integer argument, the result has the value INT(LOG10( HUGE( x ) ). For information on the integer model, see Model for Integer Data.
For a real or complex argument, the result has the value \( \text{INT} \left( \text{MIN} \left( \log_{10}(\text{HUGE}(x)), -\log_{10}(\text{TINY}(x)) \right) \right) \). For information on the real model, see Model for Real Data.

**Example**

If \( X \) is a REAL(4) value, RANGE (\( X \)) has the value 37. (\( \text{HUGE}(X) = (1 - 2^{-24}) \times 2^{128} \) and \( \text{TINY}(X) = 2^{-126} \))

**See Also**
- Q to R
- HUGE
- TINY

**RANGET**

*Portability Subroutine: Returns the current seed.*

**Module**

USE IFPORT

**Syntax**

```
CALL RANGET (seed)
```

\( seed \) (Output) INTEGER(4). The current seed value.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**RANSET**

*Portability Subroutine: Sets the seed for the random number generator.*

**Module**

USE IFPORT

**Syntax**

```
CALL RANSET (seed)
```

\( seed \) (Input) REAL(4). The reset value for the seed.
Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

READ Statement

Statement: Transfers input data from external
sequential, direct-access, or internal records.

Syntax

Sequential
Formatted:

READ form[, io-list]

Formatted - List-Directed:
READ (eunit, *[, asynchronous] [, id] [, pos] [, iostat] [, err] [, end])
[io-list]
READ *[, io-list]

Formatted - Namelist:
READ (eunit, nml-group[, iostat][, err][, end])

READ nml

Unformatted:
READ (eunit [, asynchronous] [, id] [, pos] [, iostat][, err][, end]) [io-list]

Direct-Access
Formatted:
READ (eunit, format, rec [, asynchronous] [, id] [, pos] [, iostat] [, err])
[io-list]

Unformatted:
READ (eunit, rec [, asynchronous] [, id] [, pos] [, iostat] [, err]) [io-list]

Internal
READ (iunit, format [, iostat] [, err] [, end]) [io-list]
eunit

Is an external unit specifier, optionally prefaced by UNIT=. UNIT= is required if eunit is not the first specifier in the list.

format

Is a format specifier. It is optionally prefaced by FMT= if format is the second specifier in the list and the first specifier indicates a logical or internal unit specifier without the optional keyword UNIT=.

For internal READs, an asterisk (*) indicates list-directed formatting. For direct-access READs, an asterisk is not permitted.

advance

Is an advance specifier (ADVANCE=c-expr). If the value of c-expr is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.

asynchronous

Is an asynchronous specifier (ASYNCHRONOUS=i-expr). If the value of i-expr is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.

id

Is an id specifier (ID=id-var). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.

pos

Is a pos specifier (POS=p) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

size

Is a character count specifier (SIZE=i-var). It can only be specified for nonadvancing READ statements.

iostat

Is the name of a variable to contain the completion status of the I/O operation. Optionally prefaced by IOSTAT=.

err, end, eor

Are branch specifiers if an error (ERR=label), end-of-file (END=label), or end-of-record (EOR=label) condition occurs. EOR can only be specified for nonadvancing READ statements.

io-list

Is an I/O list: the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list.
If an item in `io-list` is an expression that calls a function, that
function must not execute an I/O statement or the EOF intrinsic
function on the same external unit as `eunit`.
If I/O is to or from a formatted device, `io-list` cannot contain
derived-type variables, but it can contain components of derived
types. If I/O is to a binary or unformatted device, `io-list` can
contain either derived type components or a derived type variable.

- **form**
  Is the nonkeyword form of a format specifier (no FMT=).
- *****
  Is the format specifier indicating list-directed formatting. (It can
  also be specified as FMT=*.)
- **nml-group**
  Is the namelist group specification for namelist I/O. Optionally
  prefaced by NML=. NML= is required if `nml-group` is not the
  second I/O specifier. For more information, see Namelist Specifier.
- **nml**
  Is the nonkeyword form of a namelist specifier (no NML=)
  indicating namelist I/O.
- **rec**
  Is the cell number of a record to be accessed directly. Optionally
  prefaced by REC=.
- **iunit**
  Is an internal unit specifier, optionally prefaced by UNIT=.
  UNIT= is required if `iunit` is not the first specifier in the list. It must be
  a character variable. It must not be an array section with a vector
  subscript.

---

**CAUTION.** The READ statement can disrupt the results of certain graphics text functions
(such as SETTEXTWINDOW) that alter the location of the cursor. You can avoid the
problem by getting keyboard input with the GETCHAR function and echoing the
keystrokes to the screen using OUTTEXT. Alternatively, you can use SETTEXTPOSITION
to control cursor location.
Example

DIMENSION ia(10,20)

! Read in the bounds for the array.
! Then read in the array in nested implied-DO lists
! with input format of 8 columns of width 5 each.
READ (6, 990) il, jl, ((ia(i,j), j = 1, jl), i =1, il)
990 FORMAT (2I5, /, (8I5))
! Internal read gives a variable string-represented numbers
CHARACTER*12 str
str = '123456'
READ (str,'(i6)') i
! List-directed read uses no specified format
REAL x, y
INTEGER i, j
READ (*,*), x, y, i, j

• I/O Formatting

REAL Statement

Statement: Specifies the REAL data type.

Syntax

REAL
REAL([KIND=] n)
REAL* n
DOUBLE PRECISION

\(n\)

Is an initialization expression that evaluates to kind 4, 8 or 16.

**Description**

If a kind parameter is specified, the real constant has the kind specified. If a kind parameter is not specified, the kind is default real.

Default real is affected by compiler options specifying real size and by the REAL directive.

The default KIND for DOUBLE PRECISION is affected by compiler option double-size. If this compiler option is not specified, default DOUBLE PRECISION is REAL(8).

No kind parameter is permitted for data declared with type DOUBLE PRECISION.

REAL(4) and REAL*4 (single precision) are the same data type. REAL(8), REAL*8, and DOUBLE PRECISION are the same data type.

**Example**

Entity-oriented examples are:

```fortran
MODULE DATDECLARE
  REAL (8), OPTIONAL :: testval=50.d0
  REAL, SAVE :: a(10), b(20,30)
  REAL, PARAMETER :: x = 100.
ENDMODULE DATDECLARE
```

Attribute-oriented examples are:

```fortran
MODULE DATDECLARE
  REAL (8) testval=50.d0
  REAL x, a(10), b(20,30)
  OPTIONAL testval
  SAVE a, b
  PARAMETER (x = 100.)
ENDMODULE DATDECLARE
```

**See Also**

- Q to R
• DOUBLE PRECISION
• REAL directive
• Real Data Types
• General Rules for Real Constants
• REAL(4) Constants
• REAL(8) or DOUBLE PRECISION Constants
• Real and Complex Editing
• Model for Real Data

REAL Directive
General Compiler Directive: Specifies the default real kind.

Syntax

c DEC$ REAL: { 4 | 8 | 16 }

c Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

The REAL directive selects a size of 4 (KIND=4), 8 (KIND=8), or 16 (KIND=16) bytes for default real numbers. When the directive is in effect, all default real and complex variables are of the kind specified in the directive. Only numbers specified or implied as REAL without KIND are affected.

The REAL directive can appear only at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. REAL cannot appear between program units, or at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.
Example

REAL r ! a 4-byte REAL
WRITE(*,*) KIND(r)
CALL REAL8( )
WRITE(*,*) KIND(r) ! still a 4-byte REAL
! not affected by setting in subroutine
END

SUBROUTINE REAL8( )
!DEC$ REAL:8
REAL s ! an 8-byte REAL
WRITE(*,*) KIND(s)
END SUBROUTINE

See Also

- Q to R

REAL Function

**Elemental Intrinsic Function (Generic):**

*Converts a value to real type.*

**Syntax**

result = REAL (a[,kind])

- `a` (Input) Must be of type integer, real, or complex.
- `kind` (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is real. If `kind` is present, the kind parameter is that specified by `kind`; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.
Functions that cause conversion of one data type to another type have the same affect as the implied conversion in assignment statements.

If \( a \) is integer or real, the result is equal to an approximation of \( a \). If \( a \) is complex, the result is equal to an approximation of the real part of \( a \).

<table>
<thead>
<tr>
<th>Specific Name (^1)</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>FLOATI</td>
<td>INTEGER(1)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>FLOAT</td>
<td>INTEGER(2)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>REAL</td>
<td>INTEGER(4)</td>

<td>REAL(4)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td></td>
<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

\(^1\) These specific functions cannot be passed as actual arguments.

\(^2\) The setting of compiler options specifying real size can affect FLOAT, REAL, and SNGL.

\(^3\) Or FLOATJ. For compatibility with older versions of Fortran, FLOAT is generic, allowing any kind of INTEGER argument, and returning a default real result.

\(^4\) For compatibility with older versions of Fortran, SNGL is generic, allowing any kind of REAL argument, and returning a default real result.

**Example**

REAL (-4) has the value -4.0.

REAL (Y) has the same kind parameter and value as the real part of complex variable Y.
See Also

- DFLOAT
- DREAL
- DBLE

RECORD

Statement: Declares a record structure as an entity with a name.

Syntax

RECORD /structure-name/record-namelist
   /structure-name/record-namelist]
   ...
   [, /structure-name/record-namelist]

structure-name Is the name of a previously declared structure.
record-namelist Is a list of one or more variable names, array names, or array specifications, separated by commas. All of the records named in this list have the same structure and are allocated separately in memory.

You can use record names in COMMON and DIMENSION statements, but not in DATA or NAMELIST statements.

Records initially have undefined values unless you have defined their values in structure declarations.

STRUCTURE and RECORD constructs have been replaced by derived types, which should be used in writing new code. See Derived Data Types.
Example

STRUCTURE /address/ 
  LOGICAL*2 house_or_apt 
  INTEGER*2 apt 
  INTEGER*2 housenumber 
  CHARACTER*30 street 
  CHARACTER*20 city 
  CHARACTER*20 state 
  INTEGER*4 zip 
END STRUCTURE 

RECORD /address/ mailing_addr(20), shipping_addr(20)

RECTANGLE, RECTANGLE_W (W*32, W*64)

Graphics Functions: Draw a rectangle using the current graphics color, logical write mode, and line style.

Module
USE IFQWIN

Syntax
result = RECTANGLE (control, x1, y1, x2, y2)
result = RECTANGLE_W (control, wx1, wy1, wx2, wy2)
control (Input) INTEGER(2). Fill flag. One of the following symbolic constants (defined in IFQWIN.F90):

- $GFILLINTERIOR - Draws a solid figure using the current color and fill mask.
- $GBORDER - Draws the border of a rectangle using the current color and line style.

x1, y1 (Input) INTEGER(2). Viewport coordinates for upper-left corner of rectangle.

x2, y2 (Input) INTEGER(2). Viewport coordinates for lower-right corner of rectangle.

wx1, wy1 (Input) REAL(8). Window coordinates for upper-left corner of rectangle.

wx2, wy2 (Input) REAL(8). Window coordinates for lower-right corner of rectangle.

**Results**

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0.

The RECTANGLE function uses the viewport-coordinate system. The viewport coordinates (x1, y1) and (x2, y2) are the diagonally opposed corners of the rectangle.

The RECTANGLE_W function uses the window-coordinate system. The window coordinates (wx1, wy1) and (wx2, wy2) are the diagonally opposed corners of the rectangle.

SETCOLORRGB sets the current graphics color. SETFILLMASK sets the current fill mask. By default, filled graphic shapes are filled solid with the current color.

If you fill the rectangle using FLOODFILLRGB, the rectangle must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

**NOTE.** The RECTANGLE routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the Rectangle routine by including the IFWIN module, you need to specify the routine name as MSFWIN$Rectangle. For more information, see *Building Applications*: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines.
Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example

This program draws the rectangle shown below.

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
dummy = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
END

RECURSIVE

Keyword: Specifies that a subroutine or function can call itself directly or indirectly. Recursion is permitted if the keyword is specified in a FUNCTION or SUBROUTINE statement, or if RECURSIVE is specified as a compiler option or in an OPTIONS statement.

Description

If a function is directly recursive and array valued, the keywords RECURSIVE and RESULT must both be specified in the FUNCTION statement.

The procedure interface is explicit within the subprogram in the following cases:

- When RECURSIVE is specified for a subroutine
- When RECURSIVE and RESULT are specified for a function

The keyword RECURSIVE must be specified if any of the following applies (directly or indirectly):

- The subprogram invokes itself.
- The subprogram invokes a subprogram defined by an ENTRY statement in the same subprogram.
- An ENTRY procedure in the same subprogram invokes one of the following:
  - Itself
  - Another ENTRY procedure in the same subprogram
  - The subprogram defined by the FUNCTION or SUBROUTINE statement
Example

```fortran
! RECURS.F90
!
i = 0
CALL Inc (i)
END
RECURSIVE SUBROUTINE Inc (i)
i = i + 1
CALL Out (i)
IF (i.LT.20) CALL Inc (i)    ! This also works in OUT
END SUBROUTINE Inc
SUBROUTINE Out (i)
WRITE (*,*) i
END SUBROUTINE Out
```

**REDUCTION**

*Parallel Directive Clause:* Performs a reduction operation on the specified variables.

**Syntax**

```
REDUCTION (operator| intrinsic: list)
```

- **operator**
  - Is one of the following: +, *, -, .AND., .OR., .EQV., or .NEQV.
- **intrinsic**
  - Is one of the following: MAX, MIN, IAND, IOR, or Ieor.
Variables that appear in a REDUCTION clause must be SHARED in the enclosing context. A private copy of each variable in list is created for each thread as if the PRIVATE clause had been used. The private copy is initialized according to the operator (see the table below).

At the end of the REDUCTION, the shared variable is updated to reflect the result of combining the original value of the shared reduction variable with the final value of each of the private copies using the operator specified. The reduction operators are all associative (except for subtraction), and the compiler can freely reassociate the computation of the final value; the partial results of a subtraction reduction are added to form the final value.

The value of the shared variable becomes undefined when the first thread reaches the clause containing the reduction, and it remains undefined until the reduction computation is complete. Normally, the computation is complete at the end of the REDUCTION construct.

However, if the REDUCTION clause is used in a construct to which NOWAIT is also applied, the shared variable remains undefined until a barrier synchronization has been performed. This ensures that all the threads complete the REDUCTION clause.

The REDUCTION clause must be used in a region or worksharing construct where the reduction variable is used only in a reduction statement having one of the following forms:

- \( x = x \) operator expr
- \( x = expr \) operator \( x \) (except for subtraction)
- \( x = \) intrinsic \( (x, expr) \)
- \( x = \) intrinsic \( (expr, x) \)

Some reductions can be expressed in other forms. For instance, a MAX reduction can be expressed as follows:

\[
\text{IF } (x \lt\!\lt expr) x = expr
\]

Alternatively, the reduction might be hidden inside a subroutine call. Be careful that the operator you specify in the REDUCTION clause matches the reduction operation.

The following table lists the operators and intrinsics and their initialization values. The actual initialization value will be consistent with the data type of the reduction variable.
Table 899: Initialization Values for REDUCTION Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Initialization Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>0</td>
</tr>
<tr>
<td>*</td>
<td>1</td>
</tr>
<tr>
<td>-</td>
<td>0</td>
</tr>
<tr>
<td>.AND.</td>
<td>.TRUE.</td>
</tr>
<tr>
<td>.OR.</td>
<td>.FALSE.</td>
</tr>
<tr>
<td>.EQV.</td>
<td>.TRUE.</td>
</tr>
<tr>
<td>.NEQV.</td>
<td>.FALSE.</td>
</tr>
</tbody>
</table>

Table 900: Initialization Values for REDUCTION Intrinsics

<table>
<thead>
<tr>
<th>Intrinsic</th>
<th>Initialization Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAX</td>
<td>Smallest representable number</td>
</tr>
<tr>
<td>MIN</td>
<td>Largest representable number</td>
</tr>
<tr>
<td>IAND</td>
<td>All bits on</td>
</tr>
<tr>
<td>IOR</td>
<td>0</td>
</tr>
<tr>
<td>IEOR</td>
<td>0</td>
</tr>
</tbody>
</table>

If a directive allows reduction clauses, the number you can specify is not limited. However, each variable name can appear in only one of the clauses.

%REF

**Built-in Function:** Changes the form of an actual argument. Passes the argument by reference. In Intel® Fortran, passing by reference is the default.

**Syntax**

%REF (a)

(a) (Input) An expression, record name, procedure name, array, character array section, or array element.

You must specify %REF in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following table lists the Intel Fortran defaults for argument passing, and the allowed uses of %REF:

<table>
<thead>
<tr>
<th>Actual Argument Data Type</th>

<td>Yes</td>
</tr>
</tbody>
</table>

\(^1\)A character argument is passed by address and hidden length.

\(^2\)In Intel Fortran record structures

The %REF and %VAL functions override related cDEC$ ATTRIBUTE settings.

**Example**

```fortran
CHARACTER(LEN=10) A, B
CALL SUB(A, %REF(B))
```

Variable A is passed by address and hidden length. Variable B is passed by reference.

Note that on Windows systems, compiler option iface determines how the character argument for variable B is passed.

- CALL
- %VAL
QuickWin Function: Registers the application-supplied callback routine to be called when a specified mouse event occurs in a specified window.

Module
USE IFQWIN

Syntax
result = REGISTERMOUSEEVENT (unit, mouseevents, callbackroutine)

unit (Input) INTEGER(4). Unit number of the window whose callback routine on mouse events is to be registered.

mouseevents (Input) INTEGER(4). One or more mouse events to be handled by the callback routine to be registered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:

- MOUSE$LBUTTONDOWN - Left mouse button down
- MOUSE$LBUTTONUP - Left mouse button up
- MOUSE$LBUTTONDBLCLK - Left mouse button double-click
- MOUSE$RBUTTONDOWN - Right mouse button down
- MOUSE$RBUTTONUP - Right mouse button up
- MOUSE$RBUTTONDBLCLK - Right mouse button double-click
- MOUSE$MOVE - Mouse moved

callbackroutine (Input) Routine to be called on the specified mouse event in the specified window. It must be declared EXTERNAL. For a prototype mouse callback routine, see Building Applications: Using a Mouse.

Results
The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer that can be one of the following:
• **MOUSE$BADUNIT** - The unit specified is not open, or is not associated with a QuickWin window.

• **MOUSE$BADEVENT** - The event specified is not supported.

For every **BUTTONDOWN** or **BUTTONDBLCLK** event there is an associated **BUTTONUP** event. When the user double clicks, four events happen: **BUTTONDOWN** and **BUTTONUP** for the first click, and **BUTTONDBLCLK** and **BUTTONUP** for the second click. The difference between getting **BUTTONDBLCLK** and **BUTTONDOWN** for the second click depends on whether the second click occurs in the double click interval, set in the system's **CONTROL PANEL/MOUSE**.

**Compatibility**

**QUICKWIN GRAPHICS LIB**

**Example**

The following example registers the routine **CALCULATE**, to be called when the user double-clicks the left mouse button while the mouse cursor is in the child window opened as unit 4:

```fortran
USE IFQWIN
INTEGER(4) result
OPEN (4, FILE= 'USER')
...
result = REGISTERMOUSEEVENT (4, MOUSE$LBUTTONDBLCLK, CALCULATE)
```

**See Also**

• **Q to R**
• **UNREGISTERMOUSEEVENT**
• **WAITONMOUSEEVENT**

**REMAPALLPALETTERGB, REMAPPALETTERGB (W*32, W*64)**

**Graphics Functions:** 
**REMAPALLPALETTERGB** remaps a set of Red-Green-Blue (RGB) color values to indexes recognized by the video hardware. **REMAPPALETTERGB** remaps one color index to an RGB color value.

**Module**

USE IFQWIN
Syntax

result = REMAPALLPALETTERGB (colors)
result = REMAPPALETTERGB (index, colors)

colors     (Input) INTEGER(4). Ordered array of RGB color values to be mapped in order to indexes. Must hold 0-255 elements.
index     (Input) INTEGER(4). Color index to be reassigned an RGB color.
color     (Input) INTEGER(4). RGB color value to assign to a color index.

Results

The result type is INTEGER(4). REMAPALLPALETTERGB returns 0 if successful; otherwise, -1. REMAPPALETTERGB returns the previous color assigned to the index.

The REMAPALLPALETTERGB function remaps all of the available color indexes simultaneously (up to 236; 20 indexes are reserved by the operating system). The colors argument points to an array of RGB color values. The default mapping between the first 16 indexes and color values is shown in the following table. The 16 default colors are provided with symbolic constants in IFQWIN.F90.

<table>
<thead>
<tr>
<th>Index</th>
<th>Color</th>
<th>Index</th>
<th>Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$BLACK$</td>
<td>8</td>
<td>$GRAY$</td>
</tr>
<tr>

<tr>
<td>5</td>
<td>$MAGENTA$</td>
<td>13</td>
<td>$LIGHTMAGENTA$</td>
</tr>
<tr>
<td>6</td>
<td>$BROWN$</td>
<td>14</td>
<td>$YELLOW$</td>
</tr>
<tr>
<td>7</td>
<td>$WHITE$</td>
<td>15</td>
<td>$BRIGHTWHITE$</td>
</tr>
</tbody>
</table>

The number of colors mapped can be fewer than 236 if the number of colors supported by the current video mode is fewer, but at most 236 colors can be mapped by REMAPALLPALETTERGB. Most Windows graphics drivers support a palette of 256K colors or more, of which only a few
can be mapped into the 236 palette indexes at a time. To access and use all colors on the system, bypass the palette and use direct RGB color functions such as such as SETCOLORRGB and SETPIXELSRGB.

Any RGB colors can be mapped into the 236 palette indexes. Thus, you could specify a palette with 236 shades of red. For further details on using different color procedures see Building Applications: Adding Color Overview.

In each RGB color value, each of the three colors, red, green and blue, is represented by an eight-bit value (2 hex digits). In the values you specify with REMAPALLPALETTERGB or REMAPPALETTERGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
Bit 31 (MSB)  24  23  16  15  8  7  0
RGB 0 0 0 0 0 0 0 B B B B B B G G G G G G G R R R R R R R
```

Larger numbers correspond to stronger color intensity with binary 11111111 (hex FF) the maximum for each of the three components. For example, Z'008080' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

```
! Build as QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) colors(3)
INTEGER(2) status
colors(1) = Z'00FFFF' ! yellow
colors(2) = Z'FFFFFF' ! bright white
colors(3) = 0 ! black
status = REMAPALLPALETTERGB(colors)
status = REMAPPALETTERGB(INT2(47), Z'45A315')
END
```

Building Applications: Using Color

Building Applications: VGA Color Palette

RENAME

Portability Function: Renames a file.

Module
USE IFPORT

Syntax
result = RENAME (from, to)

from (Input) Character*(*). Path of an existing file.
to (Input) Character*(*). The new path for the file (see Caution note below).

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code, such as:

• EACCES - The file or directory specified by to could not be created (invalid path). This error is also returned if the drive specified is not currently connected to a device.
• ENOENT - The file or path specified by from could not be found.
• EXDEV - Attempt to move a file to a different device.

CAUTION. This routine can cause data to be lost. If the file specified in to already exists, RENAME deletes the pre-existing file.

It is possible to rename a file to itself without error.
The paths can use forward (/) or backward (\) slashes as path separators and can include drive letters (if permitted by your operating system).

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

use IFPORT

integer(4) istatus
character*12 old_name, new_name
print *, "Enter file to rename: "
read *, old_name
print *, "Enter new name: "
read *, new_name
ISTATUS = RENAME (old_name, new_name)

**See Also**

- Q to R
- RENAMEFILEQQ

**RENAMEFILEQQ**

*Portability Function: Renames a file.*

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{RENAMEFILEQQ} (\text{oldname}, \text{newname})
\]

\text{oldname} \quad \text{(Input) Character*(*)}. \text{Current name of the file to be renamed.}

\text{newname} \quad \text{(Input) Character*(*)}. \text{New name of the file to be renamed.}

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
You can use RENAMEFILEQQ to move a file from one directory to another on the same drive by giving a different path in the `newname` parameter.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- ERR$ACCES - Permission denied. The file's permission setting does not allow the specified access.
- ERR$EXIST - The file already exists.
- ERR$NOENT - File or path specified by `oldname` not found.
- ERR$XDEV - Attempt to move a file to a different device.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```
USE IFFORT
USE IFCORE
INTEGER(4) len
CHARACTER(80) oldname, newname
LOGICAL(4) result
WRITE(*,'(A, \)') ' Enter old name: '
len = GETSTRQQ(oldname)
WRITE(*,'(A, \)') ' Enter new name: '
len = GETSTRQQ(newname)
result = RENAMEFILEQQ(oldname, newname)
END
```

**See Also**

- Q to R
- FINDFILEQQ
- RENAME
- GETLASTERRORQQ
REPEAT

Transformational Intrinsic Function (Generic):
Concatenates several copies of a string.

Syntax
result = REPEAT (string, ncopies)

string (Input) Must be scalar and of type character.
ncopies (Input) Must be scalar and of type integer. It must not be negative.

Results
The result is a scalar of type character and length ncopies \times LEN( string). The kind parameter is the same as string. The value of the result is the concatenation of ncopies copies of string.

Example
REPEAT ('S', 3) has the value SSS.
REPEAT ('ABC', 0) has the value of a zero-length string.
The following shows another example:
CHARACTER(6) str
str = REPEAT('HO', 3) ! returns HOHOHO

See Also
• Q to R
• SPREAD

RESHAPE

Transformational Intrinsic Function (Generic):
Constructs an array with a different shape from the argument array.

Syntax
result = RESHAPE (source, shape [, pad] [, order])

source (Input) Must be an array. It may be of any data type. It supplies the elements for the result array. Its size must be greater than or equal to PRODUCT(shape) if pad is omitted or has size zero.
**shape**
(Input) Must be an integer array of up to 7 elements, with rank one and constant size. It defines the shape of the result array. Its size must be positive; its elements must not have negative values.

**pad**
(Input; optional) Must be an array with the same type and kind parameters as `source`. It is used to fill in extra values if the result array is larger than `source`.

**order**
(Input; optional) Must be an integer array with the same shape as `shape`. Its elements must be a permutation of (1,2,...,n), where n is the size of `shape`. If `order` is omitted, it is assumed to be (1,2,...,n).

**Results**
The result is an array of shape `shape` with the same type and kind parameters as `source`. The size of the result is the product of the values of the elements of `shape`.

In the result array, the array elements of `source` are placed in the order of dimensions specified by `order`. If `order` is omitted, the array elements are placed in normal array element order.

The array elements of `source` are followed (if necessary) by the array elements of `pad` in array element order. If necessary, additional copies of `pad` follow until all the elements of the result array have values.

**NOTE.** In standard Fortran array element order, the first dimension varies fastest. For example, element order in a two-dimensional array would be (1,1), (2,1), (3,1) and so on. In a three-dimensional array, each dimension having two elements, the array element order would be (1,1,1), (2, 1, 1), (1, 2, 1), (2, 2, 1), (1, 1, 2), (2, 1, 2), (1, 2, 2), (2, 2, 2).

RESHAPE can be used to reorder a Fortran array to match C array ordering before the array is passed from a Fortran to a C procedure.

**Example**
RESHAPE (/3, 4, 5, 6, 7, 8/), (/2, 3/) has the value

\[
\begin{bmatrix}
3 & 5 & 7 \\
4 & 6 & 8
\end{bmatrix}
\]
RESHAPE ((/3, 4, 5, 6, 7, 8/), (/2, 4/), (/1, 1/), (/2, 1/)) has the value
[ 3 4 5 6 ]
[ 7 8 1 1 ].

The following shows another example:
INTEGER AR1( 2, 5)
REAL F(5,3,8)
REAL C(8,3,5)
AR1 = RESHAPE((/1,2,3,4,5,6/),(/2,5/),(/0,0/),(/2,1/))
! returns 1 2 3 4 5
! 6 0 0 0 0
!
! Change Fortran array order to C array order
C = RESHAPE(F, (/8,3,5/), ORDER = (/3, 2, 1/))
END

RESULT

Keyword: Specifies a name for a function result.

Description

Normally, a function result is returned in the function’s name, and all references to the function name are references to the function result.

However, if you use the RESULT keyword in a FUNCTION statement, you can specify a local variable name for the function result. In this case, all references to the function name are recursive calls, and the function name must not appear in specification statements.

The RESULT name must be different from the name of the function.
Example

The following shows an example of a recursive function specifying a RESULT variable:

```fortran
RECURSIVE FUNCTION FACTORIAL(P) RESULT(L)
    INTEGER, INTENT(IN) :: P
    INTEGER L
    IF (P == 1) THEN
        L = 1
    ELSE
        L = P * FACTORIAL(P - 1)
    END IF
END FUNCTION
```

The following shows another example:

```fortran
recursive function FindSame(Aindex,Last,Used) & result(FindSameResult)
    type(card) Last
    integer Aindex, i
    logical matched, used(5)
    if( Aindex > 5 ) then
        FindSameResult = .true.
        return
    endif
    . . .
```

RETURN

Statement: Transfers control from a subprogram to the calling program unit.

Syntax

RETURN [expr]

expr Is a scalar expression that is converted to an integer value if necessary. The expr is only allowed in subroutines; it indicates an alternate return. (An alternate return is an obsolescent feature in Fortran 95 and Fortran 90.)

Description

When a RETURN statement is executed in a function subprogram, control is transferred to the referencing statement in the calling program unit.

When a RETURN statement is executed in a subroutine subprogram, control is transferred to the first executable statement following the CALL statement that invoked the subroutine, or to the alternate return (if one is specified).

Example

The following shows how alternate returns can be used in a subroutine:

```fortran
CALL CHECK(A, B, *10, *20, C)
...
10 ...
20 ...
   SUBROUTINE CHECK(X, Y, *, *, C)
   ...
50   IF (X) 60, 70, 80
60   RETURN
70   RETURN 1
80   RETURN 2
END
```
The value of X determines the return, as follows:

- If $X < 0$, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the calling program.
- If $X = 0$, the first alternate return (RETURN 1) occurs and control is transferred to the statement identified with label 10.
- If $X > 0$, the second alternate return (RETURN 2) occurs and control is transferred to the statement identified with label 20.

Note that an asterisk (*) specifies the alternate return. An ampersand (&) can also specify an alternate return in a CALL statement, but not in a subroutine's dummy argument list.
The following shows another example:

```fortran
SUBROUTINE Loop
CHARACTER in
10 READ (*, '(A)') in
   IF (in .EQ. 'Y') RETURN
   GOTO 10
! RETURN implied by the following statement:
END

The following example shows alternate returns:

CALL AltRet (i, *10, *20, *30)
WRITE (*, *) 'normal return'
GOTO 40
10 WRITE (*, *) 'I = 10'
   GOTO 40
20 WRITE (*, *) 'I = 20'
   GOTO 40
30 WRITE (*, *) 'I = 30'
40 CONTINUE

END

SUBROUTINE AltRet (i, *, *, *)
   IF (i .EQ. 10) RETURN 1
   IF (i .EQ. 20) RETURN 2
   IF (i .EQ. 30) RETURN 3
END
```

In this example, RETURN 1 specifies the list’s first alternate-return label, which is a symbol for the actual argument *10 in the CALL statement. RETURN 2 specifies the second alternate-return label, and RETURN 3 specifies the third alternate-return label.

**See Also**
- Q to R
REWIND

**Statement:** Positions a sequential or direct access file at the beginning of the file (the initial point).

It takes one of the following forms:

**Syntax**

```plaintext
REWIND ([UNIT=] io-unit[, ERR= label] [, IOSTAT=i-var])
```

- **REWIND** io-unit
  - *io-unit* (Input) Is an external unit specifier.
  - *label* (Output) Is the label of the branch target statement that receives control if an error occurs.
  - *i-var* (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

**Description**

The unit number must refer to a file on disk or magnetic tape, and the file must be open for sequential, direct, or append access.

If a REWIND is done on a direct access file, the NEXTREC specifier is assigned a value of 1.

If a file is already positioned at the initial point, a REWIND statement has no effect.

If a REWIND statement is specified for a unit that is not open, it has no effect.

**Example**

The following statement repositions the file connected to I/O unit 3 to the beginning of the file:

```plaintext
REWIND 3
```

Consider the following statement:

```plaintext
REWIND (UNIT=9, IOSTAT=IOS, ERR=10)
```

This statement positions the file connected to unit 9 at the beginning of the file. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.
The following shows another example:

```
WRITE (7, '(I10)') int
REWIND (7)
READ (7, '(I10)') int
```

**See Also**
- Q to R
- OPEN
- READ
- WRITE
- Data Transfer I/O Statements
- Branch Specifiers

**REWRITE**

*Statement:* Rewrites the current record.

**Syntax**

**Formatted:**

```fortran
REWRITE (eunit, format[, iostat] [, err]) [io-list]
```

**Unformatted:**

```fortran
REWRITE (eunit[, iostat][ , err]) [io-list]
```

- **eunit**
  - Is an external unit specifier ([UNIT=]io-unit).
- **format**
  - Is a format specifier ([FMT=]format).
- **iostat**
  - Is a status specifier ([IOSTAT=i-var]).
- **err**
  - Is a branch specifier (ERR=label) if an error condition occurs.
- **io-list**
  - Is an I/O list.

**Description**

In the REWRITE statement, data (translated if formatted; untranslated if unformatted) is written to the current (existing) record in a file with direct access.

The current record is the last record accessed by a preceding, successful sequential or direct-access READ statement.
Between a READ and REWRITE statement, you should not specify any other I/O statement (except INQUIRE) on that logical unit. Execution of any other I/O statement on the logical unit destroys the current-record context and causes the current record to become undefined.

Only one record can be rewritten in a single REWRITE statement operation.

The output list (and format specification, if any) must not specify more characters for a record than the record size. (Record size is specified by RECL in an OPEN statement.)

If the number of characters specified by the I/O list (and format, if any) do not fill a record, blank characters are added to fill the record.

Example

In the following example, the current record (contained in the relative organization file connected to logical unit 3) is updated with the values represented by NAME, AGE, and BIRTH:

```plaintext
REWRITE (3, 10, ERR=99) NAME, ,AGE, BIRTH
10 FORMAT (A16, I2, A8)
```

**RGBTOINTEGER (W*32, W*64)**

**QuickWin Function:** Converts three integers specifying red, green, and blue color intensities into a four-byte RGB integer for use with RGB functions and subroutines.

**Module**

USE IFQWIN

**Syntax**

```plaintext
result = RGBTOINTEGER (red, green, blue)
```

- **red** (Input) INTEGER(4). Intensity of the red component of the RGB color value. Only the lower 8 bits of red are used.
- **green** (Input) INTEGER(4). Intensity of the green component of the RGB color value. Only the lower 8 bits of green are used.
- **blue** (Input) INTEGER(4). Intensity of the blue component of the RGB color value. Only the lower 8 bits of blue are used.

**Results**

The result type is INTEGER(4). The result is the combined RGB color value.
In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value returned with RGBTOINTEGER, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24 23</th>
<th>16 15</th>
<th>8 7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0 B B B B B B B B G G G G G G G G G G R R R R R R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

**Compatibility**

QUICKWIN GRAPHICS LIB

**Example**

```fortran
! Build as a QuickWin App.
USE IFQWIN
INTEGER r, g, b, rgb, result
INTEGER(2) status
r = Z'F0'
g = Z'F0'
b = 0
rgb = RGBTOINTEGER(r, g, b)
result = SETCOLORRGB(rgb)
status = ELLIPSE($GFILLINTERIOR, INT2(40), INT2(55), &
                   INT2(90), INT2(85))
END
```

**See Also**

- INTEGERTORGB
- SETCOLORRRGB
RINDEX

Portability Function: Locates the index of the last occurrence of a substring within a string.

Module

USE IFPORT

Syntax

result = RINDEX (string, substr)

string  (Input) Character*(*). Original string to search.
substr   (Input) Character*(*). String to search for.

Results

The result type is INTEGER(4). The result is the starting position of the final occurrence of substring in string. The result is zero if substring does not occur in string.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
character*80 mainstring
character*4 shortstr
integer(4) where
mainstring="Hello Hello Hello Hello There There There"
shortstr="Hello"
where=rindex(mainstring,shortstr)
! where is 19
See Also
• Q to R
• INDEX

**RNUM**

**Elemental Intrinsic Function (Specific):**
Converts a character string to a REAL(4) value.
This function cannot be passed as an actual argument.

**Syntax**

```
result = RNUM (i)
```

\( i \) (Input) Must be of type character.

**Results**

The result type is REAL(4). The result value is the real value represented by the character string \( i \).

**Example**

`RNUM ("821.003")` has the value 821.003 of type REAL(4).

**RRSPACING**

**Elemental Intrinsic Function (Generic):**
Returns the reciprocal of the relative spacing of model numbers near the argument value.

**Syntax**

```
result = RRSPACING (x)
```

\( x \) (Input) Must be of type real.

**Results**

The result type is the same as \( x \). The result has the value \(| x^* b^{-e} | x b^p\). Parameters \( b, e, p \) are defined in Model for Real Data.

**Example**

If -3.0 is a REAL(4) value, RRSPACING (-3.0) has the value 0.75 x 2^{24}.
The following shows another example:

```fortran
REAL(4) res4
REAL(8) res8, r2
res4 = RRSPACING(3.0) ! returns 1.258291E+07
res4 = RRSPACING(-3.0) ! returns 1.258291E+07
r2 = 487923.3
res8 = RRSPACING(r2) ! returns 8.382458680573952E+015
END
```

See Also
- Q to R
- SPACING
- Data Representation Models

**RSHIFT**

*Elemental Intrinsic Function (Generic):* Shifts the bits in an integer right by a specified number of positions. See ISHFT.

**RTC**

*Portability Function:* Returns the number of seconds elapsed since a specific Greenwich mean time.

Module

USE IFPORT

Syntax

```fortran
result = RTC( )
```

Results

The result type is REAL(8). The result is the number of seconds elapsed since 00:00:00 Greenwich mean time, January 1, 1970.
Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
real(8) s, s1, time_spent
INTEGER(4) i, j
s = RTC()
call sleep(4)
s1 = RTC()
time_spent = s1 - s
PRINT *, 'It took ',time_spent,'seconds to run.'

See Also
• Q to R
• DATE_AND_TIME
• TIME portability routine

RUNQQ

Portability Function: Executes another program and waits for it to complete.

Module

USE IFPORT

Syntax

result = RUNQQ (filename,commandline)

filename (Input) Character*(*) File name of a program to be executed.
commandline (Input) Character*(*) Command-line arguments passed to the program to be executed.
Results

The result type is INTEGER(2). If the program executed with RUNQQ terminates normally, the exit code of that program is returned to the program that launched it. If the program fails, -1 is returned.

The RUNQQ function executes a new process for the operating system using the same path, environment, and resources as the process that launched it. The launching process is suspended until execution of the launched process is complete.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT

INTEGER(2) result

result = RUNQQ('myprog', '-c -r')

END

See also the example in NARGS.

See Also

- Q to R
- NARGS
- SYSTEM
- NARGS

SAVE

**Statement and Attribute:** Causes the values and definition of objects to be retained after execution of a RETURN or END statement in a subprogram.

**Syntax**

The SAVE attribute can be specified in a type declaration statement or a SAVE statement, and takes one of the following forms:
Type Declaration Statement:

\[ \text{type},[\text{att-}ls,] \ \text{SAVE} \ [, \text{att-}ls] :: \text{object}[, \text{object}] \ldots \]

Statement:

\[ \text{SAVE} \ [[::] \text{object}[, \text{object}] \ldots] \]

- **type** is a data type specifier.
- **att-ls** is an optional list of attribute specifiers.
- **object** is the name of an object, or the name of a common block enclosed in slashes (/common-block-name/).

**Description**

In Intel® Fortran, certain variables are given the SAVE attribute, or not, by default:

- **The following variables are not** saved by default:
  - Scalar local variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL without default initialization
  - Variables that are declared AUTOMATIC
  - Local variables that are allocatable arrays
  - Derived-type variables that are data initialized by default initialization of any of their components
  - RECORD variables that are data initialized by default initialization specified in its STRUCTURE declaration

- **The following variables are saved by default:**
  - COMMON variables
  - Scalar local variables not of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL of non-recursive subprograms
  - Non-scalar local variables of non-recursive subprograms
  - Module variables
  - Data initialized by DATA statements

- Local variables that are not described in the preceding two lists are saved by default.
NOTE. Certain compiler options, such as -save and -automatic (Linux and Mac OS X) or /Qsave and /automatic (Windows), and use of OpenMP can change the defaults.

To enhance portability and avoid possible compiler warning messages, Intel recommends that you use the SAVE statement to name variables whose values you want to preserve between subprogram invocations.

When a SAVE statement does not explicitly contain a list, all allowable items in the scoping unit are saved.

A SAVE statement cannot specify the following (their values cannot be saved):

- A blank common
- An object in a common block
- A procedure
- A dummy argument
- A function result
- An automatic object
- A PARAMETER (named) constant

Even though a common block can be included in a SAVE statement, individual variables within the common block can become undefined (or redefined) in another scoping unit.

If a common block is saved in any scoping unit of a program (other than the main program), it must be saved in every scoping unit in which the common block appears.

A SAVE statement has no effect in a main program.

Example

The following example shows a type declaration statement specifying the SAVE attribute:

```fortran
SUBROUTINE TEST()
    REAL, SAVE :: X, Y
END SUBROUTINE TEST
```

The following is an example of the SAVE statement:

```fortran
SAVE A, /BLOCK_B/, C, /BLOCK_D/, E
```
The following shows another example:

```fortran
SUBROUTINE MySub
    COMMON /z/ da, in, a, idum(10)
    real(8) x, y
    ...
    SAVE x, y, /z/
    ! alternate declaration
    REAL(8), SAVE :: x, y
    SAVE /z/
```

**SAVEIMAGE, SAVEIMAGE_W (W*32, W*64)**

*Graphics Functions:* Save an image from a specified portion of the screen into a Windows bitmap file.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = SAVEIMAGE (filename, ulxcoord, ulycoord, lrxcoord, lrycoord)
result = SAVEIMAGE_W (filename, ulxcoord, ulycoord, lrxcoord, lrycoord)
```

- `filename` (Input) Character*(*) Path of the bitmap file.
ulxcoord, ulycoord  (Input) INTEGER(4). Viewport coordinates for upper-left corner of the screen image to be captured.

lrxcoord, lrycoord  (Input) INTEGER(4). Viewport coordinates for lower-right corner of the screen image to be captured.

ulwxcoord, ulwycoord  (Input) REAL(8). Window coordinates for upper-left corner of the screen image to be captured.

lrwxcoord, lrwycoord  (Input) REAL(8). Window coordinates for lower-right corner of the screen image to be captured.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The SAVEIMAGE function captures the screen image within a rectangle defined by the upper-left and lower-right screen coordinates and stores the image as a Windows bitmap file specified by filename. The image is stored with a palette containing the colors displayed on the screen.

SAVEIMAGE defines the bounding rectangle in viewport coordinates. SAVEIMAGE_W defines the bounding rectangle in window coordinates.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Building Applications: Loading and Saving Images to Files

SCALE

Elemental Intrinsic Function (Generic):
Returns the value of the exponent part (of the model for the argument) changed by a specified value.

Syntax

result = SCALE (x,i)
\( x \)  
(Input) Must be of type real.

\( i \)  
(Input) Must be of type integer.

**Results**

The result type is the same as \( x \). The result has the value \( x \times b^i \). Parameter \( b \) is defined in Model for Real Data.

**Example**

If 3.0 is a REAL(4) value, SCALE (3.0, 2) has the value 12.0 and SCALE (3.0, 3) has the value 24.0.

The following shows another example:

```fortran
REAL r
r = SCALE(5.2, 2) !returns 20.8
```

**See Also**

- S
- LSHIFT
- Data Representation Models

**SCAN**

*Elemental Intrinsic Function (Generic):* Scans a string for any character in a set of characters.

**Syntax**

\[
\text{result} = \text{SCAN} (\text{string}, \text{set}, \text{back}, \text{kind})
\]

- \( \text{string} \)  
  (Input) Must be of type character.

- \( \text{set} \)  
  (Input) Must be of type character with the same kind parameter as \( \text{string} \).

- \( \text{back} \)  
  (Input) Must be of type logical.

- \( \text{kind} \)  
  (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is integer. If \( \text{kind} \) is present, the kind parameter of the result is that specified by \( \text{kind} \); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.
If `back` is omitted (or is present with the value false) and `string` has at least one character that is in `set`, the value of the result is the position of the leftmost character of `string` that is in `set`.

If `back` is present with the value true and `string` has at least one character that is in `set`, the value of the result is the position of the rightmost character of `string` that is in `set`.

If no character of `string` is in `set` or the length of `string` or `set` is zero, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

**Example**

SCAN ('ASTRING', 'ST') has the value 2.

SCAN ('ASTRING', 'ST', BACK=.TRUE.) has the value 3.

SCAN ('ASTRING', 'CD') has the value zero.

The following shows another example:

```fortran
INTEGER i
INTEGER array(2)
i = SCAN ('FORTRAN', 'TR') ! returns 3
i = SCAN ('FORTRAN', 'TR', BACK = .TRUE.) ! returns 5
i = SCAN ('FORTRAN', 'GHA') ! returns 6
i = SCAN ('FORTRAN', 'ora') ! returns 0
array = SCAN ((/'FORTRAN','VISUALC'/),(/'A', 'A'/))
! returns (6, 5)
! Note that when using SCAN with arrays, the string
! elements must be the same length. When using string
! constants, blank pad to make strings the same length.
! For example:
array = SCAN ((/'FORTRAN','MASM '/),(/'A', 'A'/))
! returns (6, 2)
END
```
See Also
• S
  • VERIFY

SCANENV

**Portability Subroutine:** Scans the environment for the value of an environment variable.

**Module**
USE IFPORT

**Syntax**
CALL SCANENV (envname, envtext, envvalue)

- **envname**  
  (Input) Character(*) (Input) Character(*). Contains the name of an environment variable you need to find the value for.

- **envtext**  
  (Output) Character(*). Set to the full text of the environment variable if found, or to ' ' if nothing is found.

- **envvalue**  
  (Output) Character(*). Set to the value associated with the environment variable if found or to ' ' if nothing is found.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

SCROLLTEXTWINDOW (W*32, W*64)

**Graphics Subroutine:** Scrolls the contents of a text window.

**Module**
USE IFQWIN

**Syntax**
CALL SCROLLTEXTWINDOW (rows)

- **rows**  
  (Input) INTEGER(2). Number of rows to scroll.
The SCROLLTEXTWINDOW subroutine scrolls the text in a text window (previously defined by SETTEXTWINDOW). The default text window is the entire window.

The *rows* argument specifies the number of lines to scroll. A positive value for *rows* scrolls the window up (the usual direction); a negative value scrolls the window down. Specifying a number larger than the height of the current text window is equivalent to calling CLEARSCREEN ($GWINDOW). A value of 0 for *rows* has no effect.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as QuickWin or Standard Graphics app.

USE IFQWIN

INTEGER(2) row, istat
CHARACTER(18) string

TYPE (rccoord) oldpos

CALL SETTEXTWINDOW (INT2(1), INT2(0), &
                      INT2(25), INT2(80))

CALL CLEARSCREEN ($GCLEARSSCREEN )

CALL SETTEXTPOSITION (INT2(1), INT2(1), oldpos)

DO row = 1, 6
    string = 'Hello, World # '
    CALL SETTEXTPOSITION( row, INT2(1), oldpos )
    WRITE(string(15:16), '(I2)') row
    CALL OUTTEXT( string )
END DO

istat = displaycursor($GCURSORON)

WRITE(*,'(1x,A)') 'Hit ENTER'
READ (*,*) ! wait for ENTER

! Scroll window down 4 lines

CALL SCROLLTEXTWINDOW(INT2(-4) )

CALL SETTEXTPOSITION (INT2(10), INT2(18), oldpos)

WRITE(*,'(2X,A)') "Hit ENTER"
READ( *,*) ! wait for ENTER

! Scroll window up 5 lines

CALL SCROLLTEXTWINDOW( INT2(5 ) )

END

Building Applications: Text Coordinates

SCWRQQ

Portability Subroutine: Returns the floating-point processor control word.

Module

USE IFPORT

Syntax

CALL SCWRQQ (control)

control (Output) INTEGER(2). Floating-point processor control word.

SCRWQQ performs the same function as the run-time subroutine GETCONTROLFPQQ, and is provided for compatibility.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

See the example in LCWRQQ.

See Also

- S
- GETCONTROLFPQQ
SECNDS Intrinsic Procedure

*Elemental Intrinsic Function (Generic):*

Provides the system time of day, or elapsed time, as a floating-point value in seconds. SECNDS can be used as an intrinsic function or as a portability function. It is an intrinsic procedure unless you specify USE IFPORT.

**Syntax**

This function must not be passed as an actual argument. It is not a pure function, so it cannot be referenced inside a FORALL construct.

```
result = SECNDS(x)
```

- **x** (Input) Must be of type real.

**Results**

The result type is the same as `x`. The result value is the time in seconds since midnight - `x`. (The function also produces correct results for time intervals that span midnight.)

The value of SECNDS is accurate to 0.01 second, which is the resolution of the system clock.

The 24 bits of precision provide accuracy to the resolution of the system clock for about one day. However, loss of significance can occur if you attempt to compute very small elapsed times late in the day.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

**Example**

The following shows how to use SECNDS to perform elapsed-time computations:

```
C    START OF TIMED SEQUENCE
    T1 = SECNDS(0.0)
C    CODE TO BE TIMED
    ...
    DELTA = SECNDS(T1)    ! DELTA gives the elapsed time
```
See Also
- S
- DATE_AND_TIME
- RTC
- SYSTEM_CLOCK
- TIME intrinsic procedure
- SECNDS portability routine

SECNDS Portability Routine

*Portability Function:* Returns the number of seconds that have elapsed since midnight, less the value of its argument. SECNDS can be used as an intrinsic function or as a portability function. It is an intrinsic procedure unless you specify USE IFPORT.

**Module**

USE IFPORT

**Syntax**

result = SECNDS (time)

*result*  (Input) REAL(4). Number of seconds, precise to a hundredth of a second (0.01), to be subtracted.

**Results**

The result type is REAL(4). The result value is the number of seconds that have elapsed since midnight, minus *time*, with a precision of a hundredth of a second (0.01).

To start the timing clock, call SECNDS with 0.0, and save the result in a local variable. To get the elapsed time since the last call to SECNDS, pass the local variable to SECNDS on the next call.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

REAL(4) s
INTEGER(4) i, j
s = SECNDS(0.0)
DO I = 1, 100000
    J = J + 1
END DO
s = SECNDS(s)
PRINT *, 'It took ',s, 'seconds to run.'

See Also
- S
- DATE_AND_TIME
- RTC
- SYSTEM_CLOCK
- TIME portability routine
- SECNDS intrinsic procedure

SECTIONS

OpenMP® Fortran Compiler Directive: Specifies one or more blocks of code that must be divided among threads in the team. Each section is executed once by a thread in the team.

Syntax

\begin{verbatim}
c$OMP SECTIONS [clause[, clause] ... ]
[c$OMP SECTION]
    block
[c$OMP SECTION
    block]...
c$OMP END SECTIONS[NOWAIT]
\end{verbatim}
\[\begin{align*}
\text{\texttt{c}} & \quad \text{Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).} \\
\text{\texttt{clause}} & \quad \text{Is one of the following:} \\
& \quad \quad \text{\texttt{FIRSTPRIVATE}} \text{ (list)} \\
& \quad \quad \text{\texttt{LASTPRIVATE}} \text{ (list)} \\
& \quad \quad \text{\texttt{PRIVATE}} \text{ (list)} \\
& \quad \quad \text{\texttt{REDUCTION}} \text{ (operator | intrinsic : list)} \\
\text{\texttt{block}} & \quad \text{Is a structured block (section) of statements or constructs. Any constituent section must also be a structured block. You cannot branch into or out of the block.}
\end{align*}\]

Each section of code is preceded by a SECTION directive, although the directive is optional for the first section. The SECTION directives must appear within the lexical extent of the SECTIONS and END SECTIONS directive pair.

The last section ends at the END SECTIONS directive. Threads that complete execution of their SECTIONs encounter an implied barrier at the END SECTIONS directive unless NOWAIT is specified.

SECTIONS directives must be encountered by all threads in a team or by none at all.

**Example**

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```
c$OMP PARALLEL
  c$OMP SECTIONS
  c$OMP SECTION
      CALL XAXIS
  c$OMP SECTION
      CALL YAXIS
  c$OMP SECTION
      CALL ZAXIS
  c$OMP END SECTIONS
  c$OMP END PARALLEL
```
See Also

- S
- OpenMP Fortran Compiler Directives

SEED

Portability Subroutine: Changes the starting point of the pseudorandom number generator.

Module

USE IFPORT

Syntax

CALL SEED (iseed)

  iseed    (Input) INTEGER(4). Starting point for RANDOM.

SEED uses iseed to establish the starting point of the pseudorandom number generator. A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM always begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in IFPORT.F90) to the SEED routine before the first call to RANDOM.

This routine is not thread-safe.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT

REAL myrand

CALL SEED(7531)

CALL RANDOM(myrand)

See Also

- S
- RANDOM
SELECT CASE...END SELECT

**Statement:** Transfers program control to a selected block of statements according to the value of a controlling expression. **CASE.**

**Example**

```fortran
CHARACTER*1 cmdchar

Files: SELECT CASE (cmdchar)
    CASE ('0')
        WRITE (*, *) "Must retrieve one to nine files"
    CASE ('1':'9')
        CALL RetrieveNumFiles (cmdchar)
    CASE ('A', 'a')
        CALL AddEntry
    CASE ('D', 'd')
        CALL DeleteEntry
    CASE ('H', 'h')
        CALL Help
    CASE DEFAULT
        WRITE (*, *) "Command not recognized; please re-enter"

END SELECT Files
```
SELECTED_CHAR_KIND

Transformational Intrinsic Function (Generic):
Returns the value of the kind type parameter of
the character set named by the argument.

Syntax

\[
\text{result} = \text{SELECTED_CHAR_KIND}(\text{name})
\]

\(\text{name}\)  (Input) Must be scalar and of type default character. Its value
must be 'DEFAULT' or 'ASCII'.

Results

The result is a scalar of type default integer.
The result is a scalar of type default integer. The result value is 1 if NAME has the value
'DEFAULT' or 'ASCII'; otherwise, the result value is -1.

SELECTED_INT_KIND

Transformational Intrinsic Function (Generic):
Returns the value of the kind parameter of an
integer data type.

Syntax

\[
\text{result} = \text{SELECTED_INT_KIND}(r)
\]

\(r\)  (Input) Must be scalar and of type integer.

Results

The result is a scalar of type default integer. The result has a value equal to the value of the
kind parameter of the integer data type that represents all values \(n\) in the range of values \(n\)
with \(-10^r < n < 10^r\).

If no such kind type parameter is available on the processor, the result is -1. If more than one
kind type parameter meets the criteria, the value returned is the one with the smallest decimal
exponent range. For more information, see Model for Integer Data.

Example

SELECTED_INT_KIND (6) = 4
The following shows another example:

i = SELECTED_INT_KIND(8)  ! returns 4
i = SELECTED_INT_KIND(3)  ! returns 2
i = SELECTED_INT_KIND(10) ! returns 8
i = SELECTED_INT_KIND(20) ! returns -1 because 10**20
                          ! is bigger than 2**63

See Also
- SELECTED_REAL_KIND

SELECTED_REAL_KIND

Transformational Intrinsic Function (Generic):
Returns the value of the kind parameter of a real
data type.

Syntax
result = SELECTED_REAL_KIND ([p] [,r])

p       (Input; optional) Must be scalar and of type integer.
r       (Input; optional) Must be scalar and of type integer.

At least one argument must be present.

Results
If p or r is absent, the result is as if the argument was present with the value zero.

The result is a scalar of type default integer. If both arguments are absent, the result is zero.
Otherwise, the result has a value equal to a value of the kind parameter of a real data type with
decimal precision, as returned by the function PRECISION, of at least p digits and a decimal
exponent range, as returned by the function RANGE, of at least r.

If no such kind type parameter is available on the processor, the result is as follows:
-1 if the precision is not available but the range is available
-2 if the exponent range is not available but the precision is available
-3 if neither is available
-4 if real types for the precision and the range are available separately but not together

If more than one kind type parameter value meets the criteria, the value returned is the one
with the smallest decimal precision. Intel Fortran currently does not return -4 for any combination
of p and r. For more information, see Model for Real Data.

Example

SELECTED_REAL_KIND (6, 70) = 8

The following shows another example:

  i = SELECTED_REAL_KIND(r=200)  ! returns 8
  i = SELECTED_REAL_KIND(13)     ! returns 8
  i = SELECTED_REAL_KIND (100, 200)  ! returns -1
  i = SELECTED_REAL_KIND (13, 5000)  ! returns -2
  i = SELECTED_REAL_KIND (100, 5000)  ! returns -3

The following example gives a compile-time error:

  i = SELECTED_REAL_KIND ()

The following example returns a 0 at run-time to indicate that there was an error:

PROGRAM TEST
CALL F ()
CONTAINS
  SUBROUTINE F (P, R)
  INTEGER, OPTIONAL :: P, R
  PRINT *, SELECTED_REAL_KIND (P=P, R=R)  ! prints 0
  END SUBROUTINE F
END PROGRAM TEST

**SEQUENCE**

Statement: Preserves the storage order of a derived-type definition.

**Syntax**

SEQUENCE

**Description**

The SEQUENCE statement allows derived types to be used in common blocks and to be equivalenced.

The SEQUENCE statement appears only as part of derived-type definitions. It causes the components of the derived type to be stored in the same sequence they are listed in the type definition. If you do not specify SEQUENCE, the physical storage order is not necessarily the same as the order of components in the type definition.

If a derived type is a sequence derived type, then any other derived type that includes it must also be a sequence type.
Example

!DEC$ PACK:1

TYPE NUM1_SEQ
  SEQUENCE
    INTEGER(2)::int_val
    REAL(4)::real_val
    LOGICAL(2)::log_val
  END TYPE NUM1_SEQ

TYPE num2_seq
  SEQUENCE
    LOGICAL(2)::log_val
    INTEGER(2)::int_val
    REAL(4)::real_val
  END TYPE num2_seq

type (num1_seq) num1
type (num2_seq) num2
character*8 t, t1
equivalence (num1,t)
equivalence (num2,t1)
num1%int_val=2
num1%real_val=3.5
num1%log_val=.TRUE.
t1(1:2)=t(7:8)
t1(3:4)=t(1:2)
t1(5:8)=t(3:6)
print *, num2%int_val, num2%real_val, num2%log_val
end

**SETACTIVEQQ (W*32, W*64)**

*QuickWin Function: Makes a child window active, but does not give it focus.*

**Module**

USE IFQWIN

**Syntax**

```plaintext
result = SETACTIVEQQ (unit)
```

- `unit` (Input) INTEGER(4). Unit number of the child window to be made active.

**Results**

The result type is INTEGER(4). The result is 1 if successful; otherwise, 0.

When a window is made active, it receives graphics output (from ARC, LINETO and OUTGTEXT, for example) but is not brought to the foreground and does not have the focus. If a window needs to be brought to the foreground, it must be given the focus. A window is given focus with FOCUSQQ, by clicking it with the mouse, or by performing I/O other than graphics on it, unless the window was opened with IOFOCUS='FALSE.'. By default, IOFOCUS='TRUE.', except for child windows opened as unit '*'.

The window that has the focus is always on top, and all other windows have their title bars grayed out. A window can have the focus and yet not be active and not have graphics output directed to it. Graphical output is independent of focus.

If IOFOCUS='TRUE.', the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

Building Applications: Using QuickWin Overview

Building Applications: Giving a Window Focus and Setting the Active Window

**SETBKCOLOR (W*32, W*64)**

*Graphics Function:* Sets the current background color index for both text and graphics.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = SETBKCOLOR (color)
```

- **color** *(Input) INTEGER(4)*. Color index to set the background color to.

**Results**

The result type is INTEGER(4). The result is the previous background color index.

**SETBKCOLOR** changes the background color index for both text and graphics. The color index of text over the background color is set with SETTEXTCOLOR. The color index of graphics over the background color (used by drawing functions such as FLOODFILL and ELLIPSE) is set with SETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB.

Changing the background color index does not change the screen immediately. The change becomes effective when CLEARSCREEN is executed or when doing text input or output, such as with READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background color index is 0, which is associated with black unless the user remaps the palette with REMAPPALETTERGB.
NOTE. The SETBKCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the SetBkColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetBkColor. For more information, see Building Applications: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example
USE IFQWIN
INTEGER(4) i
i = SETBKCOLOR(14)

Building Applications: Setting Figure Properties
Building Applications: Using Text Colors
Building Applications: Color Mixing

SETBKCOLORRGB (W*32, W*64)
Graphics Function: Sets the current background color to the given Red-Green-Blue (RGB) value.

Module
USE IFQWIN

Syntax
result = SETBKCOLORRGB (color)
color  (Input) INTEGER(4). RGB color value to set the background color to. Range and result depend on the system's display adapter.

Results
The result type is INTEGER(4). The result is the previous background RGB color value.
In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETBKCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0 B B B B B B G G G G G G R R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

The default background color is value 0, which is black. Changing the background color value does not change the screen immediately, but becomes effective when CLEARSCREEN is executed or when doing text input or output such as READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. The RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT) is set with SETTEXTCOLORRGB. The RGB color value of graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and FLOODFILLRGB) is set with SETCOLORRGB.

SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB, and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) oldcolor
INTEGER(2) status, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
oldcolor = SETBKCOLORRGB(Z'FF0000') !blue
oldcolor = SETCOLORRGB(Z'FF') ! red
CALL CLEARSCREEN ($GCLEARSCREEN)
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END

SETCLIPRGN (W*32, W*64)

Graphics Subroutine: Limits graphics output to part of the screen.

Module
USE IFQWIN
Syntax

CALL SETCLIPRGN (x1,y1,x2,y2)

x1, y1  (Input) INTEGER(2). Physical coordinates for upper-left corner of clipping region.

x2, y2  (Input) INTEGER(2). Physical coordinates for lower-right corner of clipping region.

The SETCLIPRGN function limits the display of subsequent graphics output and font text output to that which fits within a designated area of the screen (the "clipping region"). The physical coordinates (x1, y1) and (x2, y2) are the upper-left and lower-right corners of the rectangle that defines the clipping region. The SETCLIPRGN function does not change the viewport-coordinate system; it merely masks graphics output to the screen.

SETCLIPRGN affects graphics and font text output only, such as OUTGTEXT. To mask the screen for text output using OUTTEXT, use SETTEXTWINDOW.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example
This program draws an ellipse lying partly within a clipping region, as shown below.

! Build as QuickWin or Standard Graphics ap.
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2
INTEGER(4) oldcolor
x1 = 10; y1 = 50
x2 = 170; y2 = 150
! Draw full ellipse in white
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
oldcolor = SETCOLORRGB(Z'FF0000') !blue
WRITE(*,*) "Hit enter"
READ(*,*)
CALL CLEARSCREEN($GCLEARSCREEN) ! clear screen
CALL SETCLIPRGN( INT2(0), INT2(0), &
      INT2(150), INT2(125))
! only part of ellipse inside clip region drawn now
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END

The following shows the output of this program.

*Building Applications*: Setting Graphics Coordinates

**SETCOLOR (W*32, W*64)**

*Graphics Function*: Sets the current graphics color index.

**Module**

USE IFQWIN

**Syntax**

```fortran
result = SETCOLOR (color)
```

`color` (Input) INTEGER(2). Color index to set the current graphics color to.
Results
The result type is INTEGER(2). The result is the previous color index if successful; otherwise, -1.

The SETCOLOR function sets the current graphics color index, which is used by graphics functions such as ELLIPSE. The background color index is set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.

Compatibility

**SETCONTROLFPQQ**

*Portability Subroutine: Sets the value of the floating-point processor control word.*

**Module**

USE IFPORT

**Syntax**

CALL SETCONTROLFPQQ (controlword)

*controlword* (Input) INTEGER(2). Floating-point processor control word.

The floating-point control word specifies how various exception conditions are handled by the floating-point math coprocessor, sets the floating-point precision, and specifies the floating-point rounding mechanism used.

The control word can be any of the following constants (defined in **IFPORT.F90**):

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCW$MCW_IC</td>
<td>Z’1000’</td>
<td>Infinity control mask</td>
</tr>
<tr>
<td>FPCW$AFFINE</td>
<td>Z’1000’</td>
<td>Affine infinity</td>
</tr>
<tr>
<td>FPCW$PROJECTIVE</td>
<td>Z’0000’</td>
<td>Projective infinity</td>
</tr>
<tr>
<td>FPCW$MCW_PC</td>
<td>Z’0300’</td>
<td>Precision control mask</td>
</tr>
<tr>
<td>FPCW$64</td>
<td>Z’0300’</td>
<td>64-bit precision</td>
</tr>
<tr>
<td>FPCW$53</td>
<td>Z’0200’</td>
<td>53-bit precision</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Hex value</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>FPCW$24</td>
<td>Z’0000’</td>
<td>24-bit precision</td>
</tr>
<tr>
<td>FPCW$MCW_RC</td>
<td>Z’0C00’</td>
<td>Rounding control mask</td>
</tr>
<tr>
<td>FPCW$CHOP</td>
<td>Z’0C00’</td>
<td>Truncate</td>
</tr>
<tr>
<td>FPCW$UP</td>
<td>Z’0800’</td>
<td>Round up</td>
</tr>
<tr>
<td>FPCW$DOWN</td>
<td>Z’0400’</td>
<td>Round down</td>
</tr>
<tr>
<td>FPCW$NEAR</td>
<td>Z’0000’</td>
<td>Round to nearest</td>
</tr>
<tr>
<td>FPCW$MCW_EM</td>
<td>Z’003F’</td>
<td>Exception mask</td>
</tr>
<tr>
<td>FPCW$INVALID</td>
<td>Z’0001’</td>
<td>Allow invalid numbers</td>
</tr>
<tr>
<td>FPCW$DENORMAL</td>
<td>Z’0002’</td>
<td>Allow denormals (very small numbers)</td>
</tr>
<tr>
<td>FPCW$ZERODIVIDE</td>
<td>Z’0004’</td>
<td>Allow divide by zero</td>
</tr>
<tr>
<td>FPCW$OVERFLOW</td>
<td>Z’0008’</td>
<td>Allow overflow</td>
</tr>
<tr>
<td>FPCW$UNDERFLOW</td>
<td>Z’0010’</td>
<td>Allow underflow</td>
</tr>
<tr>
<td>FPCW$INEXACT</td>
<td>Z’0020’</td>
<td>Allow inexact precision</td>
</tr>
</tbody>
</table>

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0.

Setting the floating-point precision and rounding mechanism can be useful if you are reusing old code that is sensitive to the floating-point precision standard used and you want to get the same results as on the old machine.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings. If you need to change the control word, always use SETCONTROLFPQQ to make sure that special routines handling floating-point stack exceptions and abnormal propagation work correctly.

For a full discussion of the floating-point control word, exceptions, and error handling, see *Building Applications: The Floating-Point Environment Overview.*
NOTE. The Intel® Fortran exception handler allows for software masking of invalid operations, but does not allow the math chip to mask them. If you choose to use the software masking, be aware that this can affect program performance if you compile code written for Intel Fortran with another compiler.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT

INTEGER(2) status, control, controlo

CALL GETCONTROLFPQQ(control)

WRITE (*, 9000) 'Control word: ', control

! Save old control word
controlo = control

! Clear all flags
control = control .AND. Z'0000'

! Set new control to round up
control = control .OR. FPCW$UP

CALL SETCONTROLFPQQ(control)

CALL GETCONTROLFPQQ(control)

WRITE (*, 9000) 'Control word: ', control

9000 FORMAT (1X, A, Z4)

END

SETDAT

**Portability Function:** Sets the system date. This function is only available on Windows* and Linux* systems.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{SETDAT}(\text{iyr}, \text{imon}, \text{iday})
\]

- `iyr` (Input) INTEGER(2) or INTEGER(4). Year (xxxxAD).
- `imon` (Input) INTEGER(2) or INTEGER(4). Month (1-12).
- `iday` (Input) INTEGER(2) or INTEGER(4). Day of the month (1-31).

**Results**

The result type is LOGICAL(4). The result is .TRUE. if the system date is changed; .FALSE. if no change is made.

Actual arguments of the function SETDAT can be any valid INTEGER(2) or INTEGER(4) expression.

Refer to your operating system documentation for the range of permitted dates.

**NOTE.** On Linux systems, you must have root privileges to execute this function.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

LOGICAL(4) success

success = SETDAT(INT2(1997+1), INT2(2*3), INT2(30))

END

See Also
- S
- GETDAT
- GETTIM
- SETTIM

SETENVQQ

*Portability Function:* Sets the value of an existing environment variable, or adds and sets a new environment variable.

Module

USE IFPORT

Syntax

result = SETENVQQ (varname=value)

varname=value (Input) Character*(*). String containing both the name and the value of the variable to be added or modified. Must be in the form: varname = value, where varname is the name of an environment variable and value is the value being assigned to it.

Results

The result is of type LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

Environment variables define the environment in which a program executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

SETENVQQ deletes any terminating blanks in the string. Although the equal sign (=) is an illegal character within an environment value, you can use it to terminate value so that trailing blanks are preserved. For example, the string PATH= =sets value to '".'
You can use SETENVQQ to remove an existing variable by giving a variable name followed by an equal sign with no value. For example, LIB= removes the variable LIB from the list of environment variables. If you specify a value for a variable that already exists, its value is changed. If the variable does not exist, it is created.

SETENVQQ affects only the environment that is local to the current process. You cannot use it to modify the command-level environment. When the current process terminates, the environment reverts to the level of the parent process. In most cases, this is the operating system level. However, you can pass the environment modified by SETENVQQ to any child process created by RUNQQ. These child processes get new variables and/or values added by SETENVQQ.

SETENVQQ uses the C runtime routine _putenv and GETENVQQ uses the C runtime routine getenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.

SETENVQQ and GETENVQQ will not work properly with the Windows* APIs SetEnvironmentVariable and GetEnvironmentVariable.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
LOGICAL(4) success
success = SETENVQQ("PATH=c:\mydir\tmp")
success = &
SETENVQQ("LIB=c:\mylib\bessel.lib;c:\math\difq.lib")
END

See Also

• S
• GETENVQQ
• RUNQQ
SETERRORMODEQQ

Portability Subroutine: Sets the prompt mode for critical errors that by default generate system prompts.

Module
USE IFPORT

Syntax
CALL SETERRORMODEQQ (pmode)

pmode (Input) LOGICAL(4). Flag that determines whether a prompt is displayed when a critical error occurs.

Certain I/O errors cause the system to display an error prompt. For example, attempting to write to a disk drive with the drive door open generates an "Abort, Retry, Ignore" message. When the system starts up, system error prompting is enabled by default (pmode= .TRUE.). You can also enable system error prompts by calling SETERRORMODEQQ with pmode set to ERR$HARDPROMPT (defined in IFPORT.F90).

If prompt mode is turned off, critical errors that normally cause a system prompt are silent. Errors in I/O statements such as OPEN, READ, and WRITE fail immediately instead of being interrupted with prompts. This gives you more direct control over what happens when an error occurs. For example, you can use the ERR= specifier to designate an executable statement to branch to for error handling. You can also take a different action than that requested by the system prompt, such as opening a temporary file, giving a more informative error message, or exiting.

You can turn off prompt mode by setting pmode to .FALSE. or to the constant ERR$HARDFAIL (defined in IFPORT.F90).

Note that SETERRORMODEQQ affects only errors that generate a system prompt. It does not affect other I/O errors, such as writing to a nonexistent file or attempting to open a nonexistent file with STATUS='OLD'.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**Example**

! PROGRAM 1

! DRIVE B door open
OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
! Generates a system prompt error here and waits for the user
! to respond to the prompt before continuing
100 WRITE(*,*) ' Continuing'
END

! PROGRAM 2

! DRIVE B door open
USE IFPORT
CALL SETERRORMODEQQ(.FALSE.)
OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
! Causes the statement at label 100 to execute
! without system prompt
100 WRITE(*,*) ' Drive B: not available, opening &
 & alternative drive.'
   OPEN (10, FILE = 'C:\NOFILE.DAT')
END

**SETEXITQQ**

*QuickWin Function: Sets a QuickWin application's exit behavior.*

**Module**

USE IFQWIN

**Syntax**

result = SETEXITQQ (exitmode)
exitmode (Input) INTEGER(4). Determines the program exit behavior. The following exit parameters are defined in IFQWIN.F90:

- QWIN$EXITPROMPT - Displays the following message box:
  "Program exited with exit status X. Exit Window?"
  where X is the exit status from the program.
  If Yes is entered, the application closes the window and terminates. If No is entered, the dialog box disappears and you can manipulate the windows as usual. You must then close the window manually.
- QWIN$EXITNOPERSIST - Terminates the application without displaying a message box.
- QWIN$EXITPERSIST - Leaves the application open without displaying a message box.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value. The default for both QuickWin and Standard Graphics applications is QWIN$EXITPROMPT.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as QuickWin Ap

USE IFQWIN

INTEGER(4) exmode, result

WRITE(*,'(1X,A,/)') 'Please enter the exit mode 1, 2 & or 3'

READ(*,*) exmode

SELECT CASE (exmode)
CASE (1)
  result = SETEXITQQ(QWIN$EXITPROMPT)
CASE (2)
  result = SETEXITQQ(QWIN$EXITNOPERSIST)
CASE (3)
  result = SETEXITQQ(QWIN$EXITPERSIST)
CASE DEFAULT
  WRITE(*,*) 'Invalid option - checking for bad & return'
  IF(SETEXITQQ(exmode).NE.-1) THEN
    WRITE(*,*) 'Error not returned'
  ELSE
    WRITE(*,*) 'Error code returned'
  ENDIF
END SELECT
END

Building Applications: Using QuickWin Overview
**SET_EXPONENT**

**Elemental Intrinsic Function (Generic):**
Returns the value of the exponent part (of the model for the argument) set to a specified value.

**Syntax**

\[
\text{result} = \text{SET_EXPONENT} (x, i)
\]

- \(x\) (Input) Must be of type real.
- \(i\) (Input) Must be of type integer.

**Results**
The result type is the same as \(x\). The result has the value \(x \times b^{i-e}\). Parameters \(b\) and \(e\) are defined in Model for Real Data. If \(x\) has the value zero, the result is zero.

**Example**
If 3.0 is a REAL(4) value, SET_EXPONENT(3.0, 1) has the value 1.5.

**See Also**
- S
- EXPONENT
- Data Representation Models

**SETFILEACCESSQQ**

**Portability Function:** Sets the file access mode for a specified file.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{SETFILEACCESSQQ} (\text{filename, access})
\]

- \(\text{filename}\) (Input) Character*(*). Name of a file to set access for.
access (Input) INTEGER(4). Constant that sets the access. Can be any combination of the following flags, combined by an inclusive OR (such as IOR or OR):

- FILE$ARCHIVE - Marked as having been copied to a backup device.
- FILE$HIDDEN - Hidden. The file does not appear in the directory list that you can request from the command console.
- FILE$NORMAL - No special attributes (default).
- FILE$READONLY - Write-protected. You can read the file, but you cannot make changes to it.
- FILE$SYSTEM - Used by the operating system.

The flags are defined in module IFPORT.F90.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
To set the access value for a file, add the constants representing the appropriate access.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
INTEGER(4) permit
LOGICAL(4) result
permit = 0 ! clear permit
permit = IOR(FILE$READONLY, FILE$HIDDEN)
result = SETFILEACCESSQQ ('formula.f90', permit)
END

See Also
• S
• GETFILEINFOQQ
SETFILETIMEQQ

Portability Function: Sets the modification time for a specified file.

Module
USE IFPORT

Syntax
result = SETFILETIMEQQ (filename, timedate)

filename (Input) Character*(*). Name of a file.
timedate (Input) INTEGER(4). Time and date information, as packed by PACKTIMEQQ.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The modification time is the time the file was last modified and is useful for keeping track of different versions of the file. The process that calls SETFILETIMEQQ must have write access to the file; otherwise, the time cannot be changed. If you set timedate to FILE$CURTIME (defined in IFPORT.F90), SETFILETIMEQQ sets the modification time to the current system time.

If the function fails, call GETLASTERRORQQ to determine the reason. It can be one of the following:

- ERR$ACCES - Permission denied. The file's (or directory's) permission setting does not allow the specified access.
- ERR$INVAL - Invalid argument; the timedate argument is invalid.
- ERR$MFILE - Too many open files (the file must be opened to change its modification time).
- ERR$NOENT - File or path not found.
- ERR$NOMEM - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

INTEGER(2) day, month, year
INTEGER(2) hour, minute, second, hund
INTEGER(4) timedate
LOGICAL(4) result
CALL GETDAT(year, month, day)
CALL GETTIM(hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, &
    hour, minute, second)
result = SETFILETIMEQQ('myfile.dat', timedate)
END

See Also
- S
- PACKTIMEQQ
- UNPACKTIMEQQ
- GETLASTERRORQQ

SETFILLMASK (W*32, W*64)

*Graphics Subroutine: Sets the current fill mask to a new pattern.*

Module

USE IFQWIN

Syntax

CALL SETFILLMASK (mask)

*mask* (Input) INTEGER(1). One-dimensional array of length 8.

There are 8 bytes in *mask*, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of *mask* becomes the top 8 bits of the pattern, and the eighth element (byte) of *mask* becomes the bottom 8 bits.
During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of zero are set to the current background color. The current graphics color is set with SETCOLORRGB or SETCOLOR. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with SETFILLMASK), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (FLOODFILLRGB, PIE, ELLIPSE, POLYGON, and RECTANGLE).

To change the current fill mask, determine the array of bytes that corresponds to the desired bit pattern and set the pattern with SETFILLMASK, as in the following example.

<table>
<thead>
<tr>
<th>Bit pattern</th>
<th>Value in mask</th>
</tr>
</thead>
<tbody>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(1) = Z'93'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(2) = Z'C9'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(3) = Z'64'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(4) = Z'B2'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(5) = Z'59'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(6) = Z'2C'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(7) = Z'96'</td>
</tr>
<tr>
<td>● ● ● ● ● ● ● ●</td>
<td>mask(8) = Z'4B'</td>
</tr>
</tbody>
</table>

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

This program draws six rectangles, each with a different fill mask, as shown below.

USE IFQWIN

INTEGER(1), TARGET :: style1(8) &
/Z'18',Z'18',Z'18',Z'18',Z'18',Z'18',Z'18',Z'18'/

INTEGER(1), TARGET :: style2(8) &
/Z'08',Z'08',Z'08',Z'08',Z'08',Z'08',Z'08',Z'08'/

INTEGER(1), TARGET :: style3(8) &
/Z'18',Z'00',Z'18',Z'18',Z'18',Z'00',Z'18',Z'18'/

INTEGER(1), TARGET :: style4(8) &
/Z'00',Z'08',Z'00',Z'08',Z'08',Z'08',Z'08',Z'08'/

INTEGER(1), TARGET :: style5(8) &
/Z'18',Z'18',Z'00',Z'18',Z'18',Z'00',Z'18',Z'18'/

INTEGER(1), TARGET :: style6(8) &
/Z'08',Z'00',Z'08',Z'00',Z'08',Z'08',Z'00',Z'08' /

INTEGER(1) oldstyle(8) ! Placeholder for old style

INTEGER loop

INTEGER(1), POINTER :: ptr(:)

CALL GETFILLMASK( oldstyle )

! Make 6 rectangles, each with a different fill

DO loop = 1, 6
  SELECT CASE (loop)
    CASE (1)
      ptr => style1
    CASE (2)
      ptr => style2
    CASE (3)
...
ptr => style3
CASE (4)
  ptr => style4
CASE (5)
  ptr => style5
CASE (6)
  ptr => style6
END SELECT
CALL SETFILLMASK(ptr)
status = RECTANGLE($GFILLINTERIOR,INT2(loop*40+5), &
                     INT2(90),INT2((loop+1)*40), INT2(110))
END DO
CALL SETFILLMASK(oldstyle) ! Restore old style
READ (*,*) ! Wait for ENTER to be pressed
END

The following shows the output of this program.

![Typical fill masks for rectangle](image)

SETFONT (W*32, W*64)

**Graphics Function:** Finds a single font that matches a specified set of characteristics and makes it the current font used by the OUTGTEXT function.

**Module**

USE IFQWIN

**Syntax**

```
result = SETFONT (options)

options (Input) Character*(*). String describing font characteristics (see below for details).
```

**Results**

The result type is INTEGER(2). The result is the index number \( x \) as used in the \( nx \) option of the font if successful; otherwise, -1.

The SETFONT function searches the list of available fonts for a font matching the characteristics specified in \( \text{options} \). If a font matching the characteristics is found, it becomes the current font. The current font is used in all subsequent calls to the OUTGTEXT function. There can be only one current font.

The \( \text{options} \) argument consists of letter codes, as follows, that describe the desired font. The argument is neither case sensitive nor position sensitive.

- **t 'fontname'**
  - Name of the desired typeface. It can be any installed font.
- **h y**
  - Character height, where \( y \) is the number of pixels.
- **w x**
  - Select character width, where \( x \) is the number of pixels.
Select only a fixed-space font (do not use with the p characteristic).

Select only a proportional-space font (do not use with the f characteristic).

Select only a vector-mapped font (do not use with the r characteristic). Roman, Modern, and Script are examples of vector-mapped fonts, also called plotter fonts. True Type fonts (for example, Arial, Symbol, and Times New Roman) are not vector-mapped.

Select only a raster-mapped (bitmapped) font (do not use with the v characteristic). Courier, Helvetica, and Palatino are examples of raster-mapped fonts, also called screen fonts. True Type fonts are not raster-mapped.

Select the bold text format. This parameter is ignored if the font does not allow the bold format.

Select the underline text format. This parameter is ignored if the font does not allow underlining.

Select the italic text format. This parameter is ignored if the font does not allow italics.

Select the font that best fits the other parameters specified.

Select font number x, where x is less than or equal to the value returned by the INITIALIZEFONTS function.

You can specify as many options as you want, except with nx, which should be used alone. If you specify options that are mutually exclusive (such as the pairs f/p or r/v), the SETFONT function ignores them. There is no error detection for incompatible parameters used with nx.
If the \texttt{b} option is specified and at least one font is initialized, \texttt{SETFONT} sets a font and returns 0 to indicate success.

In selecting a font, the \texttt{SETFONT} routine uses the following criteria, rated from highest precedence to lowest:

1. Pixel height
2. Typeface
3. Pixel width
4. Fixed or proportional font

You can also specify a pixel width and height for fonts. If you choose a nonexistent value for either and specify the \texttt{b} option, \texttt{SETFONT} chooses the closest match.

A smaller font size has precedence over a larger size. If you request Arial 12 with best fit, and only Arial 10 and Arial 14 are available, \texttt{SETFONT} selects Arial 10.

If you choose a nonexistent value for pixel height and width, the \texttt{SETFONT} function applies a magnification factor to a vector-mapped font to obtain a suitable font size. This automatic magnification does not apply if you specify the \texttt{r} option (raster-mapped font), or if you request a specific typeface and do not specify the \texttt{b} option (best-fit).

If you specify the \texttt{n} parameter, \texttt{SETFONT} ignores any other specified options and supplies only the font number corresponding to \texttt{n}.

If a height is given, but not a width, \texttt{SETFONT} computes the a width to preserve the correct font proportions.

If a width is given, but not a height, \texttt{SETFONT} uses a default height, which may vary from font type to font type. This may lead to characters that appear distorted, particularly when a very wide width is specified. This behavior is the same as that of the Windows API \texttt{CreateFontIndirect}. A sample program is provided below showing you how to calculate the correct height for a given width.

The font functions affect only \texttt{OUTGTEXT} and the current graphics position; no other Fortran Graphics Library output functions are affected by font usage.

For each window you open, you must call \texttt{INITIALIZEFONTS} before calling \texttt{SETFONT}. \texttt{INITIALIZEFONTS} needs to be executed after each new child window is opened in order for a subsequent \texttt{SETFONT} call to be successful.

\textbf{Compatibility}

\texttt{STANDARD GRAPHICS QUICKWIN GRAPHICS LIB}
Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
! Set typeface to Arial, character height to 18,
! character width to 10, and italic
fontnum = SETFONT ('t''Arial''h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Demo text')
END
Another example follows:

! The following program shows you how to compute
! an appropriate font height for a given font width
!
! Build as a Graphics ap.

USE IFQWIN

INTEGER(2) fontnum, numfonts

TYPE (xycoord) pos

TYPE (rccoord) rcc

TYPE (FONTINFO) info

CHARACTER*11 str, str1

CHARACTER*22 str2

real rh

integer h, inw

str = "t'Arial'bih"

str1 = " "

numfonts = INITIALIZEFONTS ( )

! Default both height and width. This seems to work
! properly. From this setting get the ratio between
! height and width.

fontnum = SETFONT ("t'Arial'")

return = GETFONTINFO(info)

rh = real(info%pixheight)/real(info%avgwidth)

! Now calculate the height for a width of 40

write(*,*) 'Input desired width:'

read(*,*) inw

h = int(inw*rh)

write(str1,'(I3.3)') h

str2 = str//str1
print *,str2
fontnum = SETFONT (str2)
CALL MOVETO (INT2(10), INT2(50), pos)
CALL OUTGTEXT('ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz1234567890123456789012345')
CALL MOVETO (INT2(10), INT2(50+10+h), pos)
CALL OUTGTEXT('1234567890123456789012345')
ireturn = GETFONTINFO(info)
call settextposition(4,1, rcc)
print *, info%avgwidth, info%pixheight
END

See Also

• GRSTATUS
• OUTGTEXT
• INITIALIZEFONTS
• SETGTEXTROTATION

Building Applications: Setting the Font and Displaying Text

Building Applications: SHOWFONT.F90 Example

SETGTEXTROTATION (W*32, W*64)

Graphics Subroutine: Sets the orientation angle of the font text output in degrees. The current orientation is used in calls to OUTGTEXT.

Module
USE IFQWIN

Syntax
CALL SETGTEXTROTATION (degree-tenths)
**degree-tenths**  (Input) INTEGER(4). Angle of orientation, in tenths of degrees, of the font text output.

The orientation of the font text output is set in tenths of degrees. Horizontal is 0°, and angles increase counterclockwise so that 900 (90°) is straight up, 1800 (180°) is upside down and left, 2700 (270°) is straight down, and so forth. If the user specifies a value greater than 3600 (360°), the subroutine takes a value equal to:

\[ \text{MODULO (user-specified tenths of degrees, 3600)} \]

Although SETGTEXTROTATION accepts arguments in tenths of degrees, only increments of one full degree differ visually from each other on the screen.

Bitmap fonts cannot be rotated; TruType fonts should be used instead.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

```
! Build as a Graphics app.
USE IFQWIN
INTEGER(2) fontnum, numfonts
INTEGER(4) oldcolor, deg
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
fontnum = SETFONT ('t''Arial''h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Straight text')
deg = -1370
CALL SETGTEXTROTATION(deg)
oldcolor = SETCOLORRGB(Z'008080')
CALL OUTGTEXT('Slanted text')
END
```

**See Also**

• S
**SETLINESTYLE (W*32, W*64)**

*Graphics Subroutine:* Sets the current line style to a new line style.

**Module**

USE IFQWIN

**Syntax**

CALL SETLINESTYLE (mask)

*mask* (Input) INTEGER(2). Desired Quickwin line-style mask. (See the table below.)

The mask is mapped to the style that most closely equivalence the percentage of the bits in the mask that are set. The style produces lines that cover a certain percentage of the pixels in that line.

**SETLINESTYLE** sets the style used in drawing a line. You can choose from the following styles:

<table>
<thead>
<tr>
<th>QuickWin Mask</th>
<th>Internal Windows* Style</th>
<th>Selection Criteria</th>
<th>Appearance</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xFFFF</td>
<td>PS_SOLID</td>
<td>16 bits on</td>
<td></td>
</tr>
<tr>
<td>0xEEEEE</td>
<td>PS_DASH</td>
<td>11 to 15 bits on</td>
<td>-----------</td>
</tr>
<tr>
<td>0xECED</td>
<td>PS_DASHDOT</td>
<td>10 bits on</td>
<td>-.-.-.-.-.-.</td>
</tr>
<tr>
<td>0xECCE</td>
<td>PS_DASHDOTDOT</td>
<td>9 bits on</td>
<td>-.-.-.-.-.-.</td>
</tr>
<tr>
<td>0xAaaa</td>
<td>PS_DOT</td>
<td>1 to 8 bits on</td>
<td>.............</td>
</tr>
<tr>
<td>0x0000</td>
<td>PS_NULL</td>
<td>0 bits on</td>
<td></td>
</tr>
</tbody>
</table>

SETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON, and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE, or PIE.

The current graphics color is set with SETCOLORRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.
Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) status, style
TYPE (xycoord) xy
style = 2'FFFF'
CALL SETLINESTYLE(style)
CALL MOVETO(INT2(50), INT2(50), xy )
status = LINETO(INT2(300), INT2(300))
END

<td>&quot;Help Not Available for Menu Item&quot;</td>
</tr>
<tr>
<td>QWIN$MSG_TITLETEXT</td>
<td>&quot;Graphic&quot;</td>
</tr>
</tbody>
</table>

QWIN$MSG_FILEOPENDLG and QWIN$MSG_BMPSAVEDLG control the text in file choosing dialog boxes and have the following syntax:

"file description, file designation"

You can change any string produced by QuickWin by calling SETMESSAGEQQ with the appropriate id. This includes status messages displayed at the bottom of a QuickWin application, state messages (such as "Paused"), and dialog box messages. These messages can include multibyte characters. (For more information on multibyte characters, see Building Applications: Using National Language Support Routines Overview.) To change menu messages, use MODIFYMENUSTRINGQQ.
Compatibility

QUICKWIN GRAPHICS LIB

Example

USE IFQWIN
print*, "Hello"
CALL SETMESSAGEQQ('Changed exit text', QWIN$MSG_EXITQ)

Building Applications: Displaying Character-Based Text

SETMOUSECURSOR (W*32, W*64)

Quickwin Function: Sets the shape of the mouse cursor for the window in focus.

Module

USE IFQWIN
USE IFWIN

Syntax

oldcursor = SETMOUSECURSOR (newcursor)

newcursor (Input) INTEGER(4). A Windows HCURSOR value. For many predefined shapes, LoadCursor(0, shape) is a convenient way to get a legitimate value. See the list of predefined shapes below. A value of zero prevents the cursor from being displayed.

Results

The result type is INTEGER(4). This is also an HCURSOR Value. The result is the previous cursor value.
The window in focus at the time SETMOUSECURSOR is called has its cursor changed to the specified value. Once changed, the cursor retains its shape until another call to SETMOUSECURSOR.

In Standard Graphics applications, units 5 and 6 (the default screen input and output units) are always considered to be in focus.

The following predefined values for cursor shapes are available:

<table>
<thead>
<tr>
<th>Predefined Value</th>
<th>Cursor Shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDC_APPSTARTING</td>
<td>Standard arrow and small hourglass</td>
</tr>
<tr>
<td>IDC_ARROW</td>
<td>Standard arrow</td>
</tr>
<tr>
<td>IDC_CROSS</td>
<td>Crosshair</td>
</tr>
<tr>
<td>IDC_IBEAM</td>
<td>Text I-beam</td>
</tr>
<tr>
<td>IDC_ICON</td>
<td>Obsolete value</td>
</tr>
<tr>
<td>IDC_NO</td>
<td>Slashed circle</td>
</tr>
<tr>
<td>IDC_SIZE</td>
<td>Obsolete value; use IDC_SIZEALL</td>
</tr>
<tr>
<td>IDC_SIZEALL</td>
<td>Four-pointed arrow</td>
</tr>
<tr>
<td>IDC_SIZENESW</td>
<td>Double-pointed arrow pointing northeast and southwest</td>
</tr>
<tr>
<td>IDC_SIZENS</td>
<td>Double-pointed arrow pointing north and south</td>
</tr>
<tr>
<td>IDC_SIZENWSE</td>
<td>Double-pointed arrow pointing northwest and southeast</td>
</tr>
<tr>
<td>IDC_SIZEWE</td>
<td>Double-pointed arrow pointing west and east</td>
</tr>
<tr>
<td>IDC_UPARROW</td>
<td>Vertical arrow</td>
</tr>
<tr>
<td>IDC_WAIT</td>
<td>Hour glass</td>
</tr>
</tbody>
</table>

A LoadCursor must be done on these values before they can be used by SETMOUSECURSOR.
Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example

! Build as Standard Graphics or QuickWin

use ifqwin
use ifwin

integer*4 cursor, oldcursor
write(6,*) 'The cursor will now be changed to an hour glass shape'
write(6,*) 'Hit <return> to see the next change'
cursor = LoadCursor(0, IDC_WAIT)
oldcursor = SetMouseCursor(cursor)
read(5,*)
write(6,*) 'The cursor will now be changed to a cross-hair shape'
write(6,*) 'Hit <return> to see the next change'
cursor = LoadCursor(0, IDC_CROSS)
oldcursor = SetMouseCursor(cursor)
read(5,*)
write(6,*) 'The cursor will now be turned off'
write(6,*) 'Hit <return> to see the next change'
oldcursor = SetMouseCursor(0)
read(5,*)
write(6,*) 'The cursor will now be turned on'
write(6,*) 'Hit <return> to see the next change'
oldcursor = SetMouseCursor(oldcursor)
read(5,*)

stop
end
SETPIXEL, SETPIXEL_W (W*32, W*64)

Graphics Functions: Set a pixel at a specified location to the current graphics color index.

Module
USE IFQWIN

Syntax
result = SETPIXEL (x, y)
result = SETPIXEL_W (wx, wy)

x, y  (Input) INTEGER(2). Viewport coordinates for target pixel.
w x, wy  (Input) REAL(8). Window coordinates for target pixel.

Results
The result type is INTEGER(2). The result is the previous color index of the target pixel if successful; otherwise, -1 (for example, if the pixel lies outside the clipping region).

SETPIXEL sets the specified pixel to the current graphics color index. The current graphics color index is set with SETCOLOR and retrieved with GETCOLOR. The non-RGB color functions (such as SETCOLOR and SETPIXELS) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function, rather than a palette index with a non-RGB color function. SETPIXELRGB and SETPIXELRGB_W give access to the full color capacity of the system by using direct color values rather than indexes to a palette.

NOTE. The SETPIXEL routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the SetPixel routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetPixel. For more information, see Building Applications: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) status, x, y
status = SETCOLOR(INT2(2))
x = 10
! Draw pixels.
DO y = 50, 389, 3
  status = SETPIXEL( x, y )
  x = x + 2
END DO
READ (*,*) ! Wait for ENTER to be pressed
END

• GETCOLOR
• SETCOLOR

Building Applications: Using Color

SETPIXELRGB, SETPIXELRGB_W (W*32, W*64)

Graphics Functions: Set a pixel at a specified location to the specified Red-Green-Blue (RGB) color value.

Module
USE IFQWIN
Syntax

result = SETPIXELRGB (x, y, color)
result = SETPIXELRGB_W (x, y, color)

x, y      (Input) INTEGER(2). Viewport coordinates for target pixel.
wx, wy    (Input) REAL(8). Window coordinates for target pixel.

Results

The result type is INTEGER(4). The result is the previous RGB color value of the pixel.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETPIXELRGB or SETPIXELRGB_W, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

```
Bit  | 31 (MSB) | 24  | 23  | 16 | 15 | 8  | 7  | 0  |
RGB  | 0 0 0 0 0 0 0 0 | B B B B B B B B | G G G G G G G G | R R R R R R R R |
```

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

If any of the pixels are outside the clipping region, those pixels are ignored.

SETPIXELRGB (and the other RGB color selection functions such as SETPIXELSRGB, SETCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

Compatibility

- SETPIXELSRGB

Building Applications: Color Mixing
**SETPIXELS (W*32, W*64)**

*Graphics Subroutine:* Sets the color indexes of multiple pixels.

**Module**

USE IFQWIN

**Syntax**

CALL SETPIXELS (n, x, y, color)

- **n** (Input) INTEGER(4). Number of pixels to set. Sets the number of elements in the other arguments.
- **x, y** (Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to set.
- **color** (Input) INTEGER(2). Array containing color indexes to set the pixels to.

SETPIXELS sets the pixels specified in the arrays x and y to the color indexes in color. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If any of the pixels are outside the clipping region, those pixels are ignored. Calls to SETPIXELS with n less than 1 are also ignored. SETPIXELS is a much faster way to set multiple pixel color indexes than individual calls to SETPIXEL.

Unlike SETPIXELS, SETPIXELSRGB gives access to the full color capacity of the system by using direct color values rather than indexes to a palette. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as a Graphics ap.

USE IFQWIN

INTEGER(2) color(9)
INTEGER(2) x(9), y(9), i
DO i = 1, 9
   x(i) = 20 * i
   y(i) = 10 * i
   color(i) = INT2(i)
END DO
CALL SETPIXELS(9, x, y, color)
END

See Also

• S
• GETPIXELS
• SETPIXEL
• SETPIXELSRGB

SETPIXELSRGB (W*32, W*64)

Graphics Subroutine: Sets multiple pixels to the given Red-Green-Blue (RGB) color.

Module

USE IFQWIN

Syntax

CALL SETPIXELSRGB (n,x,y,color)

 n       (Input) INTEGER(4). Number of pixels to be changed. Determines the number of elements in arrays x and y.
 x, y    (Input) INTEGER(2). Parallel arrays containing viewport coordinates of the pixels to set.
**color** (Input) INTEGER(4). Array containing the RGB color values to set the pixels to. Range and result depend on the system's display adapter.

`SETPIXELSRGB` sets the pixels specified in the arrays `x` and `y` to the RGB color values in `color`. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

In each RGB color value, each of the three color values, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you set with `SETPIXELSRGB`, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

```
8 7 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15

<table>
<thead>
<tr>
<th>Bit</th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0 0</td>
<td>B B B B B B B</td>
<td>G G G G G G G</td>
<td>R R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

A good use for `SETPIXELSRGB` is as a buffering form of `SETPIXELRGB`, which can improve performance substantially. The example code shows how to do this.

If any of the pixels are outside the clipping region, those pixels are ignored. Calls to `SETPIXELSRGB` with `n` less than 1 are also ignored.

`SETPIXELSRGB` (and the other RGB color selection functions such as `SETPIXELRGB` and `SETCOLORRGB`) sets colors to values chosen from the entire available range. The non-RGB color functions (such as `SETPIXELS` and `SETCOLOR`) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Buffering replacement for SetPixelRGB and
! SetPixelRGB_W. This can improve performance by
! doing batches of pixels together.
USE IFQWIN
PARAMETER (I$SIZE = 200)
INTEGER(4) bn, bc(I$SIZE), status
INTEGER(2) bx(I$SIZE), by(I$SIZE)
bn = 0
DO i = 1, I$SIZE
  bn = bn + 1
  bx(bn) = i
  by(bn) = i
  bc(bn) = GETCOLORRGB()
  status = SETCOLORRGB(bc(bn)+1)
END DO
CALL SETPIXELSRGB(bn, bx, by, bc)
END

*Building Applications: Color Mixing*
SETTEXTCOLOR (W*32, W*64)

*Graphics Function:* Sets the current text color index.

**Module**

USE IFQWIN

**Syntax**

result = SETTEXTCOLOR (index)

*index* (Input) INTEGER(2). Color index to set the text color to.

**Results**

The result type is INTEGER(2). The result is the previous text color index.

SETTEXTCOLOR sets the current text color index. The default value is 15, which is associated with white unless the user remaps the palette. GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR affects text output with OUTTEXT, WRITE, and PRINT.

The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and SETCOLORRGB.

**NOTE.** The SETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft* Platform SDK version of the SetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN$SetTextColor. For more information, see *Building Applications*: Special Naming Convention for Certain QuickWin and Win32 Graphics Routines.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as a Graphics ap.

USE IFQWIN

INTEGER(2) oldtc

oldtc = SETTEXTCOLOR(INT2(2)) ! green

WRITE(*,*) "hello, world"

END

Building Applications: Using Text Colors

SETTEXTCOLORRGB (W*32, W*64)

Graphics Function: Sets the current text color to the specified Red-Green-Blue (RGB) value.

Module

USE IFQWIN

Syntax

result = SETTEXTCOLORRGB (color)

color (Input) INTEGER(4). RGB color value to set the text color to. Range and result depend on the system’s display adapter.

Results

The result type is INTEGER(4). The result is the previous text RGB color value.
In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value’s internal structure is as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>31 (MSB)</th>
<th>24</th>
<th>23</th>
<th>16</th>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>RGB</td>
<td>0 0 0 0 0 0 0</td>
<td>B B B B B B B</td>
<td>G G G G G G G</td>
<td>R R R R R R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

SETTEXTCOLORRGB sets the current text RGB color. The default value is Z'00FFFFFF', which is full-intensity white. SETTEXTCOLORRGB sets the color used by OUTTEXT, WRITE, and PRINT. It does not affect the color of text output with the OUTGTEXT font routine. Use SETCOLORRGB to change the color of font output.

SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. SETCOLORRGB sets the RGB color value of graphics over the background color, used by the graphics functions such as ARC, FLOODFILLRGB, and OUTGTEXT.

SETTEXTCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB and SETCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETTEXTCOLOR, SETBKCOLOR, and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(4) oldtc
oldtc = SETTEXTCOLORRGB(Z'000000FF')
WRITE(*,*) 'I am red'
oldtc = SETTEXTCOLORRGB(Z'0000FF00')
CALL OUTTEXT ('I am green'//CHAR(13)//CHAR(10))
oldtc = SETTEXTCOLORRGB(Z'00FF0000')
PRINT *, 'I am blue'
END

Building Applications: Using Text Colors

SETTEXTCURSOR (W*32, W*64)

Graphics Function: Sets the height and width of the text cursor (the caret) for the window in focus.

Module
USE IFQWIN

Syntax

result = SETTEXTCURSOR (newcursor)
newcursor

(Input) INTEGER(2). The leftmost 8 bits specify the width of the cursor, and the rightmost 8 bits specify the height of the cursor. These dimensions can range from 1 to 8, and represent a fraction of the current character cell size. For example:

- Z'0808' - Specifies the full character cell; this is the default size.
- Z'0108' - Specifies 1/8th of the character cell width, and 8/8th (or all) of the character cell height.

If either of these dimensions is outside the range 1 to 8, it is forced to 8.

Results

The result type is INTEGER(2); it is the previous text cursor value in the same format as newcursor.

NOTE. After calling SETTEXTCURSOR, you must call DISPLAYCURSOR($GCURSORON) to actually see the cursor.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

use IFQWIN
integer(2) oldcur
integer(2) istat
type(rccoord) rc
open(10, file='user')
istat = displaycursor($GCURSORON)
write(10,*) 'Text cursor is now character cell size, the default.'
read(10,*)
write(10,*) 'Setting text cursor to wide and low.'
oldcur = settextcursor(Z'0801')
istat = displaycursor($GCURSORON)
read(10,*)
write(10,*) 'Setting text cursor to high and narrow.'
oldcur = settextcursor(Z'0108')
istat = displaycursor($GCURSORON)
read(10,*)
write(10,*) 'Setting text cursor to a dot.'
oldcur = settextcursor(Z'0101')
istat = displaycursor($GCURSORON)
read(10,*)
end

See Also

• DISPLAYCURSOR
SETTEXTPOSITION (W*32, W*64)

*Graphics Subroutine:* Sets the current text position to a specified position relative to the current text window.

**Module**

USE IFQWIN

**Syntax**

CALL SETTEXTPOSITION (row, column, t)

*row*  
(Input) INTEGER(2). New text row position.

*column*  
(Input) INTEGER(2). New text column position.

*t*  
(Output) Derived type rccoord. Previous text position. The derived type rccoord is defined in IFQWIN.F90 as follows:

```
TYPE rccoord
    INTEGER(2) row ! Row coordinate
    INTEGER(2) col ! Column coordinate
END TYPE rccoord
```

Subsequent text output with the OUTTEXT function (as well as standard console I/O statements, such as PRINT and WRITE) begins at the point (*row*, *column*).

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

USE IFQWIN

TYPE (rccoord) curpos

WRITE(*,*) "Original text position"

CALL SETTEXTPOSITION (INT2(6), INT2(5), curpos)

WRITE (*,*) 'New text position'

END

Building Applications: Text Coordinates

Building Applications: Using Text Colors

**SETTEXTWINDOW** *(W*32, W*64)*

*Graphics Subroutine:* Sets the current text window.

**Module**

USE IFQWIN

**Syntax**

CALL SETTEXTWINDOW *(r1,c1,r2,c2)*

\[r1, c1\]  (Input) INTEGER(2). Row and column coordinates for upper-left corner of the text window.

\[r2, c2\]  (Input) INTEGER(2). Row and column coordinates for lower-right corner of the text window.

**SETTEXTWINDOW** specifies a window in row and column coordinates where text output to the screen using OUTTEXT, WRITE, or PRINT will be displayed. You set the text location within this window with SETTEXTPOSITION.

Text is output from the top of the window down. When the window is full, successive lines overwrite the last line.

**SETTEXTWINDOW** does not affect the output of the graphics text routine OUTGTEXT. Use the SETVIEWPORT function to control the display area for graphics output.
**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

**Example**

```fortran
USE IFQWIN

TYPE (rccoord) curpos

CALL SETTEXTWINDOW(INT2(5), INT2(1), INT2(7), &
   INT2(40))

CALL SETTEXTPOSITION (INT2(5), INT2(5), curpos)

WRITE(*,*) "Only two lines in this text window"
WRITE(*,*) "so this line will be overwritten"
WRITE(*,*) "by this line"
END
```

**SETTIM**

_Portability Function:_ Sets the system time in your programs. This function is only available on Windows* and Linux* systems.

**Module**

USE IFPORT
Syntax
result = SETTIM (ihr, imin, isec, i100th)

ihr   (Output) INTEGER(4) or INTEGER(2). Hour (0-23).
imin  (Output) INTEGER(4) or INTEGER(2). Minute (0-59).
isec  (Output) INTEGER(4) or INTEGER(2). Second (0-59).
i100th (Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

Results
The result type is LOGICAL(4). The result is .TRUE. if the system time is changed; .FALSE. if no change is made.

NOTE. On Linux systems, you must have root privileges to execute this function.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
LOGICAL(4) success
success = SETTIM(INT2(21),INT2(53+3),&
               INT2(14*2),INT2(88))

END

SETVIEWORG (W*32, W*64)

Graphics Subroutine: Moves the viewport-coordinate origin (0, 0) to the specified physical point.

Module
USE IFQWIN

Syntax
CALL SETVIEWORG (x, y, t)

x, y (Input) INTEGER(2). Physical coordinates of new viewport origin.

y (Output) Derived type xycoord. Physical coordinates of the previous viewport origin. The derived type xycoord is defined in IFQWIN.F90 as follows:

```fortran
TYPE xycoord
    INTEGER(2) xcoord ! x-coordinate
    INTEGER(2) ycoord ! y-coordinate
END TYPE xycoord
```

The xycoord type variable t, defined in IFQWIN.F90, returns the physical coordinates of the previous viewport origin.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example
USE IFQWIN

```fortran
TYPE ( xycoord ) xy
CALL SETVIEWORG(INT2(30), INT2(30), xy)
```

Building Applications: Setting Graphics Coordinates

SETVIEWPORT (W*32, W*64)

Graphics Subroutine: Redefines the graphics viewport by defining a clipping region in the same manner as SETCLIPRGN and then setting the viewport-coordinate origin to the upper-left corner of the region.

Module
USE IFQWIN

Syntax
CALL SETVIEWPORT (x1, y1, x2, y2)

x1, y1 (Input) INTEGER(2). Physical coordinates for upper-left corner of viewport.

x2, y2 (Input) INTEGER(2). Physical coordinates for lower-right corner of viewport.

The physical coordinates (x1, y1) and (x2, y2) are the upper-left and lower-right corners of the rectangular clipping region. Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

USE IFQWIN
INTEGER(2) upx, upy
INTEGER(2) downx, downy
upx = 0
upy = 30
downx = 250
downy = 100
CALL SETVIEWPORT(upx, upy, downx, downy)

- SETCLIPRGN
- SETVIEWORG
- SETWINDOW

Building Applications: Drawing Lines on the Screen
Building Applications: Graphics Coordinates
Building Applications: Setting Graphics Coordinates

SETWINDOW (W*32, W*64)

Graphics Function: Defines a window bound by the specified coordinates.

Module

USE IFQWIN

Syntax

result = SETWINDOW (finvert, wx1, wy1, wx2, wy2)
finvert  (Input) LOGICAL(2). Direction of increase of the y-axis. If finvert is .TRUE., the y-axis increases from the window bottom to the window top (as Cartesian coordinates). If finvert is .FALSE., the y-axis increases from the window top to the window bottom (as pixel coordinates).

wx1, wy1  (Input) REAL(8). Window coordinates for upper-left corner of window.

wx2, wy2  (Input) REAL(8). Window coordinates for lower-right corner of window.

Results

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0 (for example, if the program that calls SETWINDOW is not in a graphics mode).

The SETWINDOW function determines the coordinate system used by all window-relative graphics routines. Any graphics routines that end in _W (such as ARC_W, RECTANGLE_W, and LINETO_W) use the coordinate system set by SETWINDOW.

Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

An arc drawn using inverted window coordinates is not an upside-down version of an arc drawn with the same parameters in a noninverted window. The arc is still drawn counterclockwise, but the points that define where the arc begins and ends are inverted.

If wx1 equals wx2 or wy1 equals wy2, SETWINDOW fails.

Compatibility

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

Example

USE IFQWIN

INTEGER(2) status
LOGICAL(2) invert /.TRUE./
REAL(8) upx /0.0/, upy /0.0/
REAL(8) downx /1000.0/, downy /1000.0/
status = SETWINDOW(invert, upx, upy, downx, downy)

SETWINDOWCONFIG (W*32, W*64)

QuickWin Function: Sets the properties of a child window.

Module
USE IFQWIN

Syntax
result = SETWINDOWCONFIG (wc)
(Input) Derived type windowconfig. Contains window properties. The windowconfig derived type is defined in IFQWIN.F90 as follows:

TYPE windowconfig

  INTEGER(2) numxpixels ! Number of pixels on x-axis.
  INTEGER(2) numypixels ! Number of pixels on y-axis.
  INTEGER(2) numtextcols ! Number of text columns available.
  INTEGER(2) numtextrows ! Number of text rows available.
  INTEGER(2) numcolors ! Number of color indexes.
  INTEGER(4) fontsize ! Size of default font. Set to QWIN$EXTENDFONT when specifying
  ! extended attributes, in which
  ! case extendfontsize sets
  ! font size.
  CHARACTER(80) title ! The window title.
  INTEGER(2) bitsperpixel ! The number of bits per pixel.
  INTEGER(2) numvideopages ! Unused.
  INTEGER(2) mode ! Controls scrolling mode.
  INTEGER(2) adapter ! Unused.
  INTEGER(2) monitor ! Unused.
  INTEGER(2) memory ! Unused.
  INTEGER(2) environment ! Unused.

! The next three parameters provide extended font attributes.

  CHARACTER(32) extendfontname ! The name of the desired font.
  INTEGER(4) extendfontsize ! Takes the same values as
Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The following value can be used to configure a QuickWin window so that it will show the last line written and the text cursor (if it is on):

\[
\text{wc\%mode} = \text{QWIN$SCROLLDOWN}
\]

Note that if you scroll the window to another position, you will have to scroll back to the last line to see your input.

The following values can be used with SETWINDOWCONFIG extended fonts:

**Table 908: Style:**

<table>
<thead>
<tr>
<th>QWIN$EXTENDFONT_NORMAL</th>
<th>Gives no underline, no italic, and a font weight of 400 out of 1000.</th>
</tr>

</table>

**Table 910: Font Families:**

<table>
<thead>
<tr>
<th>QWIN$EXTENDFONT_FF_ROMAN</th>
<th>Variable stroke width, serifed. Times Roman, Century Schoolbook, etc.</th>
</tr>
</thead>
</table>
Variable stroke width, sans-serifed. Helvetica, Swiss, etc.

QuickWin default. Constant stroke width, serifed or sans-serifed. Pica, Elite, Courier, etc.

Cursive, etc.

Old English, etc.

Table 911: Character Sets:

<table>
<thead>
<tr>
<th>Font Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QWIN$EXTENDFONT_FF_SWISS</td>
<td>Variable stroke width, sans-serifed. Helvetica, Swiss, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_MODERN</td>
<td>QuickWin default. Constant stroke width, serifed or sans-serifed. Pica, Elite, Courier, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_SCRIPT</td>
<td>Cursive, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_FF_DECORATIVE</td>
<td>Old English, etc.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_ANSI_CHARSET</td>
<td>QuickWin default.</td>
</tr>
<tr>
<td>QWIN$EXTENDFONT_OEM_CHARSET</td>
<td>Use this to get Microsoft* LineDraw.</td>
</tr>
</tbody>
</table>

Using QWIN$EXTENDFONT_OEM_CHARSET with the font name 'MS LineDraw'C will get the old DOS-style character set with symbols that can be used to draw lines and boxes. The pitch and font family items can be specified to help guide the font matching algorithms used by CreateFontIndirect, the Windows* API used by SETWINDOWCONFIG.

If you use SETWINDOWCONFIG to set the variables in windowconfig to -1, the function sets the highest resolution possible for your system, given the other fields you specify, if any. You can set the actual size of the window by specifying parameters that influence the window size: the number of x and y pixels, the number of rows and columns, and the font size. If you do not call SETWINDOWCONFIG, the window defaults to the best possible resolution and a font size of 8x16. The number of colors available depends on the video driver used.

If you use SETWINDOWCONFIG, you should specify a value for each field (-1 or your own value for the numeric fields and a C string for the title, for example, "words of text"C). Using SETWINDOWCONFIG with only some fields specified can result in useless values for the unspecified fields.

If you request a configuration that cannot be set, SETWINDOWCONFIG returns .FALSE. and calculates parameter values that will work and are as close as possible to the requested configuration. A second call to SETWINDOWCONFIG establishes the adjusted values; for example:

```fortran
  status = SETWINDOWCONFIG(wc)
  if (.NOT.status) status = SETWINDOWCONFIG(wc)
```
If you specify values for all four of the size parameters, `numxpixels`, `numypixel`, `numtextcols`, and `numtextrows`, the font size is calculated by dividing these values. The default font is Courier New and the default font size is 8x16. There is no restriction on font size, except that the window must be large enough to hold it.

Under Standard Graphics, the application attempts to start in Full Screen mode with no window decoration (window decoration includes scroll bars, menu bar, title bar, and message bar) so that the maximum resolution can be fully used. Otherwise, the application starts in a window. You can use ALT+ENTER at any time to toggle between the two modes.

If you are in Full Screen mode and the resolution of the window does not match the resolution of the video driver, graphics output will be slow compared to drawing in a window.

**NOTE.** You must call DISPLAYCURSOR($GCURSORON) to make the cursor visible after calling SETWINDOWCONFIG.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

USE IFQWIN

TYPE (windowconfig) wc
LOGICAL status /.FALSE./
! Set the x & y pixels to 800X600 and font size to 8x12
wc%numxpixels = 800
wc%numypixels = 600
wc%numtextcols = -1
wc%numtextrows = -1
wc%numcolors = -1
wc%title= "This is a test"C
wc%fontsize = '0008000C'
status = SETWINDOWCONFIG(wc) ! attempt to set configuration with above values
    ! if attempt fails, set with system estimated values
if (.NOT.status) status = SETWINDOWCONFIG(wc)

Building Applications: Using Fonts from the Graphics Library Overview
Building Applications: VGA Color Palette
SETWINDOWMENUQQ (W*32, W*64)

QuickWin Function: Sets a top-level menu as the menu to which a list of current child window names is appended.

Module
USE IFQWIN

Syntax
result = SETWINDOWMENUQQ (menuID)

menuID (Input) INTEGER(4). Identifies the menu to hold the child window names, starting with 1 as the leftmost menu.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The list of current child window names can appear in only one menu at a time. If the list of windows is currently in a menu, it is removed from that menu. By default, the list of child windows appears at the end of the Window menu.

Compatibility
QUICKWIN GRAPHICS LIB
Example

USE IFQWIN

TYPE (windowconfig) wc

LOGICAL(4) result, status /.FALSE./

! Set title for child window

wc%numxpixels = -1
wc%numypixels = -1
wc%numtextcols = -1
wc%numtextrows = -1
wc%numcolors = -1
wc%fontsize = -1

wc%title = "I am child window name"

if (.NOT.status) status = SETWINDOWCONFIG(wc)

! put child window list under menu 3 (View)

result = SETWINDOWMENUQQ(3)

END

Building Applications: Program Control of Menus

SETWRITEMODE(W*32, W*64)

Graphics Function: Sets the current logical write mode, which is used when drawing lines with the LINETO, POLYGON, and RECTANGLE functions.

Module

USE IFQWIN
Syntax

\[
\text{result} = \text{SETWRITEMODE}(\text{wmode})
\]

\(\text{wmode}\) (Input) INTEGER(2). Write mode to be set. One of the following symbolic constants (defined in IFQWIN.F90):

- \$GPSET - Causes lines to be drawn in the current graphics color. (Default)
- \$GAND - Causes lines to be drawn in the color that is the logical AND of the current graphics color and the current background color.
- \$GOR - Causes lines to be drawn in the color that is the logical OR of the current graphics color and the current background color.
- \$GPRESET - Causes lines to be drawn in the color that is the logical NOT of the current graphics color.
- \$GXOR - Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the current graphics color and the current background color.

In addition, one of the following binary raster operation constants can be used (described in the online documentation for the Windows* API SetROP2):

- \$GR2_BLACK
- \$GR2_NOTMERGEPEN
- \$GR2_MASKNOTPEN
- \$GR2_NOTCOPYPEN (same as \$GPRESET)
- \$GR2_MASKPENNOT
- \$GR2_NOT
- \$GR2_XORPEN (same as \$GXOR)
- \$GR2_NOTMASKPEN
- \$GR2_MASKPEN (same as \$GAND)
- \$GR2_NOTXORPEN
- \$GR2_NOP
• $GR2_MERGENOTPEN
• $GR2_COPYPEN (same as $GPSET)
• $GR2_MERGEPENNOT
• $GR2_MERGEPEN (same as $GOR)
• $GR2_WHITE

Results
The result type is INTEGER(2). The result is the previous write mode if successful; otherwise, -1.

The current graphics color is set with SETCOLORRGB (or SETCOLOR) and the current background color is set with SETBKCOLORRGB (or SETBKCOLOR). As an example, suppose you set the background color to yellow (Z'00FFFF') and the graphics color to purple (Z'FF00FF') with the following commands:

```fortran
oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')
```

If you then set the write mode with the $GAND option, lines are drawn in red (Z'0000FF'); with the $GOR option, lines are drawn in white (Z'FFFFFF'); with the $GXOR option, lines are drawn in turquoise (Z'FFFF00'); and with the $GPRESET option, lines are drawn in green (Z'00FF00'). Setting the write mode to $GPSET causes lines to be drawn in the graphics color.

Compatibility
STANDARD GRAPHICS QUICKWIN GRAPHICS LIB
Example

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) result, oldmode
INTEGER(4) oldcolor
TYPE (xycoord) xy
oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN ($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')
CALL MOVETO(INT2(0), INT2(0), xy)
result = LINETO(INT2(200), INT2(200)) ! purple
oldmode = SETWRITEMODE( $GAND)
CALL MOVETO(INT2(50), INT2(0), xy)
result = LINETO(INT2(250), INT2(200)) ! red
END

Building Applications: Setting Figure Properties
SETWSIZEQQ (W*32, W*64)

QuickWin Function: Sets the size and position of a window.

Module

USE IFQWIN

Syntax

result = SETWSIZEQQ (unit, winfo)

unit

(Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5, and 6 refer to the default startup window only if the program does not explicitly open them with the OPEN statement. To set the size of the frame window (as opposed to a child window), set unit to the symbolic constant QWIN$FRAMEWINDOW (defined in IFQWIN.F90).

When called from INITIALSETTINGS, SETWSIZEQQ behaves slightly differently than when called from a user routine after initialization. See below under Results.

winfo

(Input) Derived type qwinfo. Physical coordinates of the window's upper-left corner, and the current or maximum height and width of the window's client area (the area within the frame). The derived type qwinfo is defined in IFQWIN.F90 as follows:

```fortran
TYPE QWINFO
  INTEGER(2) TYPE     ! request type
  INTEGER(2) X        ! x coordinate for upper left
  INTEGER(2) Y        ! y coordinate for upper left
  INTEGER(2) H        ! window height
  INTEGER(2) W        ! window width
END TYPE QWINFO
```

This function's behavior depends on the value of QWINFO%TYPE, which can be any of the following:

- **QWIN$MIN** - Minimizes the window.
- **QWIN$MAX** - Maximizes the window.
• QWIN$RESTORE - Restores the minimized window to its previous size.
• QWIN$SET - Sets the window's position and size according to the other values in qwinfo.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero (unless called from INITIALSETTINGS). If called from INITIALSETTINGS, the following occurs:

• SETWSIZEQQ always returns -1.
• Only QWIN$SET will work.

The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.

The height and width specified for a frame window reflects the actual size in pixels of the frame window including any borders, menus, and status bar at the bottom.

Compatibility
QUICKWIN GRAPHICS LIB
Example

USE IFQWIN
INTEGER(4) result
INTEGER(2) numfonts, fontnum
TYPE (qwinfo) winfo
TYPE (xycoord) pos
!

Maximize frame window
winfo%TYPE = QWIN$MAX
result = SETWSIZEQQ(QWIN$FRAMEWINDOW, winfo)
!

Maximize child window
result = SETWSIZEQQ(0, winfo)
numfonts = INITIALIZEFONTS( )
fontnum = SETFONT('t''Arial''h50w34i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT("BIG Window")
END

Building Applications: Using QuickWin Overview
Building Applications: Controlling Size and Position of Windows

SHAPE

*Inquiry Intrinsic Function (Generic):* Returns the shape of an array or scalar argument.

**Syntax**

result = SHAPE (source [, kind])
source   (Input) Is a scalar or array. It may be of any data type. It must not be an assumed-size array, a disassociated pointer, or an allocatable array that is not allocated.

kind   (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result is a rank-one integer array whose size is equal to the rank of source. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is the shape of source.

The setting of compiler options specifying integer size can affect this function.

**Example**

SHAPE (2) has the value of a rank-one array of size zero.

If B is declared as B(2:4, -3:1), then SHAPE (B) has the value (3, 5).
The following shows another example:

```fortran
INTEGER VEC(2)
REAL array(3:10, -1:3)
VEC = SHAPE(array)
WRITE(*,*) VEC ! prints 8 5
END
!
! Check if a mask is conformal with an array
REAL, ALLOCATABLE :: A(:,:,i)
LOGICAL, ALLOCATABLE :: MASK(:,:,i)
INTEGER B(3), C(3)
LOGICAL conform
ALLOCATE (A(5, 4, 3))
ALLOCATE (MASK(3, 4, 5))
! Check if MASK and A allocated. If they are, check
! that they have the same shape (conform).
IF(ALLOCATED(A) .AND. ALLOCATED(MASK)) THEN
    B = SHAPE(A); C = SHAPE(MASK)
    IF ((B(1) .EQ. C(1)) .AND. (B(2) .EQ. C(2))
        .AND. (B(3) .EQ. C(3))) THEN
        conform = .TRUE.
    ELSE
        conform = .FALSE.
    END IF
ELSE
    conform = .FALSE.
END IF
WRITE(*,*) conform ! prints F
END
```
SHARED Clause

Parallel Directive Clause: Specifies variables that will be shared by all the threads in a team.

Syntax

SHARED (list)

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

All threads within a team access the same storage area for SHARED data.

SHIFTL

Elemental Intrinsic Function (Specific):
Logically shifts an integer left by a specified number of bits. This function cannot be passed as an actual argument.

Syntax

result = SHIFTL (ivalue, ishift)

ivalue (Input) Must be of type integer. This is the value to be shifted.

ishift (Input) Must be of type integer. The value must be positive. This value is the number of positions to shift.

Results

The result type is the same as ivalue. The result is the value of ivalue shifted left by ishift bit positions. Bits shifted off the left end are lost; zeros are shifted in from the opposite end.

SHIFTL (i, j) is the same as ISHFT (i, j).

• ISHFT

SHIFTR

*Elemental Intrinsic Function (Specific):*
Logically shifts an integer right by a specified number of bits. This function cannot be passed as an actual argument.

**Syntax**

\[
\text{result} = \text{SHIFTR}(\text{ivalue}, \text{ishift})
\]

- **ivalue** (Input) Must be of type integer. This is the value to be shifted.
- **ishift** (Input) Must be of type integer. The value must be positive. This value is the number of positions to shift.

**Results**

The result type is the same as *ivalue*. The result is the value of *ivalue* shifted right by *ishift* bit positions. Bits shifted off the right end are lost; zeros are shifted in from the opposite end.

SHIFTR (i, j) is the same as ISHFT (i, -j).

**See Also**

- S
- ISHFT

SHORT

*Portability Function: Converts an INTEGER(4) argument to INTEGER(2) type.*

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{SHORT} (\text{int4})
\]

- **int4** (Input) INTEGER(4). Value to be converted.
Results

The result type is INTEGER(2). The result is equal to the lower 16 bits of \texttt{int4}. If the \texttt{int4} value is greater than 32,767, the converted INTEGER(2) value is not equal to the original.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

```fortran
USE IFPORT
INTEGER(4) this_one
INTEGER(2) that_one
READ(*,*) this_one
THAT_ONE = SHORT(THIS_ONE)
WRITE(*,10) THIS_ONE, THAT_ONE
END
```

\textbf{SIGN}

\textit{Elemental Intrinsic Function (Generic):}  
\textit{Returns the absolute value of the first argument times the sign of the second argument.}

\textbf{Syntax}

\[ \text{result} = \text{SIGN} \ (a, b) \]

\(a\) \hspace{1cm} (Input) Must be of type integer or real.

\(b\) \hspace{1cm} (Input) Must have the same type and kind parameters as \(a\).

\textbf{Results}

The result type is the same as \(a\). The value of the result is as follows:
• $|a|$ if $b > 0$ and $-|a|$ if $b < 0$.
• $|a|$ if $b$ is of type integer and is zero.
• If $b$ is of type real and zero and compiler option assume minus0 is not specified, the value of the result is $|a|$.
• If $b$ is of type real and zero and compiler option assume minus0 is specified, the processor can distinguish between positive and negative real zero and the following occurs:
  • If $b$ is positive real zero, the value of the result is $|a|$.
  • If $b$ is negative real zero, the value of the result is $-|a|$.

<table>
<thead>

</tbody>
</table>

\(^1\) Or HSIGN.
\(^2\) Or JISIGN. For compatibility with older versions of Fortran, ISIGN is treated as a generic function.
\(^3\) The setting of compiler options specifying real size can affect SIGN and DSIGN.
\(^4\) The setting of compiler options specifying double size can affect DSIGN.

**Example**
SIGN (4.0, -6.0) has the value -4.0.
SIGN (-5.0, 2.0) has the value 5.0.
The following shows another example:
\[
c = \text{SIGN} (5.2, -3.1) \quad \text{! returns} \quad -5.2
\]
\[
c = \text{SIGN} (-5.2, -3.1) \quad \text{! returns} \quad -5.2
\]
\[
c = \text{SIGN} (-5.2, 3.1) \quad \text{! returns} \quad 5.2
\]

- assume minus0 compiler option

\textbf{SIN}

\textit{Elemental Intrinsic Function (Generic): Produces the sine of} \( x \).

Syntax

\[
\text{result} = \text{SIN} \ (x)
\]

\( x \) \quad (Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*pi.
If \( x \) is of type complex, its real part is regarded as a value in radians.

Results

The result type is the same as \( x \).

<table>
<thead>
<tr>

<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>
The setting of compiler options specifying real size can affect CSIN.

This function can also be specified as ZSIN.

Example

SIN (2.0) has the value 0.9092974.
SIN (0.8) has the value 0.7173561.

**SIND**

*Elemental Intrinsic Function (Generic): Produces the sine of x.*

**Syntax**

```
result = SIND (x)
```

* (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type is the same as x.

<table>
<thead>
<tr>

<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

SIND (2.0) has the value 3.4899496E-02.
SIND (0.8) has the value 1.3962180E-02.
**SINH**

*Elemental Intrinsic Function (Generic):*

*Produces a hyperbolic sine.*

**Syntax**

\[ \text{result} = \text{SINH} \left( x \right) \]

\( x \)  
*(Input) Must be of type real.*

**Results**

The result type is the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SINH</td>

<tr>
<td>DSINH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QSINH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

SINH (2.0) has the value 3.626860.

SINH (0.8) has the value 0.8881060.

**SIGNAL**

*Portability Function: Controls interrupt signal handling. Changes the action for a specified signal.*

**Module**

USE IFPORT

**Syntax**

\[ \text{result} = \text{SIGNAL} \left( \text{signum}, \text{proc}, \text{flag} \right) \]

\( \text{signum} \)  
*(Input) INTEGER(4). Number of the signal to change. The numbers and symbolic names are listed in a table below.*
**proc**  (Input) Name of a signal-processing routine. It must be declared EXTERNAL. This routine is called only if **flag** is negative.

**flag**  (Input) INTEGER(4). If negative, the user’s **proc** routine is called. If 0, the signal retains its default action; if 1, the signal should be ignored.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 and IA-64 architectures. The result is the previous value of **proc** associated with the specified signal. For example, if the previous value of **proc** was SIG_IGN, the return value is also SIG_IGN. You can use this return value in subsequent calls to SIGNAL if the signal number supplied is invalid, if the flag value is greater than 1, or to restore a previous action definition.

A return value of SIG_ERR indicates an error, in which case a call to IERRNO returns EINVAL. If the signal number supplied is invalid, or if the flag value is greater than 1, SIGNAL returns -(EINVAL) and a call to IERRNO returns EINVAL.

An initial signal handler is in place at startup for SIGFPE (signal 8); its address is returned the first time SIGNAL is called for SIGFPE. No other signals have initial signal handlers.

Be careful when you use SIGNALQQ or the C signal function to set a handler, and then use the Portability SIGNAL function to retrieve its value. If SIGNAL returns an address that was not previously set by a call to SIGNAL, you cannot use that address with either SIGNALQQ or C’s signal function, nor can you call it directly. You can, however, use the return value from SIGNAL in a subsequent call to SIGNAL. This allows you to restore a signal handler, no matter how the original signal handler was set.

All signal handlers are called with a single integer argument, that of the signal number actually received. Usually, when a process receives a signal, it terminates. With the SIGNAL function, a user procedure is called instead. The signal handler routine must accept the signal number integer argument, even if it does not use it. If the routine does not accept the signal number argument, the stack will not be properly restored after the signal handler has executed.

Because signal-handler routines are usually called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. You cannot use the following kinds of signal-handler routines:

- Routines that perform low-level (such as FGETC) or high-level (such as READ) I/O.
- Heap routines or any routine that uses the heap routines (such as MALLOC and ALLOCATE).
- Functions that generate a system call (such as TIME).
The following table lists signals, their names and values:

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGABRT</td>
<td>6</td>
<td>Abnormal termination</td>
</tr>
<tr>
<td>SIGFPE</td>
<td>8</td>
<td>Floating-point error</td>
</tr>
<tr>
<td>SIGKILL(^1)</td>
<td>9</td>
<td>Kill process</td>
</tr>
<tr>
<td>SIGILL</td>
<td>4</td>
<td>Illegal instruction</td>
</tr>
<tr>
<td>SIGINT</td>
<td>2</td>
<td>CTRL+C signal</td>
</tr>
<tr>
<td>SIGSEGV</td>
<td>11</td>
<td>Illegal storage access</td>
</tr>
<tr>
<td>SIGTERM</td>
<td>15</td>
<td>Termination request</td>
</tr>
</tbody>
</table>

\(^1\)SIGKILL can be neither caught nor ignored.

The default action for all signals is to terminate the program with exit code.

ABORT does not assert the SIGABRT signal. The only way to assert SIGABRT or SIGTERM is to use KILL.

SIGNAL can be used to catch SIGFPE exceptions, but it cannot be used to access the error code that caused the SIGFPE. To do this, use SIGNALQQ instead.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

EXTERNAL h_abort

INTEGER(4) iret1, iret2, procnum

iret1 = SIGNAL(SIGABRT, h_abort, -1)
WRITE(*,*) 'Set signal handler. Return = ', iret1

iret2 = KILL(procnum, SIGABRT)
WRITE(*,*) 'Raised signal. Return = ', iret2
END

! 
! Signal handler routine 
!

INTEGER(4) FUNCTION h_abort (sig_num)

INTEGER(4) sig_num

WRITE(*,*) 'In signal handler for SIG$ABORT'
WRITE(*,*) 'signum = ', sig_num

h_abort = 1
END

See Also

- S
- SIGNALQQ

SIGNALQQ

Portability Function: Registers the function to be called if an interrupt signal occurs.

Module

USE IFPORT
Syntax

\[\text{result} = \text{SIGNALQQ} \ (\text{sig}, \text{func})\]

\textit{sig} (Input) INTEGER(2). Interrupt type. One of the following constants, defined in \texttt{IFPORT.F90}:
- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+CSIGNAL
- SIG$SEGV - Illegal storage access
- SIG$TERM - Termination request

\textit{func} (Input) Function to be executed on interrupt. It must be declared EXTERNAL.

Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 and IA-64 architectures. The result is a positive integer if successful; otherwise, -1 (SIG$ERR).

SIGNALQQ installs the function \textit{func} as the handler for a signal of the type specified by \textit{sig}. If you do not install a handler, the system by default terminates the program with exit code 3 when an interrupt signal occurs.

The argument \textit{func} is the name of a function and must be declared with either the EXTERNAL or IMPLICIT statements, or have an explicit interface. A function described in an INTERFACE block is EXTERNAL by default, and does not need to be declared EXTERNAL.

\textbf{NOTE.} All signal-handler functions must be declared with the \texttt{cDEC$ \text{ATTRIBUTES C}} option.

When an interrupt occurs, except a SIG$FPE interrupt, the \textit{sig} argument SIG$INT is passed to \textit{func}, and then \textit{func} is executed.
When a SIG$FPE interrupt occurs, the function `func` is passed two arguments: SIG$FPE and the floating-point error code (for example, FPE$ZERODIVIDE or FPE$OVERFLOW) which identifies the type of floating-point exception that occurred. The floating-point error codes begin with the prefix FPE$ and are defined in IFPORT.F90. Floating-point exceptions are described and discussed in *Building Applications: The Floating-Point Environment Overview*.

If `func` returns, the calling process resumes execution immediately after the point at which it received the interrupt signal. This is true regardless of the type of interrupt or operating mode. Because signal-handler routines are normally called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. Therefore, do not call heap routines or any routine that uses the heap routines (for example, I/O routines, ALLOCATE, and DEALLOCATE).

To test your signal handler routine you can generate interrupt signals by calling RAISEQQ, which causes your program either to branch to the signal handlers set with SIGNALQQ, or to perform the system default behavior if SIGNALQQ has set no signal handler.

The example below shows a signal handler for SIG$ABORT. A sample signal handler for SIG$FPE is given in *Building Applications: Handling Floating-Point Exceptions*.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

! This program shows a signal handler for SIG$ABORT

USE IFPORT

INTERFACE
    FUNCTION h_abort (signum)
        !DEC$ ATTRIBUTES C :: h_abort
        INTEGER(4) h_abort
        INTEGER(2) signum
    END FUNCTION
END INTERFACE

INTEGER(2) i2ret
INTEGER(4) i4ret
i4ret = SIGNALQQ(SIG$ABORT, h_abort)
WRITE(*,*) 'Set signal handler. Return = ', i4ret
i2ret = RAISEQQ(SIG$ABORT)
WRITE(*,*) 'Raised signal. Return = ', i2ret
END

! Signal handler routine
!

INTEGER(4) FUNCTION h_abort (signum)
    !DEC$ ATTRIBUTES C :: h_abort
    INTEGER(2) signum
    WRITE(*,*) 'In signal handler for SIG$ABORT'
    WRITE(*,*) 'signum = ', signum
    h_abort = 1
END

SINGLE

OpenMP® Fortran Compiler Directive: Specifies that a block of code is to be executed by only one thread in the team.

Syntax

c$OMP SINGLE [clause[,, clause] ... ]

block

c$OMP END SINGLE [modifier]

c Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

clause Is one of the following:

- FIRSTPRIVATE (list)
- PRIVATE (list)

block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

modifier Is one of the following:

- COPYPRIVATE (list)
- NOWAIT

Threads in the team that are not executing this directive wait at the END SINGLE directive unless NOWAIT is specified.

SINGLE directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.
Example

In the following example, the first thread that encounters the SINGLE directive executes subroutines OUTPUT and INPUT:

```fortran
C$OMP PARALLEL DEFAULT(SHARED)
   CALL WORK(X)
C$OMP BARRIER
C$OMP SINGLE
   CALL OUTPUT(X)
   CALL INPUT(Y)
C$OMP END SINGLE
   CALL WORK(Y)
C$OMP END PARALLEL
```

You should not make assumptions as to which thread executes the SINGLE section. All other threads skip the SINGLE section and stop at the barrier at the END SINGLE construct. If other threads can proceed without waiting for the thread executing the SINGLE section, you can specify NOWAIT in the END SINGLE directive.

SIZE Function

*Inquiry Intrinsic Function (Generic):* Returns the total number of elements in an array, or the extent of an array along a specified dimension.

**Syntax**

```fortran
result = SIZE (array [, dim] [, kind])
```

*array* (Input) Must be an array. It may be of any data type. It must not be a disassociated pointer or an allocatable array that is not allocated. It can be an assumed-size array if *dim* is present with a value less than the rank of *array*.
The result is a scalar of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If dim is present, the result is the extent of dimension dim in array; otherwise, the result is the total number of elements in array.

The setting of compiler options specifying integer size can affect this function.

Example

If B is declared as B(2:4, -3:1), then SIZE (B, DIM=2) has the value 5 and SIZE (B) has the value 15.

The following shows another example:

```
REAL(8) array (3:10, -1:3)
INTEGER i
i = SIZE(array, DIM = 2) ! returns 5
i = SIZE(array) ! returns 40
```

See Also

- SHAPE
- Character Count Specifier

SIZEOF

*Inquiry Intrinsic Function (Generic):* Returns the number of bytes of storage used by the argument. It cannot be passed as an actual argument.

Syntax

```
result = SIZEOF (x)
```
x  (Input) Can be a scalar or array. It may be of any data type. It must not be an assumed-size array.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. The result value is the number of bytes of storage used by x.

Example
SIZEOF (3.44)  ! has the value 4
SIZEOF ('SIZE')  ! has the value 4

SLEEP
Portability Subroutine: Suspends the execution of a process for a specified interval.

Module
USE IFPORT

Syntax
CALL SLEEP (time)

(time)  (Input) INTEGER(4). Length of time, in seconds, to suspend the calling process.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

integer(4) hold_time
hold_time = 1 ! lets the loop execute
DO WHILE (hold_time .NE. 0)
   write(*,'(A)') "Enter the number of seconds to suspend"
   read(*,*) hold_time
   CALL SLEEP (hold_time)
END DO
END

See Also

• S
• SLEEPQQ

SLEEPQQ

Portability Subroutine: Delays execution of the program for a specified duration.

Module

USE IFPORT

Syntax

CALL SLEEPQQ (duration)

duration (Input) INTEGER(4). Number of milliseconds the program is to sleep (delay program execution).

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

INTEGER(4) delay, freq, duration

delay = 2000
freq = 4000
duration = 1000

CALL SLEEPQQ(delay)
CALL BEEPQQ(freq, duration)

END

SNGL

See REAL function.

SORTQQ

Portability Subroutine: Sorts a one-dimensional array. The array elements cannot be derived types or record structures.

Module

USE IFPORT

Syntax

CALL SORTQQ (adrarray, count, size)

adrarray

to be certain that SORTQQ is successful, compare the value returned in count to the value you provided. If they are the same, then SORTQQ sorted the correct number of elements.
**size**  
(Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in IFPORT.F90, specify type and kind for numeric arrays:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL8</td>
<td>REAL(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL16</td>
<td>REAL(16) or equivalent</td>
</tr>
</tbody>
</table>

If the value provided in **size** is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with **size** characters per element.

---

**CAUTION.** The location of the array must be passed by address using the LOC function. This defeats Fortran type-checking, so you must make certain that the **count** and **size** arguments are correct.

If you pass invalid arguments, SORTQQ attempts to sort random parts of memory. If the memory it attempts to sort is allocated to the current process, that memory is sorted; otherwise, the operating system intervenes, the program is halted, and you get a General Protection Violation message.

---

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

! Sort a 1-D array
!
USE IFPORT
INTEGER(2) array(10)
INTEGER(2) i
DATA ARRAY /143, 99, 612, 61, 712, 9112, 6, 555, 222, 67/
! Sort the array
Call SORTQQ (LOC(array), 10, SRT$INTEGER2)
! Display the sorted array
DO i = 1, 10
   WRITE (*, 9000) i, array (i)
9000 FORMAT(1X, ' Array(',I2, '): ', I5)
END DO
END

SPACING

Elemental Intrinsic Function (Generic):
Returns the absolute spacing of model numbers near the argument value.

Syntax
result = SPACING (x)

x           (Input) Must be of type real.
**Results**

The result type is the same as \( x \). The result has the value \( b \times 10^{e-p} \). Parameters \( b \), \( e \), and \( p \) are defined in Model for Real Data. If the result value is outside of the real model range, the result is TINY\( ( x ) \).

**Example**

If 3.0 is a REAL(4) value, SPACING(3.0) has the value \( 2^{-22} \).

The following shows another example:

```fortran
REAL(4) res4
REAL(8) res8, r2
res4 = SPACING(3.0) ! returns 2.384186E-07
res4 = SPACING(-3.0) ! returns 2.384186E-07
r2 = 487923.3
res8 = SPACING(r2) ! returns 5.820766091346741E-011
```

**See Also**

- S
- TINY
- RRSPACING

**SPLITPATHQQ**

**Portability Function:** Breaks a file path or directory path into its components.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SPLITPATHQQ (path, drive, dir, name, ext)
```

- **path** *(Input) Character*\(^*(*)\). Path to be broken into components. Forward slashes (/), backslashes (\), or both can be present in \( path \).

- **drive** *(Output) Character*\(^*(*)\). Drive letter followed by a colon.
dir (Output) Character(*) (*). Path of directories, including the trailing slash.

name (Output) Character(*) (*). Name of file or, if no file is specified in path, name of the lowest directory. A file name must not include an extension.

ext (Output) Character(*) (*). File name extension, if any, including the leading period (.)

Results
The result type is INTEGER(4). The result is the length of dir.

The path parameter can be a complete or partial file specification.

$MAXPATH is a symbolic constant defined in module IFPORT.F90 as 260.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
CHARACTER($MAXPATH) buf
CHARACTER(3) drive
CHARACTER(256) dir
CHARACTER(256) name
CHARACTER(256) ext
CHARACTER(256) file
INTEGER(4) length
buf = 'b:\fortran\test\runtime\tsplit.for'
length = SPLITPATHQQ(buf, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
file = 'partial.f90'
length = SPLITPATHQQ(file, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
END
SPORT_CANCEL_IO (W*32, W*64)

Serial Port I/O Function: Cancels any I/O in progress to the specified port.

Module
USE IFPORT

Syntax
result = SPORT_CANCEL_IO (port)

port (Input) Integer. The port number.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

NOTE. This call also kills the thread that keeps an outstanding read operation to the serial port. This call must be done before any of the port characteristics are modified.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CANCEL_IO( 2 )
END

Communications and Communications Functions in the Microsoft* Platform SDK
**SPORT_CONNECT (W*32, W*64)**

**Serial Port I/O Function:** Establishes the connection to a serial port and defines certain usage parameters.

**Module**

USE IFPORT

**Syntax**

```plaintext
result = SPORT_CONNECT (port [,options])
```

- **port** (Input) Integer. The port number of connection. The routine will open COM \( n \), where \( n \) is the port number specified.
- **options** (Input; optional) Integer. Defines the connection options. These options define how the \( \text{nnn}_{-}\text{LINE} \) routines will work and also effect the data that is passed to the user. If more than one option is specified, the operator `.OR.` should be used between each option. Options are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL_TOSS_CR</td>
<td>Removes carriage return (CR) characters on input.</td>
</tr>
<tr>
<td>DL_TOSS_LF</td>
<td>Removes linefeed (LF) characters on input.</td>
</tr>
<tr>
<td>DL_OUT_CR</td>
<td>Causes SPORT_WRITE_LINE to add a CR to each record written.</td>
</tr>
<tr>
<td>DL_OUT_LF</td>
<td>Causes SPORT_WRITE_LINE to add a LF to each record written.</td>
</tr>
<tr>
<td>DL_TERM_CR</td>
<td>Causes SPORT_READ_LINE to terminate READ when a CR is encountered.</td>
</tr>
</tbody>
</table>
If `options` is not specified, the following occurs by default:

\[(\text{DL\_OUT\_CR} \text{ OR } \text{DL\_TERM\_CR} \text{ OR } \text{DL\_TOSS\_CR} \text{ OR } \text{DL\_TOSS\_LF})\]

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

**Results**
The result type is `INTEGER(4)`. The result is zero if successful; otherwise, a Windows* error value.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CONNECT( 2 )
END
```

**See Also**
- `S`
- `SPORT_RELEASE`, Communications and Communications Functions in the Microsoft* Platform SDK

*Building Applications*: Using the Serial I/O Port Routines
**SPORT_CONNECT_EX (W*32, W*64)**

**Serial Port I/O Function:** Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception.

**Module**

USE IFPORT

**Syntax**

result = SPORT_CONNECT_EX (port [,options] [,BufferSize])

- **port** (Input) Integer. The port number of connection. The routine will open COM \( n \), where \( n \) is the port number specified.
- **options** (Input; optional) Integer. Defines the connection options. These options define how the \( nnn\_LINE \) routines will work and also effect the data that is passed to the user. If more than one option is specified, the operator .OR. should be used between each option. Options are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DL_TOSS_CR</td>
<td>Removes carriage return (CR) characters on input.</td>
</tr>
<tr>
<td>DL_TOSS_LF</td>
<td>Removes linefeed (LF) characters on input.</td>
</tr>
<tr>
<td>DL_OUT_CR</td>
<td>Causes SPORT_WRITE_LINE to add a CR to each record written.</td>
</tr>
<tr>
<td>DL_OUT_LF</td>
<td>Causes SPORT_WRITE_LINE to add a LF to each record written.</td>
</tr>
<tr>
<td>DL_TERM_CR</td>
<td>Causes SPORT_READ_LINE to terminate READ when a CR is encountered.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DL_TERM_LF</td>
<td>Causes SPORT_READ_LINE to terminate READ when a LF is encountered.</td>
</tr>
<tr>
<td>DL_TERM_CRLF</td>
<td>Causes SPORT_READ_LINE to terminate READ when CR+LF is encountered.</td>
</tr>
</tbody>
</table>

If `options` is not specified, the following occurs by default:

\[(DL_OUT_CR \ OR \ DL_TERM_CR \ OR \ DL_TOSS_CR \ OR \ DL_TOSS_LF)\]

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

`BufferSize`

(Input; optional) Integer. Size of the internal buffer for data reception. If `BufferSize` is not specified, the size of the buffer is 16384 bytes (the default).

The size of the buffer must be 4096 bytes or larger. If you try to specify a size smaller than 4096 bytes, your specification will be ignored and the buffer size will be set to 4096 bytes.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```
USE IFPORT

INTEGER(4) iresult

iresult = SPORT_CONNECT_EX( 2, BufferSize = 8196 )

END
```

**See Also**

SPORT_GET_STATE (W*32, W*64)

Serial Port I/O Function: Returns the baud rate, parity, data bits setting, and stop bits setting of the communications port.

Module

USE IFPORT

Syntax

result = SPORT_GET_STATE (port [,baud] [,parity] [,dbits] [,sbits])

port
(Input) Integer. The port number.

baud
(Output; optional) Integer. The baud rate of the port.

parity
(Output; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).

dbits
(Output; optional) Integer. The data bits for the port.

sbits
(Output; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example
USE IFPORT
INTEGER(4) iresult
INTEGER baud
INTEGER parity
INTEGER dbits
INTEGER sbits
iresult = SPORT_GET_STATE( 2, baud, parity, dbits, sbits )
END

```

- **port** (Input) Integer. The port number.
- **present** (Output; optional) Integer. 1 if data is present, 0 if no data has been read.
- **count** (Output; optional) Integer. The count of characters that will be returned by SPORT_READ_DATA.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

This routine will only return when a line terminator has been seen - as defined by the mode specified in the SPORT_CONNECT( ) call.

**NOTE.** CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

INTEGER(4) iresult
INTEGER present
INTEGER count

iresult = SPORT_PEEK_LINE( 2, present, count )

END

Communications and Communications Functions in the Microsoft* Platform SDK

Building Applications: Using the Serial I/O Port Routines

SPORT_PURGE (W*32, W*64)

Serial Port I/O Function: Executes the Windows* API communications function PurgeComm on the specified port.

Module

USE IFPORT

Syntax

result = SPORT_PURGE (port, function)

port (Input) Integer. The port number.
function (Input) INTEGER(4). The function for PurgeComm (see the Windows documentation).

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.
Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFWINTY
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_PURGE( 2, (PURGE_TXABORT .or. PURGE_RXABORT) )
END

Building Applications: Using the Serial I/O Port Routines

SPORT_READ_DATA (W*32, W*64)

Serial Port I/O Function: Reads available data from the specified port. This routine stalls until at least one character has been read.

Module

USE IFPORT

Syntax

result = SPORT_READ_DATA (port,buffer[,count])

port (Input) Integer. The port number.
buffer (Output) Character*(*) . The data that was read.
count (Output; optional) Integer. The count of bytes read.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.
NOTE. CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
INTEGER(4) iresult
INTEGER count
CHARACTER*1024 rbuff
iresult = SPORT_READ_DATA( 2, rbuff, count )
END

Building Applications: Using the Serial I/O Port Routines

SPORT_READ_LINE(W^32, W^64)

Serial Port I/O Function: Reads a record from the specified port. This routine stalls until at least one record has been read.

Module
USE IFPORT

Syntax
result = SPORT_READ_LINE (port, buffer[, count])
**port**  
(Input) Integer. The port number.

**buffer**  
(Output) Character*(*). The data that was read.

**count**  
(Output; optional) Integer. The count of bytes read.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

This routine will only return when a line terminator has been seen - as defined by the mode specified in the SPORT_CONNECT( ) call.

**NOTE.** CR and LF characters may not be returned depending on the mode specified in the SPORT_CONNECT( ) call.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```plaintext
USE IPORT
INTEGER(4) iresult
INTEGER count
CHARACTER*1024 rbuff
iresult = SPORT_READ_LINE( 2, rbuff, count )
END
```

Communications and Communications Functions in the Microsoft* Platform SDK

*Building Applications: Using the Serial I/O Port Routines*
SPORT_SET_STATE (W*32, W*64)

Serial Port I/O Function: Sets the baud rate, parity, data bits setting, and stop bits setting of the communications port.

Module

USE IFPORT

Syntax

result = SPORT_SET_STATE (port [,baud] [,parity] [,dbits] [,sbits])

port  (Input) Integer. The port number.
baud  (Input; optional) Integer. The baud rate of the port.
parity (Input; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).
dbits (Input; optional) Integer. The data bits for the port.
sbits (Input; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

The following restrictions apply:

- The number of data bits must be 5 to 8 bits.
- The use of 5 data bits with 2 stop bits is an invalid combination, as is 6, 7, or 8 data bits with 1.5 stop bits.

NOTE. This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

INTEGER(4) iresult
iresult = SPORT_SET_STATE( 2, 9600, 0, 7, 1 )
END

Building Applications: Using the Serial I/O Port Routines

Communications, Communications Functions, and SetCommState in the Microsoft* Platform SDK

SPORT_SET_STATE_EX(W*32, W*64)

Serial Port I/O Function: Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.

Module

USE IFPORT

Syntax

result = SPORT_SET_STATE_EX (port [,baud] [,parity] [,dbits] [,sbits]
[,Binmode] [,DTRcntrl]
[,XonLim]
[,XonChar] [,XoffChar]
[,ErrChar] [,EofChar] [,EvtChar] [,fZeroDCB])

port (Input) Integer. The port number.
baud (Input; optional) Integer. The baud rate of the port.
parity (Input; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).

dbits (Input; optional) Integer. The data bits for the port.

sbits (Input; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

Binmode (Input; optional) Integer. 1 if binary mode should be enabled; otherwise, 0. Currently, if this parameter is used, the value must be 1.

DTRcntrl (Input; optional) Integer. 1 if DTR (data-terminal-ready) flow control should be used; otherwise, 0.

RTScntrl (Input; optional) Integer. 1 if RTS (request-to-send) flow control should be used; otherwise, 0.

OutCTSFlow (Input; optional) Integer. 1 if the CTS (clear-to-send) signal should be monitored for output flow control; otherwise, 0.

OutDSRFlow (Input; optional) Integer. 1 if the DSR (data-set-ready) signal should be monitored for output flow control; otherwise, 0.

DSRSense (Input; optional) Integer. 1 if the communications driver should be sensitive to the state of the DSR signal; otherwise, 0.

OutXonOff (Input; optional) Integer. 1 if XON/XOFF flow control should be used during transmission; otherwise, 0.

InXonOff (Input; optional) Integer. 1 if XON/XOFF flow control should be used during reception; otherwise, 0.

XonLim (Input; optional) Integer. The minimum number of bytes that should be accepted in the input buffer before the XON character is set.

XoffLim (Input; optional) Integer. The maximum number of bytes that should be accepted in the input buffer before the XOFF character is set.

TXContOnXoff (Input; optional) Integer. 1 if transmission should be stopped when the input buffer is full and the driver has transmitted the XoffChar character; otherwise, 0.

ErrAbort (Input; optional) Integer. 1 if read and write operations should be terminated when an error occurs; otherwise, 0.

ErrCharEnbl (Input; optional) Integer. 1 if bytes received with parity errors should be replaced with the ErrChar character; otherwise, 0.
NullStrip (Input; optional) Integer. 1 if null bytes should be discarded; otherwise, 0.

XonChar (Input; optional) Character. The value of the XON character that should be used for both transmission and reception.

XoffChar (Input; optional) Character. The value of the XOFF character that should be used for both transmission and reception.

ErrChar (Input; optional) Character. The value of the character that should be used to replace bytes received with parity errors.

EofChar (Input; optional) Character. The value of the character that should be used to signal the end of data.

EvtChar (Input; optional) Character. The value of the character that should be used to signal an event.

fZeroDCB (Input; optional) Integer. 1 if all settings of the communications port should be set to zero before parameters are set; otherwise, 0.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

The following restrictions apply:

- The number of data bits must be 5 to 8 bits.
- The use of 5 data bits with 2 stop bits is an invalid combination, as is 6, 7, or 8 data bits with 1.5 stop bits.

**NOTE.** This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
**Example**

```fortran
USE IFPORT

INTEGER(4) iresult

iresult = SPORT_SET_STATE_EX( 2, 9600, 0, 7, 1, OutXonOff=1, InXonOff=1, 
    & XonLim=1024, XoffLim=512, XonChar=CHAR(17), XoffChar=CHAR(19), & 
    fZeroDCB=1) 

END
```

**SPORT_SET_TIMEOUTS (W*32, W*64)**

*Serial Port I/O Function*: Sets the user selectable timeouts for the serial port.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SPORT_SET_TIMEOUTS (port [,rx_int] [,tx_tot_mult] [,tx_tot_const])
```

- **port** (Input) Integer. The port number.
- **rx_int** (Input; optional) INTEGER(4). The receive interval timeout value.
- **tx_tot_mult** (Input; optional) INTEGER(4). The transmit multiplier part of the timeout value.
- **tx_tot_const** (Input; optional) INTEGER(4). The transmit constant part of the timeout value.
Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

NOTE. This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT

INTEGER(4) iresult

iresult = SPORT_SET_TIMEOUTS( 2, 100, 0, 1000 )

END

Building Applications: Using the Serial I/O Port Routines

SPORT_SHOW_STATE (W*32, W*64)

Serial Port I/O Function: Displays the state of a port to standard output.

Module

USE IFPORT

Syntax

result = SPORT_SHOW_STATE (port, level)
port
level

(Input) Integer. The port number.

(Input) Integer. Controls the level of detail displayed as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Basic one line display</td>
</tr>
<tr>
<td>1</td>
<td>Basic information</td>
</tr>
<tr>
<td>2</td>
<td>Add modem signal control flow information</td>
</tr>
<tr>
<td>3</td>
<td>Add XON/XOFF information</td>
</tr>
<tr>
<td>4</td>
<td>Add event character information</td>
</tr>
<tr>
<td>11</td>
<td>Add timeout information</td>
</tr>
<tr>
<td>901</td>
<td>Add debug information</td>
</tr>
</tbody>
</table>

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

NOTE. This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT_CANCEL_IO before port parameters can be changed.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SHOW_STATE( 2, 0 )
END

Communications and Communications Functions in the Microsoft® Platform SDK

Building Applications: Using the Serial I/O Port Routines

SPORT_SPECIAL_FUNC (W*32, W*64)

**Serial Port I/O Function:** Executes the Windows® API communications function EscapeCommFunction on the specified port.

**Module**

USE IFPORT

**Syntax**

```
result = SPORT_SPECIAL_FUNC (port, function)
```

*port*  (Input) Integer. The port number.

*function*  (Input) INTEGER(4). The function to perform.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, the result is a Windows® error value.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```
USE IFPORT

INTEGER(4) iresult

iresult = SPORT_SPECIAL_FUNC( 2, ? )

END
```

See Also

- S
SPORT_WRITE_DATA (W*32, W*64)

Serial Port I/O Function: Outputs data to the specified port.

Module

USE IFPORT

Syntax

result = SPORT_WRITE_DATA (port, data[, count])

- **port** (Input) Integer. The port number.
- **data** (Input) Character*(*) . The data to be output.
- **count** (Input; optional) Integer. The count of bytes to write. If the value is zero, this number is computed by scanning the data backwards looking for a non-blank character.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

**NOTE.** When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions SPORT_WRITE_DATA and SPORT_WRITE_LINE can write less bytes than required. When this occurs, the functions return the code ERROR_IO_INCOMPLETE, and the return value of parameter count contains the number of bytes that were really written.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT

INTEGER(4) iresult
iresult = SPORT_WRITE_DATA( 2, 'ATZ//CHAR(13), 0 )
END

See Also

• S
• SPORT_WRITE_LINE
• SPORT_READ_DATA

Communications and Communications Functions in the Microsoft* Platform SDK

Building Applications: Using the Serial I/O Port Routines

SPORT_WRITE_LINE (W*32, W*64)

Serial Port I/O Function: Outputs data, followed by a record terminator, to the specified port.

Module

USE IFPORT

Syntax

result = SPORT_WRITE_LINE (port, data[, count])

port (Input) Integer. The port number.
data (Input) Character*(*). The data to be output.
count (Input; optional) Integer. The count of bytes to write. If the value is zero, this number is computed by scanning the data backwards looking for a non-blank character.

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows* error value.

After the data is output, a line terminator character is added based on the mode used during the SPORT_CONNECT( ) call.
NOTE. When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions SPORT_WRITE_DATA and SPORT_WRITE_LINE can write less bytes than required. When this occurs, the functions return the code ERROR_IO_INCOMPLETE, and the return value of parameter count contains the number of bytes that were really written.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example
USE IPORT
INTEGER(4) iresult
iresult = SPORT_WRITE_LINE( 2, 'ATZ', 0 )
END

See Also
• S
• SPORT_CONNECT
• SPORT_WRITE_DATA
• SPORT_READ_DATA

Communications and Communications Functions in the Microsoft* Platform SDK
Building Applications: Using the Serial I/O Port Routines

SPREAD
Transformational Intrinsic Function (Generic):
Creates a replicated array with an added dimension by making copies of existing elements along a specified dimension.

Syntax
result = SPREAD (source, dim, ncopies)

source (Input) Must be a scalar or array. It may be of any data type. The rank must be less than 7.
Must be scalar and of type integer. It must have a value in the range 1 to n + 1 (inclusive), where n is the rank of source.

ncopies

Must be scalar and of type integer. It becomes the extent of the additional dimension in the result.

Results

The result is an array of the same type as source and of rank that is one greater than source.

If source is an array, each array element in dimension dim of the result is equal to the corresponding array element in source.

If source is a scalar, the result is a rank-one array with ncopies elements, each with the value source.

If ncopies less than or equal to zero, the result is an array of size zero.

Example

SPREAD ("B", 1, 4) is the character array ("B", "B", "B", "B").

B is the array (3, 4, 5) and NC has the value 4.

SPREAD (B, DIM=1, NCOPIES=NC) produces the array

\[
\begin{bmatrix}
3 & 4 & 5 \\
3 & 4 & 5 \\
3 & 4 & 5 \\
3 & 4 & 5 \\
\end{bmatrix}
\]

SPREAD (B, DIM=2, NCOPIES=NC) produces the array

\[
\begin{bmatrix}
3 & 3 & 3 & 3 \\
4 & 4 & 4 & 4 \\
5 & 5 & 5 & 5 \\
\end{bmatrix}
\]
The following shows another example:

```fortran
INTEGER AR1(2, 3), AR2(3, 2)
AR1 = SPREAD((/1,2,3/),DIM= 1,NCOPIES= 2) ! returns
   ! 1 2 3
   ! 1 2 3
AR2 = SPREAD((/1,2,3/), 2, 2) ! returns 1 1
   ! 2 2
   ! 3 3
```

See Also
- S
- PACK
- RESHAPE

**SQRT**

*Elemental Intrinsic Function (Generic):*

*Produces the square root of its argument.*

**Syntax**

```fortran
result = SQRT (x)
```

- \( x \) (Input) must be of type real or complex. If \( x \) is type real, its value must be greater than or equal to zero.

**Results**

The result type is the same as \( x \). The result has a value equal to the square root of \( x \). A result of type complex is the principal value, with the real part greater than or equal to zero. When the real part of the result is zero, the imaginary part of the result has the same sign as the imaginary part of \( x \), even if the imaginary part of \( x \) is a negative real zero.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQRT</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DSQRT</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QSQRT</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
<tr>
<td>Specific Name</td>

<tr>
<td>CDSQRT (^2)</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQSQT</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect CSQRT.
\(^2\)This function can also be specified as ZSQRT.

Example

SQRT (16.0) has the value 4.0.

SQRT (3.0) has the value 1.732051.

The following shows another example:

```fortran
! Calculate the hypotenuse of a right triangle
! from the lengths of the other two sides.
REAL sidea, sideb, hyp
sidea = 3.0
sideb = 4.0
hyp = SQRT (sidea**2 + sideb**2)
WRITE (*, 100) hyp
100 FORMAT (/ ' The hypotenuse is ', F10.3)
END
```

SRAND

Portability Subroutine: Seeds the random number generator used with IRAND and RAND.

Module

USE IFPORT
Syntax

CALL SRAND (iseed)

iseed (Input) INTEGER(4). Any value. The default value is 1.

SRAND seeds the random number generator used with IRAND and RAND. Calling SRAND is equivalent to calling IRAND or RAND with a new seed.

The same value for iseed generates the same sequence of random numbers. To vary the sequence, call SRAND with a different iseed value each time the program is executed.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

! How many random numbers out of 100 will be between .5 and .6?
USE IFPORT
ICOUNT = 0
CALL SRAND(123)
DO I = 1, 100
   X = RAND(0)
   IF ((X>.5).AND.(x<.6)) ICOUNT = ICOUNT + 1
END DO
WRITE(*,*) ICOUNT, "numbers between .5 and .6!"
END

SSWRQQ

**Portability Subroutine:** Returns the floating-point processor status word.

**Module**

USE IFPORT

**Syntax**

CALL SSWRQQ (status)

*status* (Output) INTEGER(2). Floating-point processor status word.

SSWRQQ performs the same function as the run-time subroutine GETSTATUSFPQQ and is provided for compatibility.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFPORT

INTEGER(2) status

CALL SSWRQQ (status)

**See Also**

- S
- LCWRQQ
- GETSTATUSFPQQ

**STAT**

**Portability Function:** Returns detailed information about a file.

**Module**

USE IFPORT
Syntax

\texttt{result = STAT (name, statb)}

\textit{name} \hspace{2cm} (Input) Character*(*). Name of the file to examine.

\textit{statb} \hspace{2cm} (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of \textit{statb} contain the following values:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
</table>
| statb(1) | Device the file resides on | W*32, W*64: Always 0  
|          |             | L*X, M*X: System dependent |
| statb(2) | File inode number | W*32, W*64: Always 0  
|          |             | L*X, M*X: System dependent |
| statb(3) | Access mode of the file | See the table in Results |
| statb(4) | Number of hard links to the file | W*32, W*64: Always 1  
|          |             | L*X, M*X: System dependent |
| statb(5) | User ID of owner | W*32, W*64: Always 1  
|          |             | L*X, M*X: System dependent |
| statb(6) | Group ID of owner | W*32, W*64: Always 1  
<p>|          |             | L<em>X, M</em>X: System dependent |</p>
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>statb(7)</td>
<td>Raw device the file resides on</td>
<td>W<em>32, W</em>64: Always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: System dependent</td>
</tr>
<tr>
<td>statb(8)</td>
<td>Size of the file</td>
<td></td>
</tr>
<tr>
<td>statb(9)</td>

<td>W<em>32, W</em>64: Only available on non-FAT file systems; undefined on FAT systems</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: System dependent</td>
</tr>
<tr>
<td>statb(10)</td>
<td>Time when the file was last modified(^1)</td>
<td></td>
</tr>
<tr>
<td>statb(11)</td>
<td>Time of last file status change(^1)</td>
<td>W<em>32, W</em>64: Same as stat(10)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: System dependent</td>
</tr>
<tr>
<td>statb(12)</td>
<td>Blocksize for file system I/O operations</td>
<td>W<em>32, W</em>64: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: System dependent</td>
</tr>
</tbody>
</table>

\(^1\)Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).

**Results**

The result type is INTEGER(4).
On Windows* systems, the result is zero if the inquiry was successful; otherwise, the error code ENOENT (the specified file could not be found). On Linux* and Mac OS* X systems, the file inquired about must be currently connected to a logical unit and must already exist when STAT is called; if STAT fails, *errno* is set.

For a list of other error codes, see *IERRNO*.

The access mode (the third element of *stat*) is a bitmap consisting of an IOR of the following constants:

<table>
<thead>
<tr>
<th>Symbolic name</th>

</tbody>
</table>

STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

On Windows systems, LSTAT returns exactly the same information as STAT. On Linux and Mac OS X systems, if the file denoted by `name` is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.
You can also use the INQUIRE statement to get information about file properties.

**Compatibility**
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
USE IFPORT

CHARACTER*12 file_name
INTEGER(4) info_array(12)
print *, 'Enter file to examine: '
read *, file_name
ISTATUS = STAT (file_name, info_array)
if (.not. istatus) then
    print *, info_array
else
    print *, 'Error = ', istatus
end if
end
```

**See Also**
- `S`
- `INQUIRE`
- `GETFILEINFOQQ`
- `FSTAT`

**Statement Function**

**Statement**: Defines a function in a single statement in the same program unit in which the procedure is referenced.

**Syntax**

```fortran
fun([d-arg [,d-arg]...]) = expr
```

`fun` is the name of the statement function.
\[ d-arg \]
Is a dummy argument. A dummy argument can appear only once in any list of dummy arguments, and its scope is local to the statement function.

\[ expr \]
Is a scalar expression defining the computation to be performed. Named constants and variables used in the expression must have been declared previously in the specification part of the scoping unit or made accessible by use or host association.
If the expression contains a function or statement function reference, that function must have been defined previously as a function or statement function in the same program unit.
A statement function reference takes the following form:

\[ \text{fun}([ \ a-arg[\ , \ a-arg\ ]\ ...]) \]

\[ \text{fun} \]
Is the name of the statement function.

\[ a-arg \]
Is an actual argument.

**Description**

When a statement function reference appears in an expression, the values of the actual arguments are associated with the dummy arguments in the statement function definition. The expression in the definition is then evaluated. The resulting value is used to complete the evaluation of the expression containing the function reference.

The data type of a statement function can be explicitly defined in a type declaration statement. If no type is specified, the type is determined by implicit typing rules in effect for the program unit.

Actual arguments must agree in number, order, and data type with their corresponding dummy arguments.

Except for the data type, declarative information associated with an entity is not associated with dummy arguments in the statement function; for example, declaring an entity to be an array or to be in a common block does not affect a dummy argument with the same name.

The name of the statement function cannot be the same as the name of any other entity within the same program unit.

Any reference to a statement function must appear in the same program unit as the definition of that function.

A statement function reference must appear as (or be part of) an expression. The reference cannot appear on the left side of an assignment statement.

A statement function must not be provided as a procedure argument.
Example

The following are examples of statement functions:

```fortran
REAL VOLUME, RADIUS
VOLUME(RADIUS) = 4.189*RADIUS**3
CHARACTER*10 CSF,A,B
CSF(A,B) = A(6:10)//B(1:5)
```

The following example shows a statement function and some references to it:

```fortran
AVG(A,B,C) = (A+B+C)/3.
...
GRADE = AVG(TEST1,TEST2,XLAB)
IF (AVG(P,D,Q) .LT. AVG(X,Y,Z)) STOP
FINAL = AVG(TEST3,TEST4,LAB2) ! Invalid reference; implicit
... ! type of third argument does not
... ! match implicit type of dummy argument
```

Implicit typing problems can be avoided if all arguments are explicitly typed.

The following statement function definition is invalid because it contains a constant, which cannot be used as a dummy argument:

```fortran
REAL COMP, C, D, E
COMP(C,D,E,3.) = (C + D - E)/3.
```

The following shows another example:

```fortran
Add (a, b) = a + b
REAL(4) y, x(6)
...
DO n = 2, 6
  x(n) = Add (y, x(n-1))
END DO
```

Use and Host Association

STATIC

Statement and Attribute: Controls the storage allocation of variables in subprograms (as does AUTOMATIC). Variables declared as STATIC and allocated in memory reside in the static storage area, rather than in the stack storage area.

Syntax
The STATIC attribute can be specified in a type declaration statement or a STATIC statement, and takes one of the following forms:

Type Declaration Statement:

```
type, [att-ls,] STATIC [, att-ls] :: v[, v] ...
```

Statement:

```
STATIC[..] v[, v] ...
```

- **type** Is a data type specifier.
- **att-ls** Is an optional list of attribute specifiers.
- **v** Is the name of a variable or an array specification. It can be of any type.

STATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.

By default, the compiler allocates local scalar variables of non-recursive subprograms in the static storage area. Local arrays, except for allocatable arrays, are in the static storage area by default.

The compiler may choose to allocate a variable in temporary (stack or register) storage if it notices that the variable is always defined before use. Appropriate use of the SAVE attribute can prevent compiler warnings if a variable is used before it is defined.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
As an option in an OPTIONS statement

To override any compiler option that may affect variables, explicitly specify the variables as STATIC.

**NOTE.** Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as STATIC more than once in the same scoping unit.

If the variable is a pointer, STATIC applies only to the pointer itself, not to any associated target.

Some variables cannot be specified as STATIC. The following table shows these restrictions:

<table>
<thead>
<tr>
<th>Variable</th>
<th>STATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dummy argument</td>
<td>No</td>
</tr>
<tr>
<td>Automatic object</td>
<td>No</td>
</tr>
<tr>
<td>Common block item</td>
<td>Yes</td>
</tr>
<tr>
<td>Use-associated item</td>
<td>No</td>
</tr>
<tr>
<td>Function result</td>
<td>No</td>
</tr>
<tr>
<td>Component of a derived type</td>
<td>No</td>
</tr>
</tbody>
</table>

A variable can be specified with both the STATIC and SAVE attributes.

If a variable is in a module's outer scope, it can be specified as STATIC.

**Example**

The following example shows a type declaration statement specifying the STATIC attribute:

```
INTEGER, STATIC :: ARRAY_A
```
The following example uses a STATIC statement:

... CONTAINS

INTEGER FUNCTION REDO_FUNC
  INTEGER I, J(10), K
  REAL C, D, E(30)
  AUTOMATIC I, J, K(20)
  STATIC C, D, E

... END FUNCTION

... CONTAINS

INTEGER N1, N2
N1 = -1
DO WHILE (N1)
  N2 = N1*2
  call sub1(N1, N2)
  read *, N1
END DO

CONTAINS

SUBROUTINE sub1 (iold, inew)
  INTEGER, intent(INOUT):: iold
  integer, STATIC :: N3
  integer, intent(IN) :: inew
  if (iold .eq. -1) then
    N3 = iold
  end if
  print *, 'New: ', inew, 'N3: ', N3
END subroutine

!
STOP

**Statement:** Terminates program execution before the end of the program unit.

**Syntax**

STOP [stop-code]

*stop-code* (Optional) A message. It can be either of the following:

- A scalar character constant of type default character.
- A non-negative integer less than or equal to 2147483647; leading zeros are ignored. (The Fortran standard limits stop-code to at most five digits.)

If *stop-code* is specified, the STOP statement does the following:

- Writes the specified message to the standard error device.
- Writes one or more of the following messages to the standard error device indicating which IEEE floating-point exceptions are signaling:
  - IEEE_DIVIDE_BY_ZERO is signaling
  - IEEE_INVALID is signaling
  - IEEE_OVERFLOW is signaling
• IEEE_UNDERFLOW is signaling

• Terminates program execution. If stop-code is a character constant, a status of zero is returned. If stop-code is an integer, a status equal to stop-code is returned.

If stop-code is not specified, the program is terminated, no message is printed, and a status of zero is returned.

**Effect on Windows* Systems**

In QuickWin programs, the following is displayed in a message box:

Program terminated with Exit Code stop-code

**Effect on Linux* and Mac OS* Systems**

Operating system shells (such as bash, sh, csh, etc.) work with one byte exit status. So, when stop-code is an integer, only the lowest byte is significant. For example, consider the following statement:

STOP 99999

In this case, the program returns a status equal to 159 because integer 99999 = Z'1869F', and the lowest byte is equal to Z'9F', which equals 159.

**Example**

The following examples show valid STOP statements:

STOP 98

STOP 'END OF RUN'

DO

READ *, X, Y

IF (X > Y) STOP 5555

END DO

The following shows another example:

OPEN(1,FILE='file1.dat', status='OLD', ERR=100)

...  

100 STOP 'ERROR DETECTED!'

END

**STRICT and NOSTRICT**

*General Compiler Directive:* **STRICT** disables language features not found in the language standard specified on the command line (Fortran 2003, Fortran 95, or Fortran 90). **NOSTRICT** (the default) enables these features.

**Syntax**

```
c DEC$ STRICT
nc DEC$ NOSTRICT
```

Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

If **STRICT** is specified and no language standard is specified on the command line, the default is to disable features not found in Fortran 2003.

The **STRICT** and **NOSTRICT** directives can appear only at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. **STRICT** and **NOSTRICT** cannot appear between program units, or at the beginning of internal subprograms. They do not affect any modules invoked with the **USE** statement in the program unit that contains them.
Example

! NOSTRICT by default

TYPE stuff
  INTEGER(4) k
  INTEGER(4) m
  CHARACTER(4) name
END TYPE stuff

TYPE (stuff) examp
DOUBLE COMPLEX cd ! non-standard data type, no error
cd = (3.0D0, 4.0D0)
examp.k = 4 ! non-standard component designation,
         ! no error
END

SUBROUTINE STRICTDEMO( )
  !DEC$ STRICT
  TYPE stuff
    INTEGER(4) k
    INTEGER(4) m
    CHARACTER(4) name
END TYPE stuff
  TYPE (stuff) samp
DOUBLE COMPLEX cd ! ERROR
cd = (3.0D0, 4.0D0)
samp.k = 4 ! ERROR
END SUBROUTINE

Building Applications: Compiler Directives Related to Options

STRUCTURE...END STRUCTURE

Statement: Defines the field names, types of data within fields, and order and alignment of fields within a record structure. Fields and structures can be initialized, but records cannot be initialized.

Syntax

STRUCTURE [/structure-name/] [field-namelist]
  field-declaration
  [field-declaration]
  . . .
  [field-declaration]
END STRUCTURE

structure-name

Is the name used to identify a structure, enclosed by slashes. Subsequent RECORD statements use the structure name to refer to the structure. A structure name must be unique among structure names, but structures can share names with variables (scalar or array), record fields, PARAMETER constants, and common blocks. Structure declarations can be nested (contain one or more other structure declarations). A structure name is required for the structured declaration at the outermost level of nesting, and is optional for the other declarations nested in it. However, if you wish to reference a nested structure in a RECORD statement in your program, it must have a name.

Structure, field, and record names are all local to the defining program unit. When records are passed as arguments, the fields in the defining structures within the calling and called subprograms must match in type, order, and dimension.

field-namelist

Is a list of fields having the structure of the associated structure declaration. A field namelist is allowed only in nested structure declarations.
field-declaration Also called the declaration body. A field-declaration consists of any combination of the following:

- **Type declarations**
  These are ordinary Fortran data type declarations.

- **Substructure declarations**
  A field within a structure can be a substructure composed of atomic fields, other substructures, or a combination of both.

- **Union declarations**
  A union declaration is composed of one or more mapped field declarations.

- **PARAMETER statements**
  PARAMETER statements can appear in a structure declaration, but cannot be given a data type within the declaration block.

Type declarations for PARAMETER names must precede the PARAMETER statement and be outside of a STRUCTURE declaration, as follows:

```fortran
INTEGER*4 P
STRUCTURE /ABC/
  PARAMETER (P=4)
  REAL*4 F
END STRUCTURE
REAL*4 A(P)
```

The Fortran 90 derived type replaces STRUCTURE and RECORD constructs, and should be used in writing new code. See Derived Data Types.

Unlike type declaration statements, structure declarations do not create variables. Structured variables (records) are created when you use a RECORD statement containing the name of a previously declared structure. The RECORD statement can be considered as a kind of type declaration statement. The difference is that aggregate items, not single items, are being defined.

Within a structure declaration, the ordering of both the statements and the field names within the statements is important, because this ordering determines the order of the fields in records.
In a structure declaration, each field offset is the sum of the lengths of the previous fields, so the length of the structure is the sum of the lengths of its fields. The structure is packed; you must explicitly provide any alignment that is needed by including, for example, unnamed fields of the appropriate length.

By default, fields are aligned on natural boundaries; misaligned fields are padded as necessary. To avoid padding of records, you should lay out structures so that all fields are naturally aligned.

To pack fields on arbitrary byte boundaries, you must specify a compiler option. You can also specify alignment for fields by using the OPTIONS or PACK general directive.

A field name must not be the same as any intrinsic or user-defined operator (for example, EQ cannot be used as a field name).

Compatibility

An item can be a RECORD statement that references a previously defined structure type:

```plaintext
STRUCTURE /full_address/
  RECORD /full_name/ personsname
  RECORD /address/ ship_to
  INTEGER*1 age
  INTEGER*4 phone
END STRUCTURE
```

You can specify a particular item by listing the sequence of items required to reach it, separated by a period (.). Suppose you declare a structure variable, `shippingaddress`, using the `full_address` structure defined in the previous example:

```plaintext
RECORD /full_address/ shippingaddress
```

In this case, the `age` item would then be specified by `shippingaddress.age`, the first name of the receiver by `shippingaddress.personsname.first_name`, and so on.
In the following example, the declaration defines a structure named \texttt{APPOINTMENT}.

\texttt{APPOINTMENT}\ contains the structure \texttt{DATE} \texttt{(field APP\_DATE)} as a substructure. It also contains a substructure named \texttt{TIME} \texttt{(field APP\_TIME, an array)}, a \texttt{CHARACTER*20} array named \texttt{APP\_MEMO}, and a \texttt{LOGICAL*1} field named \texttt{APP\_FLAG}.

\begin{verbatim}
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
END STRUCTURE

STRUCTURE /APPOINTMENT/
  RECORD /DATE/   APP\_DATE
  STRUCTURE /TIME/ APP\_TIME (2)
    INTEGER*1 HOUR, MINUTE
  END STRUCTURE
  CHARACTER*20 APP\_MEMO (4)
  LOGICAL*1 APP\_FLAG
END STRUCTURE
\end{verbatim}

The length of any instance of structure \texttt{APPOINTMENT} is 89 bytes.
The following figure shows the memory mapping of any record or record array element with the structure `APPOINTMENT`. 
Figure 100: Memory Map of Structure APPOINTMENT
(byte offset)

0  field DAY of field APP_DATE
1  field MONTH of field APP_DATE
2  field YEAR of field APP_DATE
3  
4  field HOUR of field APP_TIME(1)
5  field MINUTE of field APP_TIME(1)
6  field HOUR of field APP_TIME(2)
7  field MINUTE of field APP_TIME(2)
8  field APP_MEMO(1)

28  field APP_MEMO(2)

48  field APP_MEMO(3)

68  field APP_MEMO(4)

88  field APP_FLAG

89  

ZK-1848-GE
SUBROUTINE

**Statement:** The initial statement of a subroutine subprogram. A subroutine subprogram is invoked in a CALL statement or by a defined assignment statement, and does not return a particular value.

**Syntax**

\[
[prefix \ [prefix]] \text{SUBROUTINE name } \{(\text{d-arg-list}) \ [\text{lang-binding}]\}
\]

\[
[\text{specification-part}]
\]

\[
[\text{execution-part}]
\]

[CONTAINS]

\[
\text{internal-subprogram-part}
\]

END [SUBROUTINE [name]]

**prefix**

(Optional) Is any of the following:

- **RECURSIVE**
  Permits direct recursion to occur.
- **PURE**
  Asserts that the procedure has no side effects.
- **ELEMENTAL**
Acts on one array element at a time. This is a restricted form of pure procedure.

At most one of each of the above can be specified. You cannot specify ELEMENTAL and RECURSIVE together. You cannot specify ELEMENTAL if lang-binding is specified.

name
Is the name of the subroutine.

d-arg-list
(Optional) Is a list of one or more dummy arguments or alternate return specifiers (*).

lang-binding
(Optional) Takes the following form:
BIND (C [, NAME=ext-name])

ext-name
Is a character scalar initialization expression that can be used to construct the external name.

specification-part
Is one or more specification statements, except for the following:

- INTENT (or its equivalent attribute)
- OPTIONAL (or its equivalent attribute)
- PUBLIC and PRIVATE (or their equivalent attributes)

An automatic object must not appear in a specification statement. If a SAVE statement is specified, it has no effect.

execution-part
Is one or more executable constructs or statements, except for ENTRY or RETURN statements.

internal-subprogram-part
Is one or more internal subprograms (defining internal procedures). The internal-subprogram-part is preceded by a CONTAINS statement.

Description

A subroutine is invoked by a CALL statement or defined assignment. When a subroutine is invoked, dummy arguments (if present) become associated with the corresponding actual arguments specified in the call.

Execution begins with the first executable construct or statement following the SUBROUTINE statement. Control returns to the calling program unit once the END statement (or a RETURN statement) is executed.
A subroutine subprogram cannot contain a BLOCK DATA statement, a PROGRAM statement, or a MODULE statement. A subroutine can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

You need an interface block for a subroutine when:

- Calling arguments use argument keywords.
- Some arguments are optional.
- A dummy argument is an assumed-shape array, a pointer, or a target.
- The subroutine extends intrinsic assignment.
- The subroutine can be referenced by a generic name.
- The subroutine is in a dynamic-link library.

If the subroutine is in a DLL and is called from your program, use the option DLLEXPORT or DLLIMPORT, which you can specify with the ATTRIBUTES directive.

Note that if you specify lang-binding, you have to use the parentheses even if there are no arguments. For example, without lang-binding you can specify SUBROUTINE F but with lang-binding you have to specify SUBROUTINE F( ) BIND (C).

Example

The following example shows a subroutine:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL HELLO_WORLD</td>
<td>SUBROUTINE HELLO_WORLD</td>
</tr>
<tr>
<td>...</td>
<td>PRINT *, &quot;Hello World&quot;</td>
</tr>
<tr>
<td>END</td>
<td>END SUBROUTINE</td>
</tr>
</tbody>
</table>
The following example uses alternate return specifiers to determine where control transfers on completion of the subroutine:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subroutine</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL CHECK(A,B,*10,*20,C)</td>
<td>SUBROUTINE CHECK(X,Y,<em>,</em>,*,Q)</td>
</tr>
<tr>
<td>TYPE *, 'VALUE LESS THAN ZERO'</td>
<td>...</td>
</tr>
<tr>
<td>GO TO 30</td>
<td>50 IF (Z) 60,70,80</td>
</tr>
<tr>
<td>10 TYPE*, 'VALUE EQUALS ZERO'</td>
<td>60 RETURN</td>
</tr>
<tr>
<td>GO TO 30</td>
<td>70 RETURN 1</td>
</tr>
<tr>
<td>20 TYPE*, 'VALUE MORE THAN ZERO'</td>
<td>80 RETURN 2</td>
</tr>
<tr>
<td>30 CONTINUE</td>
<td>END</td>
</tr>
</tbody>
</table>

The SUBROUTINE statement argument list contains two dummy alternate return arguments corresponding to the actual arguments *10 and *20 in the CALL statement argument list. The value of Z determines the return, as follows:

- If Z < zero, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the main program.
- If Z = = zero, the return is to statement label 10 in the main program.
- If Z > zero, the return is to statement label 20 in the main program.

(An alternate return is an obsolescent feature in Fortran 90 and Fortran 95.)

The following shows another example:

```fortran
SUBROUTINE GetNum (num, unit)
    INTEGER num, unit
    10 READ (unit, '(I10)', ERR = 10) num
END
```

**See Also**

- S
- FUNCTION
- INTERFACE
- PURE
SUM

Transformational Intrinsic Function (Generic):
Returns the sum of all the elements in an entire array or in a specified dimension of an array.

Syntax

\[
\text{result} = \text{SUM}(\text{array }, \text{dim} \ [, \text{mask}])
\]

- \text{array} (Input) Must be an array of type integer, real, or complex.
- \text{dim} (Input; optional) Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of \text{array}.
- \text{mask} (Input; optional) Must be of type logical and conformable with \text{array}.

Results

The result is an array or a scalar of the same data type as \text{array}.
The result is a scalar if \text{dim} is omitted or \text{array} has rank one.
The following rules apply if \text{dim} is omitted:

- If \text{SUM}(\text{array}) is specified, the result is the sum of all elements of \text{array}. If \text{array} has size zero, the result is zero.
- If \text{SUM}(\text{array}, \text{MASK=} \text{mask}) is specified, the result is the sum of all elements of \text{array} corresponding to true elements of \text{mask}. If \text{array} has size zero, or every element of \text{mask} has the value .FALSE., the result is zero.

The following rules apply if \text{dim} is specified:

- If \text{array} has rank one, the value is the same as \text{SUM}(\text{array}[,\text{MASK=} \text{mask}]).
An array result has a rank that is one less than array, and shape \((d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n)\), where \((d_1, d_2, \ldots, d_n)\) is the shape of array.

The value of element \((s_1, s_2, \ldots, s_{\text{dim}-1}, s_{\text{dim}+1}, \ldots, s_n)\) of \(\text{SUM}(\text{array}, \text{dim}[, \text{mask}])\) is equal to \(\text{SUM}(\text{array}(s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n) [, \text{MASK} = \text{mask}(s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n)]\).

**Example**

\(\text{SUM}((/2, 3, 4/))\) returns the value 9 (sum of 2 + 3 + 4). \(\text{SUM}((/2, 3, 4/), \text{DIM}=1)\) returns the same result.

\(\text{SUM}(B, \text{MASK}=B \cdot \text{LT. 0.0})\) returns the arithmetic sum of the negative elements of B.

C is the array

\[
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{bmatrix}
\]

\(\text{SUM}(C, \text{DIM}=1)\) returns the value (5, 7, 9), which is the sum of all elements in each column. 5 is the sum of 1 + 4 in column 1. 7 is the sum of 2 + 5 in column 2, and so forth.

\(\text{SUM}(C, \text{DIM}=2)\) returns the value (6, 15), which is the sum of all elements in each row. 6 is the sum of 1 + 2 + 3 in row 1. 15 is the sum of 4 + 5 + 6 in row 2.

The following shows another example:

```fortran
INTEGER array (2, 3), i, j(3)
array = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
! array is 1 3 5
! 2 4 6
i = SUM((/ 1, 2, 3 /)) ! returns 6
j = SUM(array, DIM = 1) ! returns [3 7 11]
WRITE(*,*) i, j
END
```

**SWP and NOSWP (i64 only)**

**General Compiler Directives:** *SWP* enables software pipelining for a DO loop. *NOSWP* (the default) disables this software pipelining. These directives are only available on IA-64 architecture.

**Syntax**

```
DEC$ SWP
DEC$ NOSWP
```

* `c` Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

The SWP directive must precede the DO statement for each DO loop it affects.

The SWP directive does not help data dependence, but overrides heuristics based on profile counts or lop-sided control flow.

The software pipelining optimization specified by the SWP directive applies instruction scheduling to certain innermost loops, allowing instructions within a loop to be split into different stages.

This allows increased instruction level parallelism, which can reduce the impact of long-latency operations, resulting in faster loop execution.

Loops chosen for software pipelining are always innermost loops containing procedure calls that are inlined. Because the optimizer no longer considers fully unrolled loops as innermost loops, fully unrolling loops can allow an additional loop to become the innermost loop (see compiler option `-funroll-loops` or `/Qunroll`).

You can request and view the optimization report to see whether software pipelining was applied.
Example

```fortran
!DEC$ SWP

do i = 1, m
    if (a(i) .eq. 0) then
        b(i) = a(i) + 1
    else
        b(i) = a(i)/c(i)
    endif
enddo
```

*Optimizing Applications*: Pipelining for Itanium®-based Architecture

*Optimizing Applications*: Optimizer Report Generation

**SYSTEM**

*Portability Function*: Sends a command to the shell as if it had been typed at the command line.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SYSTEM (string)
```

**string** (Input) Character*. Operating system command.

**Results**

The result type is INTEGER(4). The result is the exit status of the shell command. If -1, use IERRNO to retrieve the error. Errors can be one of the following:
• E2BIG: The argument list is too long.
• ENOENT: The command interpreter cannot be found.
• ENOEXEC: The command interpreter file has an invalid format and is not executable.
• ENOMEM: Not enough system resources are available to execute the command.

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess() in your Fortran code.

Commands run with the SYSTEM routine are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The command line character limit for the SYSTEM function is the same limit that your operating system command interpreter accepts.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
INTEGER(4) I, errnum
I = SYSTEM("dir > file.lst")
If (I .eq. -1) then
        errnum = ierrno()
        print *, 'Error ', errnum
end if
END

See Also

• SYSTEMQQ
**SYSTEM_CLOCK**

**Intrinsic Subroutine**: Returns integer data from a real-time clock. **SYSTEM_CLOCK** returns the number of seconds from 00:00 Coordinated Universal Time (CUT) on 1 JAN 1970. The number is returned with no bias. To get the elapsed time, you must call **SYSTEM_CLOCK** twice, and subtract the starting time value from the ending time value.

**Syntax**

CALL SYSTEM_CLOCK ([count] [, count_rate] [, count_max])

- **count** (Output; optional) Must be scalar and of type integer. It is set to a value based on the current value of the processor clock. The value is increased by one for each clock count until the value **count_max** is reached, and is reset to zero at the next count. (count lies in the range 0 to **count_max**.)

- **count_rate** (Output; optional) Must be scalar and of type integer. It is set to the number of processor clock counts per second. If the type is INTEGER(2), **count_rate** is 1000. If the type is INTEGER(4), **count_rate** is 10000. If the type is INTEGER(8), **count_rate** is 1000000.

- **count_max** (Output; optional) Must be scalar and of type integer. It is set to the maximum value that **count** can have, HUGE(0).

All arguments used must have the same integer kind parameter. If the type is INTEGER(1), **count**, **count_rate**, and **count_max** are all zero, indicating that there is no clock available to Intel Fortran with an 8-bit range.
Example
Consider the following:

```fortran
integer(2) :: ic2, crate2, cmax2
integer(4) :: ic4, crate4, cmax4

call system_clock(count=ic2, count_rate=crate2, count_max=cmax2)
call system_clock(count=ic4, count_rate=crate4, count_max=cmax4)
print *, ic2, crate2, cmax2
print *, ic4, crate4, cmax4
end
```

This program was run on Thursday Dec 11, 1997 at 14:23:55 EST and produced the following output:

```
13880 1000 32767
1129498807 10000 2147483647
```

See Also
- DATE_AND_TIME
- HUGE
- GETTIM

**SYSTEMQQ**

*Portability Function:* Executes a system command by passing a command string to the operating system’s command interpreter.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SYSTEMQQ (commandline)
```

*commandline* (Input) Character*(*) Command to be passed to the operating system.
**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The SYSTEMQQ function lets you pass operating-system commands as well as programs. SYSTEMQQ refers to the COMSPEC and PATH environment variables that locate the command interpreter file (usually named COMMAND.COM).

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess( ) in your Fortran code.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- **ERR$2BIG** - The argument list exceeds 128 bytes, or the space required for the environment formation exceeds 32K.
- **ERR$NOINT** - The command interpreter cannot be found.
- **ERR$NOEXEC** - The command interpreter file has an invalid format and is not executable.
- **ERR$NOMEM** - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

The command line character limit for the SYSTEMQQ function is the same limit that your operating system command interpreter accepts.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

```fortran
USE IFPORT
LOGICAL(4) result

result = SYSTEMQQ('copy c:\bin\fmath.dat &
                   c:\dat\fmath2.dat')
```

TAN

*Elemental Intrinsic Function (Generic): Produces the tangent of x.*

**Syntax**

\[
\text{result} = \text{TAN}(x)
\]

\(x\) (Input) Must be of type real or complex. If \(x\) is of type real, it must be in radians and is treated as modulo \(2 \times \pi\). If \(x\) is of type complex, its real part is regarded as a value in radians.

**Results**

The result type is the same as \(x\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>TAN</td>
<td>REAL(4)</td>
<td>REAL(4)</td>

<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQTAN</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

\(^1\) The setting of compiler options specifying real size can affect CTAN.

\(^2\) This function can also be specified as ZTAN.

**Example**

TAN (2.0) has the value -2.185040.

TAN (0.8) has the value 1.029639.
**TAND**

*Elemental Intrinsic Function (Generic):*
*Produces the tangent of x.*

**Syntax**

\[ \text{result} = \text{TAND} (x) \]

\( x \)  
(Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type is the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

</tr>
<tr>
<td>QTAND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

TAND (2.0) has the value 3.4920771E-02.
TAND (0.8) has the value 1.3963542E-02.

**TANH**

*Elemental Intrinsic Function (Generic):*
*Produces a hyperbolic tangent.*

**Syntax**

\[ \text{result} = \text{TANH} (x) \]

\( x \)  
(Input) Must be of type real.

**Results**

The result type is the same as \( x \).
<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>TANH</td>

<td>DTANH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QTANH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example
TANH (2.0) has the value 0.9640276.
TANH (0.8) has the value 0.6640368.

TARGET

**Statement and Attribute:** Specifies that an object can become the target of a pointer (it can be pointed to).

Syntax
The TARGET attribute can be specified in a type declaration statement or a TARGET statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls], TARGET [], att-ls] :: object[(a-spec)] [ , object[(a-spec)]] ...
```

**Statement:**

```
TARGET [], object[(a-spec)] [ , object[(a-spec)]] ...
```

*type* 
Is a data type specifier.

*att-ls* 
Is an optional list of attribute specifiers.

*object* 
Is the name of the object. The object must not be declared with the PARAMETER attribute.

*a-spec* 
(Optional) Is an array specification.

Description
A pointer is associated with a target by pointer assignment or by an ALLOCATE statement.

If an object does not have the TARGET attribute or has not been allocated (using an ALLOCATE statement), no part of it can be accessed by a pointer.
Example

The following example shows type declaration statements specifying the TARGET attribute:

\[
\text{TYPE(SYSTEM), TARGET :: FIRST}
\]

\[
\text{REAL, DIMENSION(20, 20), TARGET :: C, D}
\]

The following is an example of a TARGET statement:

\[
\text{TARGET :: C(50, 50), D}
\]

The following fragment is from the program POINTER2.F90 in the <install-dir>/samples subdirectory:

\[
! \text{An example of pointer assignment.}
\]

\[
\text{REAL, POINTER :: arrow1 (:)}
\]

\[
\text{REAL, POINTER :: arrow2 (:)}
\]

\[
\text{REAL, ALLOCATABLE, TARGET :: bullseye (:)}
\]

\[
\text{ALLOCATE (bullseye (?:)}
\]

\[
\text{bullseye = 1.}
\]

\[
\text{bullseye (1:7:2) = 10.}
\]

\[
\text{WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye}
\]

\[
\text{arrow1 => bullseye}
\]

\[
\text{WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow1}
\]

...

**TASK**

*OpenMP* Fortran Compiler Directive: Defines a task region.

**Syntax**

```fortran
$OMP TASK [clause[, clause] ... ]
  block
$OMP END TASK
```

- `c` is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).
- `clause` is one of the following:
  - `DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)`
  - `FIRSTPRIVATE (list)`
  - `IF ( scalar_logical_expression )`
    - Specifies that the enclosed code section is to be executed in parallel only if the `scalar_logical_expression` evaluates to `.TRUE.`. If this clause is not used, the region is executed as if an `IF(.TRUE.)` clause were specified.
    - If the `scalar_logical_expression` evaluates to `.FALSE.`, the encountering thread must suspend the current task region and begin execution of the generated task immediately. The suspended task region will not be resumed until the generated task is completed.
    - This clause is evaluated by the master thread before any data scope attributes take effect.
    - Only a single IF clause can appear in the directive.
  - `PRIVATE (list)`
  - `SHARED (list)`
  - `UNTIED`
Specifies the task is never tied to the thread that started its execution. Any thread in the team can resume the task region after a suspension. For example, during runtime, the compiler can start the execution of a given task on thread A, break execution and later resume it on thread B.

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block (the parallel region).

The TASK and END TASK directive pair must appear in the same routine in the executable section of the code.

The END TASK directive denotes the end of the task.

When a thread encounters a task construct, a task is generated from the code for the associated structured block. The encountering thread may immediately execute the task, or defer its execution. In the latter case, any thread in the team may be assigned the task.

A task construct may be nested inside an outer task, but the task region of the inner task is not a part of the task region of the outer task.

The task construct includes a task scheduling point in the task region of its generating task, immediately following the generation of the explicit task. Each explicit task region includes a task scheduling point at its point of completion.

Note that when storage is shared by an explicit task region, you must add proper synchronization to ensure that the storage does not reach the end of its lifetime before the explicit task region completes its execution.
Example

The following example calculates a Fibonacci number. The Fibonacci sequence is 1,1,2,3,5,8,13, etc., where the current number is the sum of the previous two numbers. If a call to function fib is encountered by a single thread in a parallel region, a nested task region will be spawned to carry out the computation in parallel.

```fortran
RECURSIVE INTEGER FUNCTION fib(n)
  INTEGER n, i, j
  IF ( n .LT. 2) THEN
    fib = n
  ELSE
    !$OMP TASK SHARED(i)
    i = fib( n-1 )
    !$OMP END TASK
    !$OMP TASK SHARED(j)
    j = fib( n-2 )
    !$OMP END TASK
    !$OMP TASKWAIT ! wait for the sub-tasks to complete before summing
    fib = i+j
  END IF
END FUNCTION
```
The following example generates a large number of tasks in one thread and executes them with the threads in the parallel team. While generating these tasks, if the implementation reaches the limit generating unassigned tasks, the generating loop may be suspended and the thread used to execute unassigned tasks. When the number of unassigned tasks is sufficiently low, the thread resumes execution of the task generating loop.

```fortran
real*8 item(10000000)
integer i
!
!$omp parallel
!$omp single ! loop iteration variable i is private
    do i=1,10000000
!$omp task
! i is firstprivate, item is shared
    call process(item(i))
!$omp end task
    end do
!$omp end single
!$omp end parallel
end
```
The following example modifies the previous one to use an untied task to generate the unassigned tasks. If the implementation reaches the limit generating unassigned tasks and the generating loop is suspended, any other thread that becomes available can resume the task generation loop.

```fortran
real*8 item(10000000)
!$omp parallel
!$omp single
!$omp task untied
  ! loop iteration variable i is private
    do i=1,10000000
      !$omp task ! i is firstprivate, item is shared
        call process(item(i))
      !$omp end task
    end do
!$omp end task
!$omp end single
!$omp end parallel
```

**See Also**
- T to Z
- OpenMP Fortran Compiler Directives
- OpenMP* Fortran Routines
- PARALLEL DO
- TASKWAIT
- SHARED Clause

**TASKWAIT**

*OpenMP* Fortran Compiler Directive: Specifies a wait on the completion of child tasks generated since the beginning of the current task.

**Syntax**

```fortran
!$OMP TASKWAIT
```
The TASKWAIT region includes an implicit task scheduling point in the current task region. The current task region is suspended at the task scheduling point until execution of all its child tasks generated before the TASKWAIT region are completed.

See Also
- T to Z
- OpenMP Fortran Compiler Directives
- TASK directive

THREADPRIVATE

OpenMP* Fortran Compiler Directive: Specifies named common blocks to be private (local) to a thread; they are global within the thread.

Syntax

```
c$OMP THREADPRIVATE (/ cb/ [, / cb/]...)
c
```

Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

```
$c

Is the name of the common block you want made private to a thread. Only named common blocks can be made thread private. Note that the slashes (/) are required.

Each thread gets its own copy of the common block, so data written to the common block by one thread is not directly visible to other threads.

During serial portions and MASTER sections of the program, accesses are to the master thread copy of the common block. On entry to the first parallel region, data in the THREADPRIVATE common blocks should be assumed to be undefined unless a COPYIN clause is specified in the PARALLEL directive.

When a common block (which is initialized using DATA statements) appears in a THREADPRIVATE directive, each thread copy is initialized once prior to its first use. For subsequent parallel regions, data in THREADPRIVATE common blocks are guaranteed to persist only if the dynamic threads mechanism has been disabled and if the number of threads are the same for all the parallel regions.
A THREADPRIVATE common block or its constituent variables can appear only in a COPYIN clause. They are not permitted in a PRIVATE, FIRSTPRIVATE, LASTPRIVATE, SHARED, or REDUCTION clause. They are not affected by the DEFAULT clause.

Example
In the following example, the common blocks BLK1 and FIELDS are specified as thread private:

```fortran
COMMON /BLK/ SCRATCH
COMMON /FIELDS/ XFIELD, YFIELD, ZFIELD
C$OMP THREADPRIVATE(/BLK/,/FIELDS/)
C$OMP PARALLEL DEFAULT(PRIVATE) COPYIN(/BLK1/,ZFIELD)
```

See Also
- T to Z
- OpenMP Fortran Compiler Directives

TIME Intrinsic Procedure

**Intrinsic Subroutine (Generic):** Returns the current time as set within the system. TIME can be used as an intrinsic subroutine or as a portability function or subroutine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL TIME (buf)
```

*buf*  
(Output) Is a variable, array, or array element of any data type, or a character substring. It must contain at least eight bytes of storage.

The date is returned as a 8-byte ASCII character string taking the form `hh:mm:ss`, where:

*hh*    
is the 2-digit hour  

*mm*    
is the 2-digit minute  

*ss*    
is the 2-digit second  

If *buf* is of numeric type and smaller than 8 bytes, data corruption can occur.
If `buf` is of character type, its associated length is passed to the subroutine. If `buf` is smaller than 8 bytes, the subroutine truncates the date to fit in the specified length. If an array of type character is passed, the subroutine stores the date in the first array element, using the element length, not the length of the entire array.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS LIB

Example

```fortran
CHARACTER*1 HOUR(8)
...
CALL TIME (HOUR)
```

The length of the first array element in CHARACTER array HOUR is passed to the TIME subroutine. The subroutine then truncates the time to fit into the 1-character element, producing an incorrect result.

See Also

- T to Z
- DATE_AND_TIME
- TIME portability routine

TIME Portability Routine

*Portability Function or Subroutine:* The function returns the system time, in seconds, since 00:00:00 Greenwich mean time, January 1, 1970. TIME can be used as an intrinsic subroutine or as a portability function or subroutine. It is an intrinsic procedure unless you specify USE IFPORT.

Module

USE IFPORT

Syntax

**Function Syntax:**

```fortran
result = TIME( )
```
Subroutine Syntax:

CALL TIME (timestr)

(Output) Character*(*) - Is the current time, based on a 24-hour clock, in the form hh:mm:ss, where hh, mm, and ss are two-digit representations of the current hour, minutes past the hour, and seconds past the minute, respectively.

Results

The result type is INTEGER(4). The result value is the number of seconds that have elapsed since 00:00:00 Greenwich mean time, January 1, 1970.

The subroutine fills a parameter with the current time as a string in the format hh:mm:ss. The value returned by this routine can be used as input to other portability date and time functions.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
INTEGER(4) int_time
character*8 char_time
int_time = TIME( )
call TIME(char_time)
print *, 'Integer: ', int_time, 'time: ', char_time
END

See Also

• T to Z
• DATE_AND_TIME
• TIME intrinsic procedure
**TIMEF**

**Portability Function:** Returns the number of seconds since the first time it is called, or zero.

**Module**

USE IFPORT

**Syntax**

\[ \text{result} = \text{TIMEF}( ) \]

**Results**

The result type is REAL(4). The result value is the number of seconds that have elapsed since the first time TIMEF was called.

The first time it is called, TIMEF returns 0.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

USE IFPORT

INTEGER i, j

REAL(8) elapsed_time

elapsed_time = TIMEF( )

DO i = 1, 100000
    j = j + 1
END DO

elapsed_time = TIMEF( )

PRINT *, elapsed_time
END

**See Also**

- T to Z
- Date and Time Procedures
**TINY**

*Inquiry Intrinsic Function (Generic):* Returns the smallest number in the model representing the same type and kind parameters as the argument.

**Syntax**

\[
\text{result} = \text{TINY}(x)
\]

\(x\) (Input) Must be of type real; it can be scalar or array valued.

**Results**

The result is a scalar with the same type and kind parameters as \(x\). The result has the value \(b^{-e_{\text{min}}-1}\). Parameters \(b\) and \(e_{\text{min}}\) are defined in [Model for Real Data](#).

**Example**

If \(X\) is of type REAL(4), TINY \((X)\) has the value \(2^{-126}\).

The following shows another example:

```fortran
REAL(8) r, result
r = 487923.3D0
result = TINY(r)  ! returns 2.225073858507201E-308
```

**See Also**

- T to Z
- HUGE
- Data Representation Models

**TRACEBACKQQ**

*Run-Time Subroutine:* Provides traceback information. Uses the Intel® Fortran run-time library traceback facility to generate a stack trace showing the program call stack as it appeared at the time of the call to TRACEBACKQQ().

**Module**

USE IFCORE
Syntax

CALL TRACEBACKQQ ([string] [,user_exit_code] [,status] [,eptr])

string
(Input; optional) CHARACTER(*). A message string to precede the traceback output. It is recommended that the string be no more than 80 characters (one line) since that length appears better on output. However, this limit is not a restriction and it is not enforced. The string is output exactly as specified; no formatting or interpretation is done.

If this argument is omitted, no header message string is produced.

user_exit_code
(Input; optional) INTEGER(4). An exit code. Two values are predefined:

• A value of -1 causes the run-time system to return execution to the caller after producing traceback.

• A value of zero (the default) causes the application to abort execution.

Any other specified value causes the application to abort execution and return the specified value to the operating system.

status
(Input; optional) INTEGER(4). A status value. If specified, the run-time system returns the status value to the caller indicating that the traceback process was successful. The default is not to return status.

Note that a returned status value is only an indication that the "attempt" to trace the call stack was completed successfully, not that it produced a useful result.

You can include the file iosdef.for in your program to obtain symbolic definitions for the possible return values. A return value of FOR$IOS_SUCCESS (0) indicates success.

eptr
(Input; optional) Integer pointer. It is required if calling from a user-specified exception filter. If omitted, the default in null.

To trace the stack after an exception has occurred, the runtime support needs access to the exception information supplied to the filter by the operating system.

The eptr argument is a pointer to a T_EXCEPTION_POINTERS structure, which is defined in ifcore.f90. This argument is optional and is usually omitted. On Windows systems,
T_EXCEPTION_POINTERS is returned by the Windows* API GetExceptionInformation( ), which is usually passed to a C try/except filter function.

The TRACEBACKQQ routine provides a standard way for an application to initiate a stack trace. It can be used to report application detected errors, debugging, and so forth. It uses the stack trace support in the Intel Fortran run-time library, and produces the same output that the run-time library produces for unhandled errors and exceptions.

The error message string normally included by the run-time system is replaced with the user-supplied message text, or omitted if no string is specified. Traceback output is directed to the target destination appropriate for the application type, just as it is when traceback is initiated internally by the run-time system.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**Example**

The following example generates a traceback report with no leading header message, from wherever the call site is, and aborts execution:

```fortran
USE IFCORE
CALL TRACEBACKQQ( )
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution:

```fortran
USE IFCORE
CALL TRACEBACKQQ("My application message string")
```

The following example generates a traceback report with the user-supplied string as the header, and aborts execution, returning a status code of 123 to the operating system:

```fortran
USE IFCORE
CALL TRACEBACKQQ(STRING="Bad value for TEMP",USER_EXIT_CODE=123)
```
Consider the following:

```fortran
... 
USE IFCORE 
INTEGER(4) RTN_STS 
INCLUDE 'IOSDEF.FOR' 
... 
CALL TRACEBACKQQ(USER_EXIT_CODE=-1,STATUS=RTN_STS) 
IF (RTN_STS .EQ. FOR$IOS_SUCCESS) THEN 
   PRINT *, 'TRACEBACK WAS SUCCESSFUL' 
END IF 
... 
```

This example generates a traceback report with no header string, and returns to the caller to continue execution of the application. If the traceback process succeeds, a status will be returned in variable RTN_STS.

For more examples, including one showing an integer pointer, see Building Applications: Obtaining Traceback Information with TRACEBACKQQ.

**See Also**
- T to Z
- GETEXCEPTIONPTRSQQ

Building Applications: Using Traceback Information
Building Applications: Run-Time Message Display and Format
Building Applications: Obtaining Traceback Information with TRACEBACKQQ

**TRAILZ**

*Elemental Intrinsic Function (Generic):*

> Returns the number of trailing zero bits in an integer.

**Syntax**

```fortran
result = TRAILZ (i) 
```

`i` (Input) Must be of type integer or logical.
Results
The result type is the same as \( i \). The result value is the number of trailing zeros in the binary representation of the integer \( i \).

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

Example
Consider the following:

```fortran
INTEGER*8 J, TWO
PARAMETER (TWO=2)
DO J = -1, 40
   TYPE *, TRAILZ(TWO**J) ! Prints 64, then 0 up to
ENDDO ! 40 (trailing zeros)
END
```

TRANSFER

Transformational Intrinsic Function (Generic):

Converts the bit pattern of the first argument according to the type and kind parameters of the second argument.

Syntax

\[
\text{result} = \text{TRANSFER} (\text{source}, \text{mold}[, \text{size}])
\]

- `source` (Input) Must be a scalar or array (of any data type).
- `mold` (Input) Must be a scalar or array (of any data type). It provides the type characteristics (not a value) for the result.
- `size` (Input; optional) Must be scalar and of type integer. It provides the number of elements for the output result.

Results

The result has the same type and type parameters as `mold`. If `mold` is a scalar and `size` is omitted, the result is a scalar.
If `mold` is an array and `size` is omitted, the result is a rank-one array. Its size is the smallest that is possible to hold all of `source`.

If `size` is present, the result is a rank-one array of size `size`.

If the physical representation of the result is larger than `source`, the result contains `source`'s bit pattern in its right-most bits; the left-most bits of the result are undefined.

If the physical representation of the result is smaller than `source`, the result contains the right-most bits of `source`'s bit pattern.

**Example**

TRANSFER (1082130432, 0.0) has the value 4.0 (on processors that represent the values 4.0 and 1082130432 as the string of binary digits 0100 0000 1000 0000 0000 0000 0000 0000).

TRANSFER ((/2.2, 3.3, 4.4/), ((0.0, 0.0))) results in a scalar whose value is (2.2, 3.3).

TRANSFER ((/2.2, 3.3, 4.4/), (/0.0, 0.0/)) results in a complex rank-one array of length 2. Its first element is (2.2, 3.3) and its second element has a real part with the value 4.4 and an undefined imaginary part.

TRANSFER ((/2.2, 3.3, 4.4/), (/0.0, 0.0/), 1) results in a complex rank-one array having one element with the value (2.2, 3.3).

The following shows another example:

```fortran
COMPLEX CVVECTOR(2), CX(1)
! The next statement sets CVVECTOR to
! [ 1.1 + 2.2i, 3.3 + 0.0i ]
CVVECTOR = TRANSFER((/1.1, 2.2, 3.3, 0.0/), 
                       (/0.0, 0.0/))
! The next statement sets CX to [ 1.1 + 2.2i ]
CX = TRANSFER((/1.1, 2.2, 3.3/), (/0.0, 0.0/), 
              SIZE= 1)
WRITE(*,*) CVVECTOR
WRITE(*,*) CX
END
```
TRANSPOSE
Transformational Intrinsic Function (Generic):
Transposes an array of rank two.

Syntax

\[
\text{result} = \text{TRANSPOSE} (\text{matrix})
\]

\text{matrix} \quad \text{(Input)} \text{Must be a rank-two array. It may be of any data type.}

Results

The result is a rank-two array with the same type and kind parameters as \text{matrix}. Its shape is \((n, m)\), where \((m, n)\) is the shape of \text{matrix}. For example, if the shape of \text{matrix} is \((4,6)\), the shape of the result is \((6,4)\).

Element \((i, j)\) of the result has the value \text{matrix}(j, i), where \(i\) is in the range 1 to \(n\), and \(j\) is in the range 1 to \(m\).

Example

\(B\) is the array

\[
\begin{bmatrix}
2 & 3 & 4 \\
5 & 6 & 7 \\
8 & 9 & 1
\end{bmatrix}
\]

\text{TRANSPOSE} (\(B\)) has the value

\[
\begin{bmatrix}
2 & 5 & 8 \\
3 & 6 & 9 \\
4 & 7 & 1
\end{bmatrix}
\]
The following shows another example:

```
INTEGER array(2, 3), result(3, 2)
array = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
! array is 1 3 5
! 2 4 6
result = TRANSPOSE(array)
! result is 1 2
! 3 4
! 5 6
END
```

See Also
• T to Z
• RESHAPE
• PRODUCT

TRIM

*Transformational Intrinsic Function (Generic):*

*Returns the argument with trailing blanks removed.*

**Syntax**

```
result = TRIM(string)
```

`string` (Input) Must be a scalar of type character.

**Results**

The result is of type character with the same kind parameter as `string`. Its length is the length of `string` minus the number of trailing blanks in `string`.

The value of the result is the same as `string`, except any trailing blanks are removed. If `string` contains only blank characters, the result has zero length.

**Example**

TRIM ("NAME") has the value 'NAME'.

TRIM ("C D") has the value 'C D'.
The following shows another example:

```fortran
! next line prints 28
WRITE(*,*) LEN("I have blanks behind me ")
! the next line prints 23
WRITE(*,*) LEN(TRIM("I have blanks behind me "))
END
```

See Also
- T to Z
- LEN_TRIM

TTYNAM

**Portability Subroutine:** Specifies a terminal device name.

**Module**

USE IFPORT

**Syntax**

CALL TTYNAM (string, lunit)

- **string**
  - (Output) Character*(*). Name of the terminal device. If the Fortran logical unit is not connected to a terminal, it returns a string filled with blanks.

- **lunit**
  - (Input) INTEGER(4). A Fortran logical unit number.

**Compatibility**

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

**TYPE Statement (Derived Types)**

**Statement:** Declares a variable to be a derived type. It specifies the name of the user-defined type and the types of its components.

**Syntax**

```fortran
TYPE [ [, type-attr-spec-list ] :: ] name
```
component-definition

[component-definition] . . .

END TYPE [ name ]

type-attr-spec-list  Is access-spec or BIND (C).

access-spec  Is the PUBLIC or PRIVATE keyword. The keyword can only be specified if the derived-type definition is in the specification part of a module.

name  Is the name of the derived data type. It must not be the same as the name of any intrinsic type, or the same as the name of a derived type that can be accessed from a module.

component-definition  Is one or more type declaration statements defining the component of derived type.

The first component definition can be preceded by an optional PRIVATE or SEQUENCE statement. (Only one PRIVATE or SEQUENCE statement can appear in a given derived-type definition.)

If SEQUENCE is present, all derived types specified in component definitions must be sequence types.

A component definition takes the following form:

type[,attr][: ]component[(a-spec)][*char-len][init-ex]

type  Is a type specifier. It can be an intrinsic type or a previously defined derived type. (If the POINTER attribute follows this specifier, the type can also be any accessible derived type, including the type being defined.)

attr  Is an optional POINTER attribute for a pointer component, or an optional DIMENSION or ALLOCATABLE attribute for an array component. You cannot specify both the ALLOCATABLE and POINTER attribute. If DIMENSION is specified, it can be followed by an array specification. Each attribute can only appear once in a given component-definition.

component  Is the name of the component being defined.
Is an optional array specification, enclosed in parentheses. If POINTER or ALLOCATABLE is specified, the array is deferred shape; otherwise, it is explicit shape. In an explicit-shape specification, each bound must be a constant scalar integer expression. If the array bounds are not specified here, they must be specified following the DIMENSION attribute.

Is an optional scalar integer literal constant; it must be preceded by an asterisk (*). This parameter can only be specified if the component is of type CHARACTER.

Is an initialization expression, or for pointer components, => NULL( ). This is a Fortran 95 feature. If init-ex is specified, a double colon must appear in the component definition. The equals assignment symbol (=) can only be specified for nonpointer components. The initialization expression is evaluated in the scoping unit of the type definition.

**Description**

If a name is specified following the END TYPE statement, it must be the same name that follows TYPE in the derived type statement.

A derived type can be defined only once in a scoping unit. If the same derived-type name appears in a derived-type definition in another scoping unit, it is treated independently.

A component name has the scope of the derived-type definition only. Therefore, the same name can be used in another derived-type definition in the same scoping unit.

Two data entities have the same type if they are both declared to be of the same derived type (the derived-type definition can be accessed from a module or a host scoping unit).

If the entities are in different scoping units, they can also have the same derived type if they are declared with reference to different derived-type definitions, and if both derived-type definitions have all of the following:

- The same name
• A SEQUENCE statement (they both have sequence type)
• Components that agree in name, order, and attributes; components cannot be private

If BIND (C) is specified, the following rules apply:
• The derived type cannot be a SEQUENCE type.
• The derived type must have type parameters.
• Each component of the derived type must be a nonpointer, nonallocatable data component with interoperable type and type parameters.

Example

! DERIVED.F90
! Define a derived-type structure,
! type variables, and assign values
TYPE member
    INTEGER age
    CHARACTER (LEN = 20) name
END TYPE member
TYPE (member) :: george
TYPE (member) :: ernie
george = member(33, 'George Brown')
ernie%age = 56
ernie%name = 'Ernie Brown'
WRITE (*,*) george
WRITE (*,*) ernie
END
The following shows another example of a derived type:

```fortran
TYPE mem_name
  SEQUENCE
  CHARACTER (LEN = 20) lastn
  CHARACTER (LEN = 20) firstn
  CHARACTER (len = 3) cos ! this works because COS is a component name
END TYPE mem_name

TYPE member
  TYPE (mem_name) :: name
  SEQUENCE
  INTEGER age
  CHARACTER (LEN = 20) specialty
END TYPE member

In the following example, a and b are both variable arrays of derived type pair:

```fortran
TYPE (pair)
  INTEGER i, j
END TYPE

TYPE (pair), DIMENSION (2, 2) :: a, b(3)
```
The following example shows how you can use derived-type objects as components of other derived-type objects:

```fortran
TYPE employee_name
  CHARACTER(25) last_name
  CHARACTER(15) first_name
END TYPE

TYPE employee_addr
  CHARACTER(20) street_name
  INTEGER(2) street_number
  INTEGER(2) apt_number
  CHARACTER(20) city
  CHARACTER(2) state
  INTEGER(4) zip
END TYPE

Objects of these derived types can then be used within a third derived-type specification, such as:

```fortran
TYPE employee_data
  TYPE (employee_name) :: name
  TYPE (employee_addr) :: addr
  INTEGER(4) telephone
  INTEGER(2) date_of_birth
  INTEGER(2) date_of_hire
  INTEGER(2) social_security(3)
  LOGICAL(2) married
  INTEGER(2) dependents
END TYPE
```

Type Declarations

**Statement:** Explicitly specifies the properties of data objects or functions.

**Syntax**

A type declaration statement has the general form:

```
    type[ [, att] ... :: ] v[/c-list/][, v[/c-list/]] ...
```

- **type**
  - Is one of the following data type specifiers:
    - BYTE
    - INTEGER[[KIND=k]]
    - REAL[[KIND=k]]
    - DOUBLE PRECISION
    - COMPLEX[[KIND=k]]
    - DOUBLE COMPLEX
    - CHARACTER[[KIND=k]]
    - LOGICAL[[KIND=k]]
    - TYPE (derived-type-name)

In the optional kind selector "([KIND=k])", \( k \) is the kind parameter.
It must be an acceptable kind parameter for that data type. If the kind selector is not present, entities declared are of default type.
Kind parameters for intrinsic numeric and logical data types can also be specified using the \*n format, where \( n \) is the length (in bytes) of the entity; for example, INTEGER*4. See each data type for further information on that type.

\textit{att} is one of the following attribute specifiers:

<table>
<thead>
<tr>
<th>Attribute Specifier</th>
<th>Alternative 1</th>
<th>Alternative 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATABLE</td>
<td>INTENT</td>
<td>PROTECTED</td>
</tr>
<tr>
<td>ASYNCHRONOUS</td>
<td>INTRINSIC</td>
<td>PUBLIC(^1)</td>
</tr>
<tr>
<td>AUTOMATIC</td>
<td>OPTIONAL</td>
<td>SAVE</td>
</tr>
<tr>
<td>BIND</td>
<td>PARAMETER</td>
<td>STATIC</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>POINTER</td>
<td>TARGET</td>
</tr>
<tr>
<td>EXTERNAL</td>
<td>PRIVATE(^1)</td>
<td>VOLATILE</td>
</tr>
</tbody>
</table>

\(^1\)These are access specifiers.

You can also declare any attribute separately as a statement. \textit{att} is the name of a data object or function. It can optionally be followed by:

- An array specification, if the object is an array.
  In a function declaration, an array must be a deferred-shape array if it has the POINTER attribute; otherwise, it must be an explicit-shape array.
- A character length, if the object is of type character.
- An initialization expression preceded by an = or, for pointer objects, => NULL( ).

A function name must be the name of an intrinsic function, external function, function dummy procedure, or statement function.

\textit{c-list} is a list of constants, as in a DATA statement. If \( v \) has the PARAMETER attribute, the \textit{c-list} cannot be present.
The \textit{c-list} cannot specify more than one value unless it initializes an array. When initializing an array, the \textit{c-list} must contain a value for every element in the array.

\textbf{Description}

Type declaration statements must precede all executable statements.

In most cases, a type declaration statement overrides (or confirms) the implicit type of an entity. However, a variable that appears in a DATA statement and is typed implicitly can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

The double colon separator (::) is required only if the declaration contains an attribute specifier or initialization; otherwise it is optional.

\textbf{If} \textit{att} \textbf{appears, \textit{c-list} cannot be specified; for example:}

\begin{verbatim}
 INTEGER I /2/ ! Valid
 INTEGER, SAVE :: I /2/ ! Invalid
\end{verbatim}

The same attribute must not appear more than once in a given type declaration statement, and an entity cannot be given the same attribute more than once in a scoping unit.

If the PARAMETER attribute is specified, the declaration must contain an initialization expression.

If \textit{=} \textbf{NULL( )} is specified for a pointer, its initial association status is disassociated.

A variable (or variable subobject) can only be initialized once in an executable program.

The INTENT, \textit{VALUE}, and OPTIONAL attributes can be specified only for dummy arguments.

\textbf{The \textit{VALUE} attribute must not be specified for a dummy procedure.}

If a declaration contains an initialization expression, but no PARAMETER attribute is specified, the object is a variable whose value is initially defined. The object becomes defined with the value determined from the initialization expression according to the rules of intrinsic assignment.

The presence of initialization implies that the name of the object is saved, except for objects in named common blocks or objects with the PARAMETER attribute.

The following objects cannot be initialized in a type declaration statement:

- A dummy argument
- A function result
- An object in a named common block (unless the type declaration is in a block data program unit)
- An object in blank common
- An allocatable array
- An external name
- An intrinsic name
- An automatic object
- An object that has the AUTOMATIC attribute

An object can have more than one attribute. The following table lists the compatible attributes:

**Table 929: Compatible Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Compatible with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATABLE</td>

</table>

1 With deferred shape

**Example**

The following show valid type declaration statements:

```plaintext
double precision b(6)
integer(kind=2) i
real(kind=4) x, y
real(4) x, y
logical, dimension(10,10) :: array_a, array_b
integer, parameter :: smallest = selected_real_kind(6, 70)
real(kind(0.0)) m
complex(kind=8) :: d
type(employee) :: manager
real, intrinsic :: cos
character(15) prompt
character*12, save :: hello_msg
integer count, matrix(4,4), sum
logical*2 switch
real :: x = 2.0
type (num), pointer :: first => null()
```
The following shows more examples:

REAL a (10)
LOGICAL, DIMENSION (5, 5) :: mask1, mask2
COMPLEX :: cube_root = (-0.5, 0.867)
INTEGER, PARAMETER :: short = SELECTED_INT_KIND (4)
REAL (KIND (0.0D0)) a1
REAL (KIND = 2) b
COMPLEX (KIND = KIND (0.0D0)) :: c
INTEGER (short) k ! Range at least -9999 to 9999
TYPE (member) :: george

**DEFINE and UNDEFINE**

*General Compiler Directives:* **DEFINE** creates a symbolic variable whose existence or value can be tested during conditional compilation. **UNDEFINE** removes a defined symbol.

**Syntax**

cDEC$ DEFINE name[ = val]
cDEC$ UNDEFINE name

c Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

name Is the name of the variable.

val INTEGER(4). The value assigned to name.

DEFINE creates and UNDEFINE removes symbols for use with the IF (or IF DEFINED) compiler directive. Symbols defined with DEFINE directive are local to the directive. They cannot be declared in the Fortran program.

Because Fortran programs cannot access the named variables, the names can duplicate Fortran keywords, intrinsic functions, or user-defined names without conflict.

To test whether a symbol has been defined, use the IF DEFINED (name) directive. You can assign an integer value to a defined symbol. To test the assigned value of name, use the IF directive. IF test expressions can contain most logical and arithmetic operators.

Attempting to undefine a symbol that has not been defined produces a compiler warning.

The DEFINE and UNDEFINE directives can appear anywhere in a program, enabling and disabling symbol definitions.

Example

!DEC$ DEFINE testflag
!DEC$ IF DEFINED (testflag)
   write (*,*) 'Compiling first line'
!DEC$ ELSE
   write (*,*) 'Compiling second line'
!DEC$ ENDIF
!DEC$ UNDEFINE testflag

Building Applications: Compiler Directives Related to Options
Building Applications: Using Predefined Preprocessor Symbols

UNION...END UNION

Statements: Define a data area that can be shared intermittently during program execution by one or more fields or groups of fields. A union declaration must be within a structure declaration.

Syntax

Each unique field or group of fields is defined by a separate map declaration.

UNION
  map-declaration
  map-declaration
  [map-declaration]
  ...
  [map-declaration]
END UNION

map-declaration Takes the following form:

MAP
  field-declaration
  [field-declaration]
  ...
  [field-declaration]
END MAP

field-declaration Is a structure declaration or RECORD statement contained within a union declaration, a union declaration contained within a union declaration, or the declaration of a data field (having a data type) within a union. It can be of any intrinsic or derived type.
As with normal Fortran type declarations, data can be initialized in field declaration statements in union declarations. However, if fields within multiple map declarations in a single union are initialized, the data declarations are initialized in the order in which the statements appear. As a result, only the final initialization takes effect and all of the preceding initializations are overwritten.

The size of the shared area established for a union declaration is the size of the largest map defined for that union. The size of a map is the sum of the sizes of the fields declared within it.

Manipulating data by using union declarations is similar to using EQUIVALENCE statements. The difference is that data entities specified within EQUIVALENCE statements are concurrently associated with a common storage location and the data residing there; with union declarations you can use one discrete storage location to alternately contain a variety of fields (arrays or variables).

With union declarations, only one map declaration within a union declaration can be associated at any point in time with the storage location that they share. Whenever a field within another map declaration in the same union declaration is referenced in your program, the fields in the prior map declaration become undefined and are succeeded by the fields in the map declaration containing the newly referenced field.

Example

In the following example, the structure WORDS_LONG is defined. This structure contains a union declaration defining two map fields. The first map field consists of three INTEGER*2 variables (WORD_0, WORD_1, and WORD_2), and the second, an INTEGER*4 variable, LONG:

```
STRUCTURE /WORDS_LONG/
  UNION
    MAP
      INTEGER*2 WORD_0, WORD_1, WORD_2
    END MAP
    MAP
      INTEGER*4 LONG
    END MAP
  END UNION
END STRUCTURE
```
The length of any record with the structure WORDS_LONG is 6 bytes. The following figure shows the memory mapping of any record with the structure WORDS_LONG:

**Figure 105: Memory Map of Structure WORDS_LONG**

In the following example, note how the first 40 characters in the string2 array are overlayed on 4-byte integers, while the remaining 20 are overlayed on 2-byte integers:

```fortran
UNION
  MAP
    CHARACTER*20 string1, CHARACTER*10 string2(6)
  END MAP
  MAP
    INTEGER*2 number(10), INTEGER*4 var(10), INTEGER*2 + datum(10)
  END MAP
END UNION
```

UNLINK

Portability Function: Deletes the file given by path.

Module
USE IFPORT

Syntax
result = UNLINK (name)

name (Input) Character*(*) Path of the file to delete. The path can use forward (/) or backward (\) slashes as path separators and can contain drive letters.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code. Errors can be one of the following:

• ENOENT: The specified file could not be found.
• EACCES: The specified file is read-only.

You must have adequate permission to delete the specified file.

On Windows systems, you will get the EACCES error if the file has been opened by any process.

Compatibility
CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB
Example

USE IFPORT
INTEGER(4) ISTATUS
CHARACTER*20 dirname
READ *, dirname
ISTATUS = UNLINK (dirname)
IF (ISTATUS) then
   print *, 'Error ', ISTATUS
END IF
END

See Also
- T to Z
- SYSTEM
- DELDIRQQ

UNPACK

Transformational Intrinsic Function (Generic):
Takes elements from a rank-one array and unpacks them into another (possibly larger) array under the control of a mask.

Syntax

result = UNPACK (vector, mask, field)

vector (Input) Must be a rank-one array. It may be of any data type. Its size must be at least \( t \), where \( t \) is the number of true elements in mask.

mask (Input) Must be a logical array. It determines where elements of vector are placed when they are unpacked.

field (Input) Must be of the same type and type parameters as vector and conformable with mask. Elements in field are inserted into the result array when the corresponding mask element has the value false.
Results

The result is an array with the same shape as \textit{mask}, and the same type and type parameters as \textit{vector}.

Elements in the result array are filled in array element order. If element \textit{i} of \textit{mask} is true, the corresponding element of the result is filled by the next element in \textit{vector}. Otherwise, it is filled by \textit{field} (if \textit{field} is scalar) or the \textit{i}th element of \textit{field} (if \textit{field} is an array).

Example

\texttt{N} is the array
\begin{verbatim}
[ 0 0 1 ]
[ 1 0 1 ]
[ 1 0 0 ],
\end{verbatim}
\texttt{P} is the array (2, 3, 4, 5), and \texttt{Q} is the array
\begin{verbatim}
[ T F F ]
[ F T F ]
[ T T F ].
\end{verbatim}
\texttt{UNPACK (P, MASK=Q, FIELD=N)} produces the result
\begin{verbatim}
[ 2 0 1 ]
[ 1 4 1 ]
[ 3 5 0 ].
\end{verbatim}
\texttt{UNPACK (P, MASK=Q, FIELD=1)} produces the result
\begin{verbatim}
[ 2 1 1 ]
[ 1 4 1 ]
[ 3 5 1 ].
\end{verbatim}
The following shows another example:

```
LOGICAL mask (2, 3)
INTEGER vector(3) /1, 2, 3/, AR1(2, 3)
mask = RESHAPE((/ .TRUE., .FALSE., .FALSE., .TRUE., &
                 .TRUE., .FALSE./), (/2, 3/))
! vector = [1 2 3] and mask = T F T
! F T F
AR1 = UNPACK(vector, mask, 8) ! returns 1 8 3
! 8 2 8
```

END

**See Also**
- T to Z
- PACK
- RESHAPE
- SHAPE

**UNPACKTIMEQQ**

*Portability Subroutine: Unpacks a packed time and date value into its component parts.*

**Module**

USE IFPORT

**Syntax**

```
CALL UNPACKTIMEQQ (timedate, iyr, imon, iday, ihr,imin, isec)
```

- `timedate` (Input) INTEGER(4). Packed time and date information.
- `iyr` (Output) INTEGER(2). Year (xxxxAD).
- `imon` (Output) INTEGER(2). Month (1 - 12).
- `iday` (Output) INTEGER(2). Day (1 - 31).
- `ihr` (Output) INTEGER(2). Hour (0 - 23).
- `imin` (Output) INTEGER(2). Minute (0 - 59).
- `isec` (Output) INTEGER(2). Second (0 - 59).
GETFILEINFOQQ returns time and date in a packed format. You can use UNPACKTIMEQQ to unpack these values. Use PACKTIMEQQ to repack times for passing to SETFILETIMEQQ. Packed times can be compared using relational operators.

Compatibility

CONSOLE STANDARD GRAPHICS QUICKWIN GRAPHICS WINDOWS DLL LIB

Example

USE IFPORT
CHARACTER(80) file
TYPE (FILEINFO) info
INTEGER(4) handle, result
INTEGER(2) iyr, imon, iday, ihr, imin, isec
file = 'd:\f90ps\bin\t???.*'  
handle = FILEFIRST
result = GETFILEINFOQQ(file, info, handle)
CALL UNPACKTIMEQQ(info%lastwrite, iyr, imon,&
    iday, ihr, imin, isec)

UNREGISTRERMOUSEEVENT (W^32, W^64)

QuickWin Function: Removes the callback routine registered for a specified window by an earlier call to REGISTERMOUSEEVENT.

Module

USE IFQWIN
Syntax

result = UNREGISTERMOUSEEVENT (unit, mouseevents)

unit  (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture and IA-64 architecture. Unit number of the window whose callback routine on mouse events is to be unregistered.

mouseevents (Input) INTEGER(4). One or more mouse events handled by the callback routine to be unregistered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:

- MOUSE$LBUTTONDOWN - Left mouse button down
- MOUSE$LBUTTONUP - Left mouse button up
- MOUSE$LBUTTONDBLCLK - Left mouse button double-click
- MOUSE$RBUTTONDOWN - Right mouse button down
- MOUSE$RBUTTONUP - Right mouse button up
- MOUSE$RBUTTONDBLCLK - Right mouse button double-click
- MOUSE$MOVE - Mouse moved

Results

The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer that can be one of the following:

- MOUSE$BADUNIT - The unit specified is not open, or is not associated with a QuickWin window.
- MOUSE$BADEVENT - The event specified is not supported.

Once you call UNREGISTERMOUSEEVENT, QuickWin no longer calls the callback routine specified earlier for the window when mouse events occur. Calling UNREGISTERMOUSEEVENT when no callback routine is registered for the window has no effect.

Compatibility

QUICKWIN GRAPHICS LIB

See Also

- T to Z
- REGISTERMOUSEEVENT
UNROLL and NOUNROLL

**General Compiler Directive:** Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop. These directives can only be applied to iterative DO loops.

**Syntax**

\[ \text{cDEC$ UNROLL [(n)] -or- cDEC$ UNROLL [=n]} \]
\[ \text{cDEC$ NOUNROLL} \]

\( c \)
- Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

\( n \)
- Is an integer constant. The range of \( n \) is 0 through 255.

If \( n \) is specified, the optimizer unrolls the loop \( n \) times. If \( n \) is omitted, or if it is outside the allowed range, the optimizer picks the number of times to unroll the loop.

The UNROLL directive overrides any setting of loop unrolling from the command line.

To use these directives, compiler option O2 or O3 must be set.

**Example**

\[ \text{cDEC$ UNROLL} \]
\[ \text{do i =1, m} \]
\[ \text{b(i) = a(i) + 1} \]
\[ \text{d(i) = c(i) + 1} \]
\[ \text{enddo} \]

**See Also**

- M to N
- T to Z
- General Compiler Directives
- Rules for General Directives that Affect DO Loops
- O compiler option
UNROLL_AND_JAM and NOUNROLL_AND_JAM

General Compiler Directive: Enables or disables loop unrolling and jamming. These directives can only be applied to iterative DO loops.

Syntax

\[
\text{cDEC$ \text{UNROLL\_AND\_JAM} \ [(n)] -or- cDEC$ \text{UNROLL\_AND\_JAM} \ [=n]}
\]
\[
\text{cDEC$ \text{NOUNROLL\_AND\_JAM}}
\]

\(c\) Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

\(n\) Is an integer constant. The range of \(n\) is 0 through 255.

Description

If \(n\) is specified, the optimizer unrolls the loop \(n\) times. If \(n\) is omitted, or if it is outside the allowed range, the optimizer picks the number of times to unroll the loop. The loops are partially unrolled and then the resulting loops are fused ("jammed") back together.

The UNROLL_AND_JAM directive overrides any setting of loop unrolling from the command line. It takes precedence over all other unrolling directives, including NOUNROLL.

To use these directives, compiler option O2 or O3 must be set.

Example

\[
\text{cDEC$ \text{UNROLL\_AND\_JAM = 4}}
\]
\[
\text{do i =1, m}
\]
\[
\quad b(i) = a(c(i)) + 1
\]
\[
\text{enddo}
\]

**USE**

**Statement:** Gives a program unit accessibility to public entities in a module.

**Syntax**

USE [[, mod-nature] ::] name [, rename-list]...

USE [[, mod-nature] ::] name, ONLY : [, only-list]

*mod-nature* Is INTRINSIC or NON_INTRINSIC. If INTRINSIC is used, *name* must be the name of an intrinsic module. If NON_INTRINSIC is used, *name* must be the name of a nonintrinsic module. If *mod-nature* is not specified, *name* must be the name of an intrinsic or nonintrinsic module. If both are provided, the nonintrinsic module is used. It is an error to specify a user module and an intrinsic module of the same name in the same program unit (see Examples).

*name* Is the name of the module.

*rename-list* Is one or more items having the following form:

- *local-name* => *mod-name*

  *local-name* Is the name of the entity in the program unit using the module or is "OPERATOR (op-name)", where *op-name* is the name of a defined operator in the program unit using the module.

  *mod-name* Is the name of a public entity in the module or is "OPERATOR (op-name)", where *op-name* is the name of a public entity in the module.

*only-list* Is the name of a public entity in the module or a generic identifier (a generic name, a defined operator specified as "OPERATOR (op-name)", or defined assignment).

An entity in the *only-list* can also take the form:

- [local-name =>] *mod-name*

**Description**

If the USE statement is specified without the ONLY option, the program unit has access to all public entities in the named module.
If the USE statement is specified with the ONLY option, the program unit has access to only those entities following the option.

If more than one USE statement for a given module appears in a scoping unit, the following rules apply:

- If one USE statement does not have the ONLY option, all public entities in the module are accessible, and any rename-lists and only-lists are interpreted as a single, concatenated rename-list.

- If all the USE statements have ONLY options, all the only-lists are interpreted as a single, concatenated only-list. Only those entities named in one or more of the only-lists are accessible.

If two or more generic interfaces that are accessible in a scoping unit have the same name, the same operator, or are both assignments, they are interpreted as a single generic interface. Otherwise, multiple accessible entities can have the same name only if no reference to the name is made in the scoping unit.

The local names of entities made accessible by a USE statement must not be respecified with any attribute other than PUBLIC or PRIVATE. The local names can appear in namelist group lists, but not in a COMMON or EQUIVALENCE statement.
The following shows examples of the USE statement:

```fortran
MODULE MOD_A
    INTEGER :: B, C
    REAL E(25, 5), D(100)
END MODULE MOD_A
...

SUBROUTINE SUB_Y
    USE MOD_A, DX => D, EX => E ! Array D has been renamed DX and array E
    ... ! has been renamed EX. Scalar variables B
    END SUBROUTINE SUB_Y ! and C are also available to this subroutine (using their module names).

SUBROUTINE SUB_Z
    USE MOD_A, ONLY: B, C ! Only scalar variables B and C are
    ... ! available to this subroutine
END SUBROUTINE SUB_Z
...
```

You must not specify a user module and an intrinsic module of the same name in the same program unit. For example, if you specify a user module named ISO_FORTRAN_ENV, then it is illegal to specify the following in the same program unit:

```fortran
USE :: ISO_FORTRAN_ENV
USE, INTRINSIC :: ISO_FORTRAN_ENV
```
The following example shows a module containing common blocks:

```fortran
MODULE COLORS
  COMMON /BLOCKA/ C, D(15)
  COMMON /BLOCKB/ E, F
  ...
END MODULE COLORS
...
FUNCTION HUE(A, B)
  USE COLORS
  ...
END FUNCTION HUE

The USE statement makes all of the variables in the common blocks in module COLORS available to the function HUE.
To provide data abstraction, a user-defined data type and operations to be performed on values of this type can be packaged together in a module. The following example shows such a module:

```fortran
MODULE CALCULATION
  TYPE ITEM
    REAL :: X, Y
  END TYPE ITEM
  INTERFACE OPERATOR (+)
    MODULE PROCEDURE ITEM_CALC
  END INTERFACE
  CONTAINS
    FUNCTION ITEM_CALC (A1, A2)
      TYPE(ITEM) A1, A2, ITEM_CALC
      ...
    END FUNCTION ITEM_CALC
    ...
  END MODULE CALCULATION

PROGRAM TOTALS
  USE CALCULATION
  TYPE(ITEM) X, Y, Z
  ...
  X = Y + Z
  ...
END
```

The USE statement allows program TOTALS access to both the type ITEM and the extended intrinsic operator + to perform calculations.
The following shows another example:

! Module containing original type declarations

MODULE geometry
  type square
    real side
    integer border
  end type
  type circle
    real radius
    integer border
  end type
END MODULE

! Program renames module types for local use.

PROGRAM test
  USE GEOMETRY,LSQUARE=>SQUARE,LCIRCLE=>CIRCLE
  ! Now use these types in declarations
  type (LSQUARE) s1,s2
  type (LCIRCLE) c1,c2,c3

The following shows a defined operator in a USE statement:

USE mymod, OPERATOR(.localop.) => OPERATOR(.moduleop.)

%VAL

Built-in Function: Changes the form of an actual argument. Passes the argument as an immediate value.

Syntax

%VAL (a)

a (Input) An expression, record name, procedure name, array, character array section, or array element.

Description

The argument is passed as follows:

- On IA-32 architecture, as a 32-bit immediate value. If the argument is integer (or logical) and shorter than 32 bits, it is sign-extended to a 32-bit value. For complex data types, %VAL passes two 32-bit arguments.
- On Intel® 64 architecture and IA-64 architecture, as a 64-bit immediate value. If the argument is integer (or logical) and shorter than 64 bits, it is sign-extended to a 64-bit value. For complex data types, %VAL passes two 64-bit arguments.

You must specify %VAL in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following tables list the Intel Fortran defaults for argument passing, and the allowed uses of %VAL:

Table 930: Expressions

<table>
<thead>
<tr>

<td>No</td>
</tr>
<tr>
<td>Aggregate ⁴</td>
<td>REF</td>
<td>No</td>
</tr>
<tr>
<td>Derived</td>
<td>REF</td>
<td>No</td>
</tr>
</tbody>
</table>

The %VAL and %REF functions override related cDEC$ ATTRIBUTE settings.

**Example**

```fortran
CALL SUB(2, %VAL(2))
```

Constant 2 is passed by reference. The second constant 2 is passed by immediate value.
1 If a logical or integer value occupies less than 64 bits of storage on Intel® 64 architecture and IA-64 architecture, or 32 bits of storage on IA-32 architecture, it is converted to the correct size by sign extension. Use the ZEXT intrinsic function if zero extension is desired.

2 i64 only

3 A character argument is passed by address and hidden length.

4 In Intel Fortran record structures

**See Also**
- T to Z
- CALL
- %REF
- %LOC

**VALUE**

**Statement and Attribute:** Specifies a type of argument association for a dummy argument.

**Syntax**

The VALUE attribute can be specified in a type declaration statement or a VALUE statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
type, [att-ls, ] VALUE [att-ls,] :: arg [, arg] ...
```

**Statement:**

```fortran
VALUE [:] arg [, arg]...
```

- **type**
  - Is a data type specifier.
- **att-ls**
  - Is an optional list of attribute specifiers.
- **arg**
  - Is the name of a dummy argument.

**Description**

The VALUE attribute can be used in INTERFACE body or in a procedure. It can only be specified for dummy arguments. It cannot be specified for a dummy procedure.

When this attribute is specified, the effect is as if the actual argument is assigned to a temporary, and the temporary is the argument associated with the dummy argument. The actual mechanism by which this happens is determined by the processor.
When the VALUE attribute is used in a type declaration statement, any length type parameter values must be omitted or they must be specified by initialization expressions.

If the VALUE attribute is specified, you cannot specify a PARAMETER, EXTERNAL, POINTER, ALLOCATABLE, DIMENSION, VOLATILE, or INTENT (INOUT or OUT) attribute in the same scoping unit.

**Example**

The following example shows how the VALUE attribute can be applied in a type declaration statement.

```fortran
j = 3
call sub (j)
write (*,*) j ! Writes 3
contains
subroutine sub (i)
integer, value :: I
i = 4
write (*,*) i ! Writes 4
end subroutine sub
end
```

**VECTOR ALIGNED and VECTOR UNALIGNED**

*General Compiler Directive:* Specifies that all data is aligned or no data is aligned in a DO loop.

**Syntax**

- `cDEC$ VECTOR ALIGNED`
- `cDEC$ VECTOR UNALIGNED`
c

Is one of the following: C (or c), !, or * (See Syntax Rules for Compiler Directives.)

Description

These directives override efficiency heuristics in the optimizer. The qualifiers UNALIGNED and ALIGNED instruct the compiler to use, respectively, unaligned and aligned data movement instructions for all array references. This disables all the advanced alignment optimizations of the compiler, such as determining alignment properties from the program context or using dynamic loop peeling to make references aligned.

CAUTION. The directives VECTOR ALIGNED and VECTOR UNALIGNED should be used with care. Overriding the efficiency heuristics of the compiler should only be done if you are absolutely sure the vectorization will improve performance. Furthermore, instructing the compiler to implement all array references with aligned data movement instructions will cause a runtime exception if some of the access patterns are actually unaligned.

See Also

- T to Z
- T to Z
- Rules for General Directives that Affect DO Loops

VECTOR ALWAYS and NOVECTOR

General Compiler Directive: Enables or disables vectorization of a DO loop.

Syntax

c DEC$ VECTOR ALWAYS

c DEC$ NOVECTOR

c

Is one of the following: C (or c), !, or * (See Syntax Rules for Compiler Directives.)

The VECTOR ALWAYS and NOVECTOR directives override the default behavior of the compiler. The VECTOR ALWAYS directive also overrides efficiency heuristics of the vectorizer, but it only works if the loop can actually be vectorized. You should use the IVDEP directive to ignore assumed dependences.
CAUTION. The directive VECTOR ALWAYS should be used with care. Overriding the efficiency heuristics of the compiler should only be done if you are absolutely sure the vectorization will improve performance.

Example

The compiler normally does not vectorize DO loops that have a large number of non-unit stride references (compared to the number of unit stride references).

In the following example, vectorization would be disabled by default, but the directive overrides this behavior:

```fortran
!DEC$ VECTOR ALWAYS
    do i = 1, 100, 2
        ! two references with stride 2 follow
        a(i) = b(i)
    enddo
```

There may be cases where you want to explicitly avoid vectorization of a loop; for example, if vectorization would result in a performance regression rather than an improvement. In these cases, you can use the NOVECTOR directive to disable vectorization of the loop.

In the following example, vectorization would be performed by default, but the directive overrides this behavior:

```fortran
!DEC$ NOVECTOR
    do i = 1, 100
        a(i) = b(i) + c(i)
    enddo
```

See Also

- **M to N**
- **T to Z**
- **Rules for General Directives that Affect DO Loops**
VECTOR TEMPORAL and VECTOR NONTEMPORAL (i32, i64em)

General Compiler Directive: Controls how the "stores" of register contents to storage are performed (streaming versus non-streaming). These directives are only available on IA-32 architecture and Intel® 64 architecture.

Syntax

```c
DEC$ VECTOR TEMPORAL
DEC$ VECTOR NONTEMPORAL [(var[, var]...)]
```

- `\texttt{c}`
  - Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)
- `\texttt{val}`
  - Is an optional memory reference in the form of a variable name.

Description

VECTOR NONTEMPORAL directs the compiler to use non-temporal (that is, streaming) stores. VECTOR TEMPORAL directs the compiler to use temporal (that is, non-streaming) stores.

By default, the compiler automatically determines whether a streaming store should be used for each variable.

Streaming stores may cause significant performance improvements over non-streaming stores for large numbers on certain processors. However, the misuse of streaming stores can significantly degrade performance.

For more information on this directive, including an example, see Optimizing Applications: Vectorization Support.

See Also

- T to Z
- T to Z
- Rules for General Directives that Affect DO Loops
VECTOR TEMPORAL and VECTOR NONTEMPORAL (i32, i64em)

**General Compiler Directive:** Controls how the "stores" of register contents to storage are performed (streaming versus non-streaming). These directives are only available on IA-32 architecture and Intel® 64 architecture.

**Syntax**

```
cDEC$ VECTOR TEMPORAL
```

```
cDEC$ VECTOR NONTEMPORAL [(var[, var]...)]
```

- **c**
  - Is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

- **val**
  - Is an optional memory reference in the form of a variable name.

**Description**

VECTOR NONTEMPORAL directs the compiler to use non-temporal (that is, streaming) stores. VECTOR TEMPORAL directs the compiler to use temporal (that is, non-streaming) stores.

By default, the compiler automatically determines whether a streaming store should be used for each variable.

Streaming stores may cause significant performance improvements over non-streaming stores for large numbers on certain processors. However, the misuse of streaming stores can significantly degrade performance.

For more information on this directive, including an example, see *Optimizing Applications: Vectorization Support*.

**See Also**

- T to Z
- T to Z
- Rules for General Directives that Affect DO Loops
VECTOR ALIGNED and VECTOR UNALIGNED

**General Compiler Directive:** Specifies that all data is aligned or no data is aligned in a DO loop.

**Syntax**

```c
DEC$ VECTOR ALIGNED
DEC$ VECTOR UNALIGNED
```

\( c \) is one of the following: C (or c), !, or *. (See Syntax Rules for Compiler Directives.)

**Description**

These directives override efficiency heuristics in the optimizer. The qualifiers UNALIGNED and ALIGNED instruct the compiler to use, respectively, unaligned and aligned data movement instructions for all array references. This disables all the advanced alignment optimizations of the compiler, such as determining alignment properties from the program context or using dynamic loop peeling to make references aligned.

**CAUTION.** The directives VECTOR ALIGNED and VECTOR UNALIGNED should be used with care. Overriding the efficiency heuristics of the compiler should only be done if you are absolutely sure the vectorization will improve performance.

Furthermore, instructing the compiler to implement all array references with aligned data movement instructions will cause a runtime exception if some of the access patterns are actually unaligned.

**See Also**

- T to Z
- T to Z
- Rules for General Directives that Affect DO Loops
**VERIFY**

*Elemental Intrinsic Function (Generic):* Verifies that a set of characters contains all the characters in a string by identifying the first character in the string that is not in the set.

**Syntax**

```fortran
result = VERIFY (string, set [, back] [, kind])
```

- `string` (Input) Must be of type character.
- `set` (Input) Must be of type character with the same kind parameter as `string`.
- `back` (Input; optional) Must be of type logical.
- `kind` (Input; optional) Must be a scalar integer initialization expression.

**Results**

The result type is integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If `back` is omitted (or is present with the value false) and `string` has at least one character that is not in `set`, the value of the result is the position of the leftmost character of `string` that is not in `set`.

If `back` is present with the value true and `string` has at least one character that is not in `set`, the value of the result is the position of the rightmost character of `string` that is not in `set`.

If each character of `string` is in `set` or the length of `string` is zero, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

**Example**

VERIFY ('CDDDC', 'C') has the value 2.
VERIFY ('CDDDC', 'C', BACK=.TRUE.) has the value 4.
VERIFY ('CDDDC', 'CD') has the value zero.
The following shows another example:

```fortran
 INTEGER(4) position
 position = VERIFY ('banana', 'nbc')  ! returns 2
 position = VERIFY ('banana', 'nbc', BACK=.TRUE.)
       ! returns 6
 position = VERIFY ('banana', 'nbca')  ! returns 0
```

See Also
- T to Z
- SCAN

**VIRTUAL**

**Statement:** Has the same form and effect as the DIMENSION statement. It is included for compatibility with PDP-11 FORTRAN.

See Also
- T to Z
- DIMENSION

**VOLATILE**

**Statement and Attribute:** Specifies that the value of an object is entirely unpredictable, based on information local to the current program unit. It prevents objects from being optimized during compilation.

**Syntax**

The VOLATILE attribute can be specified in a type declaration statement or a VOLATILE statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
 type, [att-ls, ] VOLATILE [, att-ls] :: object[, object] ...
```

**Statement:**

```fortran
 VOLATILE [:] object[, object] ...
```

`type` Is a data type specifier.
att-ls
Is an optional list of attribute specifiers.

object
Is the name of an object, or the name of a common block enclosed in slashes.

A variable or COMMON block must be declared VOLATILE if it can be read or written in a way that is not visible to the compiler. For example:

- If an operating system feature is used to place a variable in shared memory (so that it can be accessed by other programs), the variable must be declared VOLATILE.
- If a variable is accessed or modified by a routine called by the operating system when an asynchronous event occurs, the variable must be declared VOLATILE.

If an array is declared VOLATILE, each element in the array becomes volatile. If a common block is declared VOLATILE, each variable in the common block becomes volatile.

If an object of derived type is declared VOLATILE, its components become volatile.

If a pointer is declared VOLATILE, the pointer itself becomes volatile.

A VOLATILE statement cannot specify the following:

- A procedure
- A namelist group

Example

The following example shows a type declaration statement specifying the VOLATILE attribute:

```fortran
INTEGER, VOLATILE :: D, E
```

The following example shows a VOLATILE statement:

```fortran
PROGRAM TEST
LOGICAL(KIND=1) IPI(4)
INTEGER(KIND=4) A, B, C, D, E, ILOOK
INTEGER(KIND=4) P1, P2, P3, P4
COMMON /BLK1/A, B, C
VOLATILE /BLK1/, D, E
EQUIVALENCE(ILOOK, IPI)
EQUIVALENCE(A, P1)
EQUIVALENCE(P1, P4)
```
The named common block, BLK1, and the variables D and E are volatile. Variables P1 and P4 become volatile because of the direct equivalence of P1 and the indirect equivalence of P4.

**See Also**
- T to Z
- Type Declarations
- Compatible attributes

*Optimizing Applications: Improving I/O Performance*

**WAIT**

*Statement:* Performs a wait operation for a specified pending asynchronous data transfer operation. It takes one of the following forms:

**Syntax**

```plaintext
WAIT([UNIT=]io-unit [, END=label] [, EOR=label] [, ERR=label] [, ID=id-var] [, IOSTAT=i-var])
```

**io-unit**

(Input) Is an external unit specifier.

**label**

(Input) Is the label of the branch target statement that receives control if an error occurs.

**id-var**

(Input) Is a scalar integer variable that is the identifier of a pending data transfer operation for the specified unit. If it is specified, a wait operation is performed for that pending operation. If it is omitted, wait operations are performed for all pending data transfers for the specified unit.

**i-var**

(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

A wait operation completes the processing of a pending data transfer operation. Each wait operation completes only a single data transfer operation, although a single statement may perform multiple wait operations.

The WAIT statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

The EOR= specifier only has effect if the pending data transfer operation is a nonadvancing read. The END= specifier only has effect if the pending data transfer operation is a READ.
Example
The following example shows how the WAIT statement can be applied.

```fortran
program test
  integer, asynchronous, dimension(100) :: array
  open (unit=1, file='asynch.dat', asynchronous='YES', &
       form='unformatted')
  write (1) (i, i=1, 100)
  rewind (1)
  read (1, asynchronous='YES') array
  wait(1)
  write (*,*) array(1:10)
end
```

**WAITONMOUSEEVENT (W*32, W*64)**

*QuickWin Function:* Waits for the specified mouse input from the user.

**Module**

```fortran
USE IFQWIN
```

**Syntax**

```fortran
result = WAITONMOUSEEVENT (mouseevents, keystate, x, y)
```

- **mouseevents** (Input) INTEGER(4). One or more mouse events that must occur before the function returns. Symbolic constants for the possible mouse events are:
  - MOUSE$LBUTTONDOWN - Left mouse button down
  - MOUSE$LBUTTONUP - Left mouse button up
  - MOUSE$LBUTTONDBLCLK - Left mouse button double-click
  - MOUSE$RBUTTONDOWN - Right mouse button down
  - MOUSE$RBUTTONUP - Right mouse button up
  - MOUSE$RBUTTONDBLCLK - Right mouse button double-click
MOUSE$MOVE - Mouse moved

keystate
(Output) INTEGER(4). Bitwise inclusive OR of the state of the mouse during the event. The value returned in keystate can be any or all of the following symbolic constants:

- MOUSE$KS_LBUTTON - Left mouse button down during event
- MOUSE$KS_RBUTTON - Right mouse button down during event
- MOUSE$KS_SHIFT - SHIFTkey held down during event
- MOUSE$KS_CONTROL - CTRLkey held down during event

x
(Output) INTEGER(4). X position of the mouse when the event occurred.

y
(Output) INTEGER(4). Y position of the mouse when the event occurred.

Results
The result type is INTEGER(4). The result is the symbolic constant associated with the mouse event that occurred if successful. If the function fails, it returns the constant MOUSE$BADEVENT, meaning the event specified is not supported.

WAITONMOUSEEVENT does not return until the specified mouse input is received from the user. While waiting for a mouse event to occur, the status bar changes to read "Mouse input pending in XXX", where XXX is the name of the window. When a mouse event occurs, the status bar returns to its previous value.

A mouse event must happen in the window that had focus when WAITONMOUSEEVENT was initially called. Mouse events in other windows will not end the wait. Mouse events in other windows cause callbacks to be called for the other windows, if callbacks were previously registered for those windows.

For every BUTTONDOWN or BUTTONDBLCLK event there is an associated BUTTONUP event. When the user double clicks, four events happen: BUTTONDOWN and BUTTONUP for the first click, and BUTTONDBLCLK and BUTTONUP for the second click. The difference between getting BUTTONDBLCLK and BUTTONDOWN for the second click depends on whether the second click occurs in the double click interval, set in the system's CONTROL PANEL/MOUSE.

Compatibility
QUICKWIN GRAPHICS LIB
**Example**

```fortran
USE IFQWIN

INTEGER(4) mouseevent, keystate, x, y, result
...

mouseevent = MOUSE$RBUTTONDOWN .OR. MOUSE$LBUTTONDOWN
result = WAITONMOUSEEVENT (mouseevent, keystate, x, y)

! Wait until right or left mouse button clicked, then check the keystate
! with the following:
!
if ((MOUSE$KS_SHIFT .AND. keystate) == MOUSE$KS_SHIFT) then &
   & write (*,*) 'Shift key was down'
if ((MOUSE$KS_CONTROL .AND. keystate) == MOUSE$KS_CONTROL) then &
   & write (*,*) 'Ctrl key was down'
```

**Building Applications: Blocking Procedures**

**WHERE**

*Statement and Construct*: Lets you use masked array assignment, which performs an array operation on selected elements. This kind of assignment applies a logical test to an array on an element-by-element basis.

**Syntax**

*Statement:*

WHERE (mask-expr1) assign-stmt
Construct:

```plaintext
[name:]WHERE (mask-expr1)
    [where-body-stmt] ...
ELSE WHERE(mask-expr2) [name]
    [where-body-stmt] ...
ELSE WHERE[name]
    [where-body-stmt] ...
END WHERE [name]
```

*mask-expr1, mask-expr2* Are logical array expressions (called mask expressions).
*assign-stmt* Is an assignment statement of the form: array variable = array expression.
*name* Is the name of the WHERE construct.
*where-body-stmt* Is one of the following:

- An *assign-stmt*
  The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.
- A WHERE statement or construct

**Description**

If a construct *name* is specified in a WHERE statement, the same name must appear in the corresponding END WHERE statement. The same construct name can optionally appear in any ELSE WHERE statement in the construct. (ELSE WHERE cannot specify a different name.)

In each assignment statement, the mask expression, the variable being assigned to, and the expression on the right side, must all be conformable. Also, the assignment statement cannot be a defined assignment.

Only the WHERE statement (or the first line of the WHERE construct) can be labeled as a branch target statement.
The following shows an example using a WHERE statement:

```fortran
INTEGER A, B, C
DIMENSION A(5), B(5), C(5)
DATA A /0,1,1,1,0/
DATA B /10,11,12,13,14/
C = -1
WHERE(A .NE. 0) C = B / A
```

The assignment statement is only executed for those elements where the mask is true. Think of the mask expression as being evaluated first into a logical array that has the value true for those elements where A is positive. This array of trues and falses is applied to the arrays A, B and C in the assignment statement. The right side is only evaluated for elements for which the mask is true; assignment on the left side is only performed for those elements for which the mask is true. The elements for which the mask is false do not get assigned a value.

In a WHERE construct, the mask expression is evaluated first and only once. Every assignment statement following the WHERE is executed as if it were a WHERE statement with "mask-expr1" and every assignment statement following the ELSE WHERE is executed as if it were a WHERE statement with ".NOT. mask-expr1". If ELSE WHERE specifies "mask-expr2", it is executed as "(.NOT. mask-expr1) .AND. mask-expr2" during the processing of the ELSE WHERE statement.

You should be careful if the statements have side effects, or modify each other or the mask expression.

The following is an example of the WHERE construct:

```fortran
DIMENSION PRESSURE(1000), TEMP(1000), PRECIPITATION(1000)
WHERE(PRESSURE .GE. 1.0)
   PRESSURE = PRESSURE + 1.0
   TEMP = TEMP - 10.0
ELSEWHERE
   PRECIPITATION = .TRUE.
ENDWHERE
```
The mask is applied to the arguments of functions on the right side of the assignment if they are considered to be elemental functions. Only elemental intrinsics are considered elemental functions. Transformational intrinsics, inquiry intrinsics, and functions or operations defined in the subprogram are considered to be nonelemental functions.

Consider the following example using LOG, an elemental function:

```fortran
WHERE(A .GT. 0) B = LOG(A)
```

The mask is applied to A, and LOG is executed only for the positive values of A. The result of the LOG is assigned to those elements of B where the mask is true.

Consider the following example using SUM, a nonelemental function:

```fortran
REAL A, B
DIMENSION A(10,10), B(10)
WHERE(B .GT. 0.0) B = SUM(A, DIM=1)
```

Since SUM is nonelemental, it is evaluated fully for all of A. Then, the assignment only happens for those elements for which the mask evaluated to true.

Consider the following example:

```fortran
REAL A, B, C
DIMENSION A(10,10), B(10), C(10)
WHERE(C .GT. 0.0) B = SUM(LOG(A), DIM=1)/C
```

Because SUM is nonelemental, all of its arguments are evaluated fully regardless of whether they are elemental or not. In this example, LOG(A) is fully evaluated for all elements in A even though LOG is elemental. Notice that the mask is applied to the result of the SUM and to C to determine the right side. One way of thinking about this is that everything inside the argument list of a nonelemental function does not use the mask, everything outside does.

**Example**

```fortran
REAL(4) a(20)

. . .

WHERE (a > 0.0)
  a = LOG (a)
  !LOG is invoked only for positive elements
END WHERE
```
WORKSHARE

OpenMP® Fortran Compiler Directive: Divides the work of executing a block of statements or constructs into separate units. It also distributes the work of executing the units to threads of the team so each unit is only executed once.

Syntax

c$OMP WORKSHARE

        block

c$OMP END WORKSHARE[ NOWAIT]

c   Is one of the following: C (or c), !, or * (see Syntax Rules for Compiler Directives).

block   Is a structured block (section) of statements or constructs. No branching into or out of the block of code is allowed. The block is executed so that each statement is completed before the next statement is started and the evaluation of the right hand side of an assignment is completed before the effects of assigning to the left hand side occur.

The following are additional rules for this argument:

- block may contain statements which bind to lexically enclosed PARALLEL constructs. Statements in these PARALLEL constructs are not restricted.
- block may contain ATOMIC directives and CRITICAL constructs.
- block must only contain array assignment statements, scalar assignment statements, FORALL statements, FORALL constructs, WHERE statements, or WHERE constructs.
- block must not contain any user defined function calls unless the function is ELEMENTAL.
If you do not specify the NOWAIT keyword, synchronization is implied following the code.

**See Also**

- OpenMP Fortran Compiler Directives
- PARALLEL WORKSHARE

**WRAPON (W*32, W*64)**

*Graphics Function: Controls whether text output is wrapped.*

**Module**

USE IFQWIN

**Syntax**

result = WRAPON (option)

option (Input) INTEGER(2). Wrap mode. One of the following symbolic constants:
- $GWRAPOFF - Truncates lines at right edge of window border.
- $GWRAPON - Wraps lines at window border, scrolling if necessary.

**Results**

The result type is INTEGER(2). The result is the previous value of option.

WRAPON controls whether text output with the OUTTEXT function wraps to a new line or is truncated when the text output reaches the edge of the defined text window.

WRAPON does not affect font routines such as OUTGTEXT.

**Compatibility**

STANDARD GRAPHICS QUICKWIN GRAPHICS LIB

WRITE Statement
Statement: Transfers output data to external sequential, direct-access, or internal records.
Syntax
Sequential
Formatted:
Formatted · List-Directed:
Formatted · Namelist:
WRITE (eunit, nml-group [, asynchronous] [, id] [, pos] [, iostat] [, err])
Unformatted:

Direct-Access
Formatted:
WRITE (eunit, format, rec [, asynchronous] [, id] [, pos] [, iostat] [, err]) [io-list]

Unformatted:
WRITE (eunit, rec [, asynchronous] [, id] [, pos] [, iostat] [, err]) [io-list]

Internal
WRITE (iunit, format [, iostat] [, err]) [io-list]

eunit

Is an external unit specifier, optionally prefaced by UNIT=. UNIT= is required if eunit is not the first specifier in the list.

format

Is a format specifier. It is optionally prefaced by FMT= if format is the second specifier in the list and the first specifier indicates a logical or internal unit specifier without the optional keyword UNIT=.

advance

Is an advance specifier (ADVANCE=c-expr). If the value of c-expr is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.

asynchronous

Is an asynchronous specifier (ASYNCHRONOUS=i-expr). If the value of i-expr is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.

id

Is an id specifier (ID=id-var). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.

pos

Is a pos specifier (POS=p) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.
Is the name of a variable to contain the completion status of the I/O operation. Optionally prefaced by IOSTAT=.

Are branch specifiers if an error (ERR=label) condition occurs.

Is an I/O list: the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list.

Is the nonkeyword form of a format specifier (no FMT=).

Is the format specifier indicating list-directed formatting. (It can also be specified as FMT= *.)

Is the namelist group specification for namelist I/O. Optionally prefaced by NML=. NML= is required if nml-group is not the second I/O specifier. For more information, see Namelist Specifier.

Is the cell number of a record to be accessed directly. Optionally prefaced by REC=.

Is an internal unit specifier, optionally prefaced by UNIT=. UNIT= is required if iunit is not the first specifier in the list.

It must be a character variable. It must not be an array section with a vector subscript.

If an item in io-list is an expression that calls a function, that function must not execute an I/O statement or the EOF intrinsic function on the same external unit as eunit.

Example

! write to file
open(1,FILE='test.dat')
write (1, '(A20)') namedef
! write with FORMAT statement
WRITE (*, 10) (n, SQRT(FLOAT(n)), FLOAT(n)**(1.0/3.0), n = 1, 100)
10 FORMAT (I5, F8.4, F8.5)

The following shows another example:
WRITE(6,'("Expected ",F12.6")') 2.0

XOR
See Ieor.

ZEXT
Elemental Intrinsic Function (Generic):
Extends an argument with zeros. This function is used primarily for bit-oriented operations. It cannot be passed as an actual argument.

Syntax
result = ZEXT (x [,kind])

x (Input) Must be of type logical or integer.
kind (Input; optional) Must be a scalar integer initialization expression.

Results
The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value is x extended with zeros and treated as an unsigned value.

The storage requirements for integer constants are never less than two bytes. Integer constants within the range of constants that can be represented by a single byte still require two bytes of storage.

The setting of compiler options specifying integer size can affect this function.

1 These specific functions cannot be passed as actual arguments.
Example

Consider the following example:

```
INTEGER(2) W_VAR  /'FFFF'X/
INTEGER(4) L_VAR
L_VAR = ZEXT( W_VAR )
```

This example stores an INTEGER(2) quantity in the low-order 16 bits of an INTEGER(4) quantity, with the resulting value of L_VAR being '0000FFFF'X. If the ZEXT function had not been used, the resulting value would have been 'FFFFFFFF'X, because W_VAR would have been converted to the left-hand operand’s data type by sign extension.
### Glossary A

<tr>
<td>alphanumeric</td>
<td>Pertaining to letters and digits.</td>
</tr>
<tr>
<td>alternate return</td>
<td>A subroutine argument that permits control to branch immediately to some position other than the statement following the call. The actual argument in an alternate return is the statement label to which control should be transferred. (An alternate return is an obsolescent feature in Fortran 90.)</td>
</tr>
<tr>
<td>ANSI</td>
<td>The American National Standards Institute. An organization through which accredited organizations create and maintain voluntary industry standards.</td>
</tr>
<tr>
<td>argument</td>
<td>Can be either of the following:</td>
</tr>
<tr>
<td></td>
<td>- An actual argument--A variable, expression, or procedure passed from a calling program unit to a subprogram. See also actual argument.</td>
</tr>
</tbody>
</table>
• A dummy argument--A variable whose name appears in the parenthesized list following the procedure name in a FUNCTION statement, a SUBROUTINE statement, an ENTRY statement, or a statement function statement. See also dummy argument.

argument association
The relationship (or "matching up") between an actual argument and dummy argument during the execution of a procedure reference.

argument keyword
The name of a dummy (formal) argument. The name is used in a subprogram definition. Argument keywords can be used when the subprogram is invoked to associate dummy arguments with actual arguments, so that the subprogram arguments can appear in any order. Argument keywords are supplied for many of the intrinsic procedures.

array
A set of scalar data that all have the same type and kind type parameters. An array can be referenced by element (using a subscript), by section (using a section subscript list), or as a whole. An array has a rank (up to 7), bounds, size, and a shape.
An individual array element is a scalar object. An array section, which is itself an array, is a subset of the entire array. Contrast with scalar. See also bounds, conformable, shape, size, whole array, and zero-sized array.

array constructor
A mechanism used to specify a sequence of scalar values that produce a rank-one array. To construct an array of rank greater than one, you must apply the RESHAPE intrinsic function to the array constructor.

array element
A scalar (individual) item in an array. An array element is identified by the array name followed by one or more subscripts in parentheses, indicating the element's position in the array. For example, B(3) or A(2,5).

array pointer
A pointer to an array. See also array and pointer.

array section
A subobject (or portion) of an array. It consists of the set of array elements or substrings of this set. The set (or section subscript list) is specified by subscripts, subscript triplets, or vector subscripts. If the set does not contain at least one subscript triplet or vector subscript, the reference indicates an array element, not an array.

array specification
A program statement specifying an array name and the number of dimensions the array contains (its rank). An array specification can appear in a DIMENSION or COMMON statement, or in a type declaration statement.

ASCII
The American Standard Code for Information Interchange. A 7-bit character encoding scheme associating an integer from 0 through 127 with 128 characters.
**assignment statement** Usually, a statement that assigns (stores) the value of an expression on the right of an equal sign to the storage location of the variable to the left of the equal sign. In the case of Fortran 95/90 pointers, the storage location is assigned, not the pointer itself.

**association** The relationship that allows an entity to be referenced by different names in one scoping unit or by the same or different names in more than one scoping unit. The principal kinds of association are argument, host, pointer, storage, and use association. See also argument association, host association, pointer association, storage association, and use association.

**association status** Indicates whether or not a pointer is associated with a target. An association status is one of: undefined, associated, or disassociated. An undefined association status means a pointer can no longer be referenced, defined, or deallocated. An undefined pointer can, however, be allocated, nullified, or pointer assigned to a new target. See also allocation status.

**assumed-length character argument** A dummy argument that assumes the length attribute of the corresponding actual argument. An asterisk (*) specifies the length of the dummy character argument.

**assumed-shape array** A dummy argument array that assumes the shape of its associated actual argument array. The rank of the array is the number of colons (:) specified in parentheses.

**assumed-size array** A dummy array whose size (only) is assumed from its associated actual argument. The upper bound of its last dimension is specified by an asterisk (*). All other extents (if any) must be specified.

**attribute** A property of a data object that can be specified in a type declaration statement. These properties determine how the data object can be used in a program. Most attributes can be alternatively specified in statements. For example, the `DIMENSION` statement has the same meaning as the `DIMENSION` attribute appearing in a type declaration statement.

**automatic array** An explicit-shape array that is a local variable in a subprogram. It is not a dummy argument, and has bounds that are nonconstant specification expressions. The bounds (and shape) are determined at entry to the procedure by evaluating the bounds expressions. See also automatic object.

**automatic object** A local data object that is created upon entry to a subprogram and disappears when the execution of the subprogram is completed. There are two kinds of automatic objects: arrays (of any data type) and objects of type CHARACTER. Automatic objects cannot be saved or initialized.
An automatic object is not a dummy argument, but is declared with a specification expression that is not a constant expression. The specification expression can be the bounds of the array or the length of the character object.

**Glossary B**

**background process**  On Linux* systems, a process for which the command interpreter is not waiting. Its process group differs from that of its controlling terminal, so it is blocked from most terminal access. Contrast with *foreground process*.

**background window**  Any window created by a thread other than the foreground thread.

**big endian**  A method of data storage in which the least significant bit of a numeric value spanning multiple bytes is in the highest addressed byte. Contrast with *little endian*.

**binary constant**  A constant that is a string of binary (base 2) digits (0 or 1) enclosed by apostrophes or quotation marks and preceded by the letter B.

**binary operator**  An operator that acts on a pair of operands. The exponentiation, multiplication, division, and concatenation operators are binary operators.

**bit constant**  A constant that is a binary, octal, or hexadecimal number.

**bit field**  A contiguous group of bits within a binary pattern; they are specified by a starting bit position and length. Some intrinsic functions (for example, *IBSET* and *BTEST*) and the intrinsic subroutine *MVBITS* operate on bit fields.

**bitmap**  An array of bits that contains data that describes the colors found in a rectangular region on the screen (or the rectangular region found on a page of printer paper).

**blank common**  A common block (one or more contiguous areas of storage) without a name. Common blocks are defined by a *COMMON* statement.

**block**  In general, a group of related items treated as a physical unit. For example, a block can be a group of constructs or statements that perform a task; the task can be executed once, repeatedly, or not at all.

**block data program unit**  A program unit, containing a *BLOCK DATA* statement and its associated specification statements, that establishes common blocks and assigns initial values to the variables in named common blocks. In FORTRAN 77, this was called a block data subprogram.
bounds The range of subscript values for elements of an array. The lower bound is the smallest subscript value in a dimension, and the upper bound is the largest subscript value in that dimension. Array bounds can be positive, zero, or negative. These bounds are specified in an array specification. See also array specification.

breakpoint A critical point in a program, at which execution is stopped so that you can see if the program variables contain the correct values. Breakpoints are often used to debug programs.

brush A bitmap that is used to fill the interior of closed shapes, polygons, ellipses, and paths.

brush origin A coordinate that specifies the location of one of the pixels in a brush's bitmap. The Windows system maps this pixel to the upper left corner of the window that contains the object to be painted. See also bitmap.

built-in procedure See intrinsic procedure.

byte A group of 8 contiguous bits (binary digits) starting on an addressable boundary.

byte-order mark A special Unicode character (0xFEFF) that is placed at the beginning of Unicode text files to indicate that the text is in Unicode format.

Glossary C

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>carriage-control</td>
<td>A character in the first position of a printed record that determines the vertical spacing of the output line.</td>
</tr>
<tr>
<td>character constant</td>
<td>A constant that is a string of printable ASCII characters enclosed by apostrophes (‘) or quotation marks (&quot;).</td>
</tr>
<tr>
<td>character expression</td>
<td>A character constant, variable, function value, or another constant expression, separated by a concatenation operator (/); for example, DAY// 'FIRST'.</td>
</tr>
<tr>
<td>character storage unit</td>
<td>The unit of storage for holding a scalar value of default character type (and character length one) that is not a pointer. One character storage unit corresponds to one byte of memory.</td>
</tr>
<tr>

<td>A process initiated by another process (the parent). The child process can operate independently from the parent process. Also, the parent process can suspend or terminate without affecting the child process. See also parent process.</td>
</tr>
<tr>
<td>child window</td>
<td>A window that has the WS_CHILD style. A child window always appears within the client area of its parent window. See also parent window.</td>
</tr>
</tbody>
</table>
column-major order  See order of subscript progression.

comment  Text that documents or explains a program. In free source form, a comment begins with an exclamation point (!), unless it appears in a Hollerith or character constant.
In fixed and tab source form, a comment begins with a letter C or an asterisk (*) in column 1. A comment can also begin with an exclamation point anywhere in a source line (except in a Hollerith or character constant) or in column 6 of a fixed-format line. The comment extends from the exclamation point to the end of the line.
The compiler does not process comments, but shows them in program listings. See also compiler directive.

common block  A physical storage area shared by one or more program units. This storage area is defined by a COMMON statement. If the common block is given a name, it is a named common block; if it is not given a name, it is a blank common. See also blank common and named common block.

compilation unit  The source or files that are compiled together to form a single object file, possibly using interprocedural optimization across source files.

compiler directive  A structured comment that tells the compiler to perform certain tasks when it compiles a source program unit. Compiler directives are usually compiler-specific. (Some Fortran compilers call these directives "metacommands").

compiler option  An option (or flag) that can be used on the compiler command line to override the default behavior of the Intel® Fortran compiler.

complex constant  A constant that is a pair of real or integer constants representing a complex number; the pair is separated by a comma and enclosed in parentheses. The first constant represents the real part of the number; the second constant represents the imaginary part. The following types of complex constants are available on all systems: COMPLEX(KIND=4), COMPLEX(KIND=8), and COMPLEX(KIND=16).

complex type  A data type that represents the values of complex numbers. The value is expressed as a complex constant. See also data type.

component  Part of a derived-type definition. There must be at least one component (intrinsic or derived type) in every derived-type definition.

concatenate  The combination of two items into one by placing one of the items after the other. In Fortran 95/90, the concatenation operator (//) is used to combine character items. See also character expression.

conformable  Pertains to dimensionality. Two arrays are conformable if they have the same shape. A scalar is conformable with any array.

conformance  See shape conformance.
The inline expansion of small procedures, with conservative heuristics to limit extra code.

An interface that provides input and output to character-mode applications.

A data object whose value does not change during the execution of a program; the value is defined at the time of compilation. A constant can be named (using the PARAMETER attribute or statement) or unnamed. An unnamed constant is called a literal constant. The value of a constant can be numeric or logical, or it can be a character string. Contrast with variable.

An expression whose value does not change during program execution.

A series of statements starting with a DO, SELECT CASE, IF, FORALL, or WHERE statement, and ending with the appropriate termination statement.

Pertaining to entities that are adjacent (next to one another) without intervening blanks (spaces); for example, contiguous characters or contiguous areas of storage.

A format descriptor that directly displays text or affects the conversions performed by subsequent data edit descriptors. Except for the slash descriptor, control edit descriptors are nonrepeatable.

A statement that alters the normal order of execution by transferring control to another part of a program unit or a subprogram. A control statement can be conditional (such as the IF construct or computed GO TO statement) or unconditional (such as the STOP or GO TO statement).

An object used to synchronize the threads of a single process. Only one thread at a time can own a critical-section object.

**Glossary D**

A style of programming in which you define types to represent objects in your program, define a set of operations for objects of each type, and restrict the operations to only this set, making the types abstract. The Fortran 95/90 modules, derived types, and defined operators, support this programming paradigm.

A repeatable format descriptor that causes the transfer or conversion of data to or from its internal representation. In FORTRAN 77, this term was called a field descriptor.

A data object that has a data type. It is the result of the evaluation of an expression, or the result of the execution of a function reference (the function result).
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>data item</td>
<td>A unit of data (or value) to be processed. Includes constants, variables, arrays, character substrings, or records.</td>
</tr>
<tr>
<td>data object</td>
<td>A constant, variable, or subobject (part) of a constant or variable. Its type may be specified implicitly or explicitly.</td>
</tr>
<tr>
<td>data type</td>
<td>The properties and internal representation that characterize data and functions. Each intrinsic and user-defined data type has a name, a set of operators, a set of values, and a way to show these values in a program. The basic intrinsic data types are integer, real, complex, logical, and character. The data value of an intrinsic data type depends on the value of the type parameter. See also type parameter.</td>
</tr>
<tr>
<td>data type declaration</td>
<td>See type declaration statement.</td>
</tr>
<tr>
<td>data type length specifier</td>
<td>The form <em>n appended to Intel® Fortran-specific data type names. For example, in REAL</em>4, the *4 is the data type length specifier.</td>
</tr>
<tr>
<td>deadlock</td>
<td>A bug where the execution of thread A is blocked indefinitely waiting for thread B to perform some action, while thread B is blocked waiting for thread A. For example, two threads on opposite ends of a named pipe can become deadlocked if each thread waits to read data written by the other thread. A single thread can also deadlock itself. See also thread.</td>
</tr>
<tr>
<td>declaration</td>
<td>See specification statement.</td>
</tr>
<tr>
<td>decorated name</td>
<td>An internal representation of a procedure name or variable name that contains information about where it is declared; for procedures, the information includes how it is called. Decorated names are mainly of interest in mixed-language programming, when calling Fortran routines from other languages.</td>
</tr>
<tr>
<td>default character</td>
<td>The kind for character constants if no kind type parameter is specified. Currently, the only kind type parameter for character constants is CHARACTER(1), the default character kind.</td>
</tr>
<tr>
<td>default complex</td>
<td>The kind for complex constants if no kind type parameter is specified. The default complex kind is affected by compiler options specifying double size. If no compiler option is specified, default complex is COMPLEX(4) (COMPLEX*8). See also default real.</td>
</tr>
<tr>
<td>default integer</td>
<td>The kind for integer constants if no kind type parameter is specified. The default integer kind is affected by the INTEGER directive, the OPTIONS statement, and by compiler options specifying integer size. If none of these are specified, default integer is INTEGER(4) (INTEGER*4). If a command line option affecting integer size has been specified, the integer has the kind specified, unless it is outside the range of the kind specified by the option. In this case, the kind type of the integer is the smallest integer kind which can hold the integer.</td>
</tr>
</tbody>
</table>
default logical  The kind for logical constants if no kind type parameter is specified. The default logical kind is affected by the INTEGER directive, the OPTIONS statement, and by compiler options specifying integer size. If none of these are specified, default logical is LOGICAL(4) (LOGICAL*4). See also default integer.

default real  The kind for real constants if no kind type parameter is specified. The default real kind is affected by compiler options specifying real size and by the REAL directive. If neither of these is specified, default real is REAL(4) (REAL*4).
If a real constant is encountered that is outside the range for the default, an error occurs.

deferred-shape array  An array pointer (an array with the POINTER attribute) or an allocatable array (an array with the ALLOCATABLE attribute). The size in each dimension is determined by pointer assignment or when the array is allocated.
The array specification contains a colon (:) for each dimension of the array. No bounds are specified.

definable  A property of variables. A variable is definable if its value can be changed by the appearance of its name or designator on the left of an assignment statement. An example of a variable that is not definable is an allocatable array that has not been allocated.

derived type  A data type that is user-defined and not intrinsic. It requires a type definition to name the type and specify its components (which can be intrinsic or user-defined types). A structure constructor can be used to specify a value of derived type. A component of a structure is referenced using a percent sign (%).
Operations on objects of derived types (structures) must be defined by a function with an OPERATOR interface. Assignment for derived types can be defined intrinsically, or be redefined by a subroutine with an ASSIGNMENT(=) interface. Structures can be used as procedure arguments and function results, and can appear in input and output lists. Also called a user-defined type. See also record, the first definition.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>designator</td>
<td>A name that references a subobject (part of a data object) that can be defined and referenced separately from other parts of the data object. A designator is the name of the object followed by a selector that selects the subobject. For example, B(3) is a designator for an array element. Also called a subobject designator. See also selector and subobject.</td>
</tr>
<tr>
<td>dimension</td>
<td>A range of values for one subscript or index of an array. An array can have from 1 to 7 dimensions. The number of dimensions is the rank of the array.</td>
</tr>
<tr>
<td>dimension bounds</td>
<td>See bounds.</td>
</tr>
<tr>
<td>direct access</td>
<td>A method for retrieving or storing data in which the data (record) is identified by the record number, or the position of the record in the file. The record is accessed directly (nonsequentially); therefore, all information is equally accessible. Also called random access. Contrast with sequential access.</td>
</tr>
<tr>
<td>DLL</td>
<td>See Dynamic Link Library.</td>
</tr>
<tr>
<td>double-byte character set (DBCS)</td>
<td>A mapping of characters to their identifying numeric values, in which each value is 2 bytes wide. Double-byte character sets are sometimes used for languages that have more than 256 characters.</td>
</tr>
<tr>
<td>double-precision constant</td>
<td>A processor approximation to the value of a real number that occupies 8 bytes of memory and can assume a positive, negative, or zero value. The precision is greater than a constant of real (single-precision) type. For the precise ranges of the double-precision constants, see Building Applications: Data Representation Overview. See also denormalized number.</td>
</tr>
<tr>
<td>driver program</td>
<td>A program that is the user interface to the language compiler. It accepts command line options and file names and causes one or more language utilities or system programs to process each file.</td>
</tr>
<tr>
<td>dummy aliasing</td>
<td>The sharing of memory locations between dummy (formal) arguments and other dummy arguments or COMMON variables that are assigned.</td>
</tr>
<tr>
<td>dummy argument</td>
<td>A variable whose name appears in the parenthesized list following the procedure name in a FUNCTION statement, a SUBROUTINE statement, an ENTRY statement, or a statement function statement. A dummy argument takes the value of the corresponding actual argument in the calling program unit (through argument association). Also called a formal argument.</td>
</tr>
<tr>
<td>dummy array</td>
<td>A dummy argument that is an array.</td>
</tr>
<tr>
<td>dummy pointer</td>
<td>A dummy argument that is a pointer.</td>
</tr>
<tr>
<td>dummy procedure</td>
<td>A dummy argument that is specified as a procedure or appears in a procedure reference. The corresponding actual argument must be a procedure.</td>
</tr>
</tbody>
</table>
Dynamic Link Library (DLL) A separate source module compiled and linked independently of the applications that use it. Applications access the DLL through procedure calls. The code for a DLL is not included in the user’s executable image, but the compiler automatically modifies the executable image to point to DLL procedures at run time.

Glossary E

edit descriptor A descriptor in a format specification. It can be a data edit descriptor, control edit descriptor, or string edit descriptor. See also control edit descriptor, data edit descriptor, and string edit descriptor.

element See array element.

elemental Pertains to an intrinsic operation, intrinsic procedure, or assignment statement that is independently applied to either of the following:

- The elements of an array
- Corresponding elements of a set of conformable arrays and scalars

eof-file The condition that exists when all records in a file open for sequential access have been read.

entity A general term referring to any Fortran 95/90 concept; for example, a constant, a variable, a program unit, a statement label, a common block, a construct, an I/O unit and so forth.

environment variable A symbolic variable that represents some element of the operating system, such as a path, a filename, or other literal data.

error number An integer value denoting an I/O error condition, obtained by using the IOSTAT keyword in an I/O statement.

exceptional values For floating-point numbers, values outside the range of normalized numbers, including denormal (subnormal) numbers, infinity, Not-a-Number (NaN) values, zero, and other architecture-defined numbers.

executable construct A CASE, DO, IF, WHERE, or FORALL construct.

executable program A set of program units that include only one main program.

executable statement A statement that specifies an action to be performed or controls one or more computational instructions.

explicit interface A procedure interface whose properties are known within the scope of the calling program, and do not have to be assumed. These properties are the names of the procedure and its dummy arguments, the attributes of a procedure (if it is a function), and the attributes and order of the dummy arguments.
The following have explicit interfaces:

- Internal and module procedures (explicit by definition)
- Intrinsic procedures
- External procedures that have an interface block
- External procedures that are defined by the scoping unit and are recursive
- Dummy procedures that have an interface block

**explicit-shape array**
An array whose rank and bounds are specified when the array is declared.

**expression**
A data reference or a computation formed from operators, operands, and parentheses. The result of an expression is either a scalar value or an array of scalar values.

**extent**
The size of (number of elements in) one dimension of an array.

**external file**
A sequence of records that exists in a medium external to the executing program.

**external procedure**
A procedure that is contained in an external subprogram. External procedures can be used to share information (such as source files, common blocks, and public data in modules) and can be used independently of other procedures and program units. Also called an external routine.

**external subprogram**
A subroutine or function that is not contained in a main program, module, or another subprogram. A module is not a subprogram.

### Glossary F

**field**
Can be either of the following:

- A set of contiguous characters, considered as a single item, in a record or line.
- A substructure of a STRUCTURE declaration.

**field descriptor**
See data edit descriptor.

**field separator**
The comma (,) or slash (/) that separates edit descriptors in a format specification.

**field width**
The total number of characters in the field. See also field, the first definition.
file  A collection of logically related records. If the file is in internal storage, it is an internal file; if the file is on an input/output device, it is an external file.

file access  The way records are accessed (and stored) in a file. The Fortran 95/90 file access modes are sequential and direct.

file handle  A unique identifier that the system assigns to a file when the file is opened or created. A file handle is valid until the file is closed.

file organization  The way records in a file are physically arranged on a storage device. Fortran 95/90 files can have sequential or relative organization.

fixed-length record type  A file format in which all the records are the same length.

floating-point environment  A collection of registers that control the behavior of floating-point (FP) machine instructions and indicate the current FP status. The floating-point environment may include rounding mode controls, exception masks, flush-to-zero controls, exception status flags, and other floating-point related features.

focus window  The window to which keyboard input is directed.

foreground process  On Linux* systems, a process for which the command interpreter is waiting. Its process group is the same as that of its controlling terminal, so the process is allowed to read from or write to the terminal. Contrast with background process.

foreground window  The window the user is currently working with. The system assigns a slightly higher priority to the thread that created the foreground window than it does to other threads.

foreign file  An unformatted file that contains data from a foreign platform, such as data from a CRAY*, IBM*, or big endian IEEE* machine.

format  A specific arrangement of data. A FORMAT statement specifies how data is to be read or written.

format specification  The part of a FORMAT statement that specifies explicit data arrangement. It is a list within parentheses that can include edit descriptors and field separators. A character expression can also specify format; the expression must evaluate to a valid format specification.

formatted data  Data written to a file by using formatted I/O statements. Such data contains ASCII representations of binary values.

formatted I/O statement  An I/O statement specifying a format for data transfer. The format specified can be explicit (specified in a format specification) or implicit (specified using list-directed or namelist formatting). Contrast with unformatted I/O statement. See also list-directed I/O statement and namelist I/O statement.

frame window  The outermost parent window in QuickWin.

</thead>
<tbody>
<tr>
<td>function</td>
<td>A series of statements that perform some operation and return a single value (through the function or result name) to the calling program unit. A function is invoked by a function reference in a main program unit or a subprogram unit. In Fortran 95/90, a function can be used to define a new operator or extend the meaning of an intrinsic operator symbol. The function is invoked by the appearance of the new or extended operator in the expression (along with the appropriate operands). For example, the symbol * can be defined for logical operands, extending its intrinsic definition for numeric operands. See also function subprogram, statement function, and subroutine.</td>
</tr>
<tr>
<td>function reference</td>
<td>Used in an expression to invoke a function, it consists of the function name and its actual arguments. A function reference returns a value (through the function or result name) that is used to evaluate the calling expression.</td>
</tr>
<tr>
<td>function result</td>
<td>The result value associated with a particular execution or call to a function. This result can be of any data type (including derived type) and can be array-valued. In a FUNCTION statement, the RESULT option can be used to give the result a name different from the function name. This option is required for a recursive function that directly calls itself.</td>
</tr>
<tr>
<td>function subprogram</td>
<td>A sequence of statements beginning with a FUNCTION (or optional OPTIONS) statement that is not in an interface block and ending with the corresponding END statement. See also function.</td>
</tr>
</tbody>
</table>

**Glossary G**

<table>
<thead>
<tr>
<th>Term</th>

</thead>
<tbody>
<tr>
<td>generic identifier</td>
<td>A generic name, operator, or assignment specified in an INTERFACE statement that is associated with all of the procedures within the interface block. Also called a generic specification.</td>
</tr>
<tr>
<td>global entity</td>
<td>An entity (a program unit, common block, or external procedure) that can be used with the same meaning throughout the executable program. A global entity has global scope; it is accessible throughout an executable program. See also local entity.</td>
</tr>
<tr>
<td>global section</td>
<td>A data structure (for example, global COMMON) or shareable image section potentially available to all processes in the system.</td>
</tr>
</tbody>
</table>

**Glossary H**

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
</table>
| handle                      | A value (often, but not always, a 32-bit integer) that identifies some operating system resource, for example, a window or a process. The handle value is returned from an operating system call when the
resource is created; your program then passes that value as an argument to subsequent operating system routines to identify which resource is being accessed.

Your program should consider the handle value a "private" type and not try to interpret it as having any specific meaning (for example, an address).

**hexadecimal constant**
A constant that is a string of hexadecimal (base 16) digits (range 0 to 9, or an uppercase or lowercase letter in the range A to F) enclosed by apostrophes or quotation marks and preceded by the letter Z.

**Hollerith constant**
A constant that is a string of printable ASCII characters preceded by \texttt{nH}, where \( n \) is the number of characters in the string (including blanks and tabs).

**host**
Either the main program or subprogram that contains an internal procedure, or the module that contains a module procedure. The data environment of the host is available to the (internal or module) procedure.

**host association**
The process by which a module procedure, internal procedure, or derived-type definition accesses the entities of its host.

---

**Glossary I**

**implicit interface**
A procedure interface whose properties (the collection of names, attributes, and arguments of the procedure) are not known within the scope of the calling program, and have to be assumed. The information is assumed by the calling program from the properties of the procedure name and actual arguments in the procedure call.

**implicit typing**
The mechanism by which the data type for a variable is determined by the beginning letter of the variable name.

**import library**
A .LIB file that contains information about one or more dynamic-link libraries (DLLs), but does not contain the DLL's executable code. To provide the information needed to resolve the external references to DLL functions, the linker uses an import library when building an executable module of a process.

**index**
Can be either of the following:

- The variable used as a loop counter in a DO statement.
- An intrinsic function specifying the starting position of a substring inside a string.

**initialize**
The assignment of an initial value to a variable.
A form of constant expression that is used to specify an initial value for an entity.

An optimization that replaces a subprogram reference (CALL statement or function invocation) with the replicated code of the subprogram.

The data that a program reads or writes. Also, devices to read and write data.

An intrinsic function whose result depends on properties of the principal argument, not the value of the argument.

A constant that is a whole number with no decimal point. It can have a leading sign and is interpreted as a decimal number.

An attribute of a dummy argument that is not a procedure or a pointer. It indicates whether the argument is used to transfer data into the procedure, out of the procedure, or both.

A process that must periodically get user input to do its work. Contrast with background process.

See procedure interface.

The sequence of statements starting with an INTERFACE statement and ending with the corresponding END INTERFACE statement.

The sequence of statements in an interface block starting with a FUNCTION or SUBROUTINE statement and ending with the corresponding END statement. Also called a procedure interface body.

The designated internal storage space (or variable buffer) that is manipulated during input and output. An internal file can be a character variable, character array, character array element, or character substring. In general, an internal file contains one record. However, an internal file that is a character array has one record for each array element.

A procedure (other than a statement function) that is contained within an internal subprogram. The program unit containing an internal procedure is called the host of the internal procedure. The internal procedure (which appears between a CONTAINS and END statement) is local to its host and inherits the host's environment through host association.

A subprogram contained in a main program or another subprogram.

Describes entities defined by the Fortran 95/90 language (such as data types and procedures). Intrinsic entities can be used freely in any scoping unit.

A subprogram supplied as part of the Fortran 95/90 library that performs array, mathematical, numeric, character, bit manipulation, and other miscellaneous functions. Intrinsic procedures are automatically available.
to any Fortran 95/90 program unit (unless specifically overridden by an EXTERNAL statement or a procedure interface block). Also called a built-in or library procedure.

invoke
To call upon; used especially with reference to subprograms. For example, to invoke a function is to execute the function.

iteration count
The number of executions of the DO range, which is determined as follows:
\[(\text{terminal value} - \text{initial value} + \text{increment value}) / \text{increment value}\]

Glossary K

keyword
See argument keyword and statement keyword.

kind type parameter
Indicates the range of an intrinsic data type; for example: INTEGER(KIND=2). For real and complex types, it also indicates precision. If a specific kind parameter is not specified, the kind is the default for that type (for example, default integer). See also default character, default complex, default integer, default logical, and default real.

Glossary L

label
An integer, from 1 to 5 digits long, that precedes a statement and identifies it. For example, labels can be used to refer to a FORMAT statement or branch target statement.

language extension
An Intel® Fortran language element or interpretation that is not part of the Fortran 95 standard.

lexical token
A sequence of one or more characters that have an indivisible interpretation. A lexical token is the smallest meaningful unit (a basic language element) of a Fortran 95/90 statement; for example, constants, and statement keywords.

library routines
Files that contain functions, subroutines, and data that can be used by Fortran programs. For example: one library contains routines that handle the various differences between Fortran and C in argument passing and data types; another contains run-time functions and subroutines for Windows* graphics and QuickWin* applications. Some library routines are intrinsic (automatically available) to Fortran; others may require a specific USE statement to access the module defining the routines. See also intrinsic procedure.
| **line** | A source form record consisting of 0 or more characters. A standard Fortran 95/90 line is limited to a maximum of 132 characters. |
| **linker** | A system program that creates an executable program from one or more object files produced by a language compiler or assembler. The linker resolves external references, acquires referenced library routines, and performs other processing required to create Linux* and Windows* executable files. |
| **list-directed I/O statement** | An implicit, formatted I/O statement that uses an asterisk (*) specifier rather than an explicit format specification. See also formatted I/O statement and namelist I/O statement. |
| **listing** | A printed copy of a program. |
| **literal constant** | A constant without a name; its value is directly specified in a program. See also named constant. |
| **little endian** | A method of data storage in which the least significant bit of a numeric value spanning multiple bytes is in the lowest addressed byte. This is the method used on Intel® systems. Contrast with big endian. |
| **local entity** | An entity that can be used only within the context of a subprogram (its scoping unit); for example, a statement label. A local entity has local scope. See also global entity. |
| **local optimization** | A level of optimization enabling optimizations within the source program unit and recognition of common expressions. See also optimization. |
| **local symbol** | A name defined in a program unit that is not accessible outside of that program unit. |
| **logical constant** | A constant that specifies the value .TRUE. or .FALSE.. |
| **logical expression** | An integer or logical constant, variable, function value, or another constant expression, joined by a relational or logical operator. The logical expression is evaluated to a value of either true or false. For example, .NOT. 6.5 + (B .GT. D). |
| **logical operator** | A symbol that represents an operation on logical expressions. The logical operators are .AND., .OR., .NEQV., .XOR., .EQV., and .NOT.. |
| **logical unit** | A channel in memory through which data transfer occurs between the program and the device or file. See also unit identifier. |
| **longword** | Four contiguous bytes (32 bits) starting on any addressable byte boundary. Bits are numbered 0 to 31. The address of the longword is the address of the byte containing bit 0. When the longword is interpreted as a signed integer, bit 31 is the sign bit. The value of signed integers is in the range -2**31 to 2**31-1. The value of unsigned integers is in the range 0 to 2**32-1. |
| **loop** | A group of statements that are executed repeatedly until an ending condition is reached. |
lower bounds  See bounds.

Glossary M

main program  The first program unit to receive control when a program is run; it exercises control over subprograms. The main program usually contains a PROGRAM statement (or does not contain a SUBROUTINE, FUNCTION, or BLOCK DATA statement). Contrast with subprogram.

makefile  On Linux* and Mac OS* X systems, an argument to the make command containing a sequence of entries that specify dependencies. On Windows* systems, a file passed to the NMAKE utility containing a sequence of entries that specify dependencies. The contents of a makefile override the system built-in rules for maintaining, updating, and regenerating groups of programs. For more information on makefiles on Linux and Mac OS X systems, see make(1). For more information on using makefiles on Windows systems, see Building Applications: Makefile Command-Line Syntax.

many-one array section  An array section with a vector subscript having two or more elements with the same value.

master thread  In an OpenMP* Fortran program, the thread that creates a team of threads when a parallel region (PARALLEL directive construct) is encountered. The statements in the parallel region are then executed in parallel by each thread in the team. At the end of the parallel region, the team threads synchronize and only the master thread continues execution. See also thread.

message file  A Linux* and Mac OS* X catalog that contains the diagnostic message text of errors that can occur during program execution (run time).

metacommand  See compiler directive.

misaligned data  Data not aligned on a natural boundary. See also natural boundary.

module  A program unit that contains specifications and definitions that other program units can access (unless the module entities are declared PRIVATE). Modules are referenced in USE statements.

module procedure  A subroutine or function that is not an internal procedure and is contained in a module. The module procedure appears between a CONTAINS and END statement in its host module, and inherits the host module’s environment through host association. A module procedure can be declared PRIVATE to the module; it is public by default.

multibyte character set  A character set in which each character is identified by using more than one byte. Although Unicode characters are 2 bytes wide, the Unicode character set is not referred to by this term.
multitasking  | The ability of an operating system to execute several programs (tasks) at once.
multithreading | The ability of an operating system to execute different parts of a program, called threads, simultaneously. If the system supports parallel processing, multiple processors may be used to execute the threads.

**Glossary N**

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Identifies an entity within a Fortran program unit (such as a variable, function result, common block, named constant, procedure, program unit, namelist group, or dummy argument). A name can contain letters, digits, underscores (_), and the dollar sign ($) special character. The first character must be a letter or a dollar sign. In FORTRAN 77, this term was called a symbolic name.</td>
</tr>
<tr>
<td>name association</td>
<td>Pertains to argument, host, or use association. See also argument association, host association, and use association.</td>
</tr>
<tr>
<td>named common block</td>
<td>A common block (one or more contiguous areas of storage) with a name. Common blocks are defined by a COMMON statement.</td>
</tr>
<tr>
<td>named constant</td>
<td>A constant that has a name. In FORTRAN 77, this term was called a symbolic constant.</td>
</tr>
<tr>
<td>namelist I/O statement</td>
<td>An implicit, formatted I/O statement that uses a namelist group specifier rather than an explicit format specifier. See also formatted I/O statement and list-directed I/O statement.</td>
</tr>
<tr>
<td>NaN</td>
<td>Not-a-Number. The condition that results from a floating-point operation that has no mathematical meaning; for example, zero divided by zero.</td>
</tr>
<tr>
<td>natural boundary</td>
<td>The virtual address of a data item that is the multiple of the size of its data type. For example, a REAL(8) (REAL*8) data item aligned on natural boundaries has an address that is a multiple of eight.</td>
</tr>
<tr>
<td>naturally aligned record</td>
<td>A record that is aligned on a hardware-specific natural boundary; each field is naturally aligned. (For more information, see <em>Optimizing Applications: Setting Data Type and Alignment.</em>) Contrast with packed record.</td>
</tr>
<tr>
<td>nesting</td>
<td>The placing of one entity (such as a construct, subprogram, format specification, or loop) inside another entity of the same kind. For example, nesting a loop within another loop (a nested loop), or nesting a subroutine within another subroutine (a nested subroutine).</td>
</tr>
<tr>
<td>nonexecutable statement</td>
<td>A Fortran 95/90 statement that describes program attributes, but does not cause any action to be taken when the program is executed.</td>
</tr>
</tbody>
</table>
The state of an object used for synchronization in one of the wait functions is either signaled or nonsignaled. A nonsignaled state can prevent the wait function from returning. See also wait function.

A numeric constant, variable, or function value, or combination of these, joined by numeric operators and parentheses, so that the entire expression can be evaluated to produce a single numeric value. For example, -L or X+(Y-4.5*Z).

A symbol designating an arithmetic operation. In Fortran 95/90, the symbols +, -, *, /, and ** are used to designate addition, subtraction, multiplication, division, and exponentiation, respectively.

The unit of storage for holding a non-pointer scalar value of type default real, default integer, or default logical. One numeric storage unit corresponds to 4 bytes of memory.

Integer, real, or complex type.

**Glossary 0**

- **object**: See data object.
- **object file**: The binary output of a language processor (such as an assembler or compiler), which can either be executed or used as input to the linker.
- **obsolescent feature**: A feature of FORTRAN 77 that is considered to be redundant in Fortran 95/90. These features are still in frequent use.
- **octal constant**: A constant that is a string of octal (base 8) digits (range of 0 to 7) enclosed by apostrophes or quotation marks and preceded by the letter O.
- **operand**: The passive element in an expression on which an operation is performed. Every expression must have at least one operand. For example, in I .NE. J, I and J are operands. Contrast with operator.
- **operation**: A computation involving one or two operands.
- **operator**: The active element in an expression that performs an operation. An expression can have zero or more operators. Intrinsic operators are arithmetic (+, -, *, /, and **) or logical (.AND., .NOT., and so on). For example, in I .NE. J, .NE. is the operator. Executable programs can define operators which are not intrinsic.
- **optimization**: The process of producing efficient object or executing code that takes advantage of the hardware architecture to produce more efficient execution.
optional argument  A dummy argument that has the `OPTIONAL` attribute (or is included in an `OPTIONAL` statement in the procedure definition). This kind of argument does not have to be associated with an actual argument when its procedure is invoked.

order of subscript progression  A characteristic of a multidimensional array in which the leftmost subscripts vary most rapidly. Also called column-major order.

overflow  An error condition occurring when an arithmetic operation yields a result that is larger than the maximum value in the range of a data type.

Glossary P

packed record  A record that starts on an arbitrary byte boundary; each field starts in the next unused byte. Contrast with `naturally aligned record`.

pad  The filling of unused positions in a field or character string with dummy data (such as zeros or blanks).

parallel processing  The simultaneous use of more than one processor (CPU) to execute a program.

parameter  Can be either of the following:

- In general, any quantity of interest in a given situation; often used in place of the term "argument".
- A Fortran 95/90 named constant.

parent process  A process that initiates and controls another process (child). The parent process defines the environment for the child process. Also, the parent process can suspend or terminate without affecting the child process. See also `child process`.

parent window  A window that has one or more child windows. See also `child window`.

pathname  The path from the root directory to a subdirectory or file. See also `root`.

pipe  A connection that allows one program to get its input directly from the output of another program.

platform  A combination of operating system and hardware that provides a distinct environment in which to use a software product (for example, Windows* 2000 on processors using IA-32 architecture).

pointer  Is one of the following:

- A Fortran 95/90 pointer
A data object that has the POINTER attribute. To be referenced or defined, it must be "pointer-associated" with a target (have storage space associated with it). If the pointer is an array, it must be pointer-associated to have a shape. See also pointer association.

- **An integer pointer**
  A data object that contains the address of its paired variable. This is also called a Cray* pointer.

### pointer assignment
The association of a pointer with a target by the execution of a pointer assignment statement or the execution of an assignment statement for a data object of derived type having the pointer as a subobject.

### pointer association
The association of storage space to a Fortran 95/90 pointer by means of a target. A pointer is associated with a target after pointer assignment or the valid execution of an ALLOCATE statement.

### precision
The number of significant digits in a real number. See also double-precision constant, kind type parameter, and single-precision constant.

### primary
The simplest form of an expression. A primary can be any of the following data objects:
- A constant
- A constant subobject (parent is a constant)
- A variable (scalar, structure, array, or pointer; an array cannot be assumed size)
- An array constructor
- A structure constructor
- A function reference
- An expression in parentheses

### primary thread
The initial thread of a process. Also called the main thread or thread 1. See also thread.

### procedure
A computation that can be invoked during program execution. It can be a subroutine or function, an internal, external, dummy or module procedure, or a statement function. A subprogram can define more than one procedure if it contains an ENTRY statement. See also subprogram.
The statements that specify the name and characteristics of a procedure, the name and characteristics of each dummy argument, and the generic identifier (if any) by which the procedure can be referenced. The characteristics of a procedure are fixed, but the remainder of the interface can change in different scoping units. If these properties are all known within the scope of the calling program, the procedure interface is explicit; otherwise it is implicit (deduced from its reference and declaration).

A virtual address space, security profile, a set of threads that execute in the address space of the process, and a set of resources visible to all threads executing in the process. Several thread objects can be associated with a single process.

A set of instructions that can be compiled and executed by itself. Program blocks contain a declaration and an executable section.

A particular common block or local data area for a particular routine containing equivalence groups.

The fundamental component of an executable program. A sequence of statements and comment lines. It can be a main program, a module, an external subprogram, or a block data program unit.

Four contiguous words (64 bits) starting on any addressable byte boundary. Bits are numbered 0 to 63. (Bit 63 is used as the sign bit.) A quadword is identified by the address of the word containing the low-order bit (bit 0). The value of a signed quadword integer is in the range \(-2^{63}\) to \(2^{63}-1\).

The number of dimensions of an array. A scalar has a rank of zero.

A data structure comprising scalar elements with the same data type and organized as a simple linear sequence. See also scalar.

A constant that is a number written with a decimal point, exponent, or both. It can have single precision (REAL(KIND=4)), double precision (REAL(KIND=8)), or quad precision (REAL(KIND=16)).

Can be either of the following:
• A set of logically related data items (in a file) that is treated as a unit; such a record contains one or more fields. This definition applies to I/O records and items that are declared in a record structure.
• One or more data items that are grouped in a structure declaration and specified in a RECORD statement.

record access
The method used to store and retrieve records in a file.

record structure declaration
A block of statements that define the fields in a record. The block begins with a STRUCTURE statement and ends with END STRUCTURE. The name of the structure must be specified in a RECORD statement.

record type
The property that determines whether records in a file are all the same length, of varying length, or use other conventions to define where one record ends and another begins.

recursion
Pertains to a subroutine or function that directly or indirectly references itself.

reference
Can be any of the following:
• For a data object, the appearance of its name, designator, or associated pointer where the value of the object is required. When an object is referenced, it must be defined.
• For a procedure, the appearance of its name, operator symbol, or assignment symbol that causes the procedure to be executed. Procedure reference is also called "calling" or "invoking" a procedure.
• For a module, the appearance of its name in a USE statement.

relational expression
An expression containing one relational operator and two operands of numeric or character type. The result is a value that is true or false. For example, A-C .GE. B+2 or DAY .EQ. 'MONDAY'.

relational operator
The symbols used to express a relational condition or expression. The relational operators are (.EQ., .NE., .LT., .LE., .GT., and .GE.).

relative file organization
A file organization that consists of a series of component positions, called cells, numbered consecutively from 1 to n. Intel Fortran uses these numbered, fixed-length cells to calculate the component's physical position in the file.

relative pathname
A directory path expressed in relation to any directory other than the root directory. Contrast with absolute pathname.

root
On Windows* systems, the top-level directory on a disk drive; it is represented by a backslash (\). For example, C:\ is the root directory for drive C. On Linux* systems, the top-level directory in the file system; it is represented by a slash (/).
A subprogram; a function or procedure. See also function, subroutine, and procedure.

The time during which a computer executes the statements of a program.

**Glossary S**

**saved object**
A variable that retains its association status, allocation status, definition status, and value after execution of a RETURN or END statement in the scoping unit containing the declaration.

**scalar**
Pertaining to data items with a rank of zero. A single data object of any intrinsic or derived data type. Contrast with array. See also rank-one object.

**scalar memory reference**
A reference to a scalar variable, scalar record field, or array element that resolves into a single data item (having a data type) and can be assigned a value with an assignment statement. It is similar to a scalar reference, but it excludes constants, character substrings, and expressions.

**scalar reference**
A reference to a scalar variable, scalar record field, derived-type component, array element, constant, character substring, or expression that resolves into a single data item having a data type.

**scalar variable**
A variable name specifying one storage location.

**scale factor**
A number indicating the location of the decimal point in a real number and, if there is no exponent, the size of the number on input.

**scope**
The portion of a program in which a declaration or a particular name has meaning. Scope can be global (throughout an executable program), scoping unit (local to the scoping unit), or statement (within a statement, or part of a statement).

**scoping unit**
The part of the program in which a name has meaning. It is one of the following:

- A program unit or subprogram
- A derived-type definition
- A procedure interface body

Scoping units cannot overlap, though one scoping unit can contain another scoping unit. The outer scoping unit is called the host scoping unit.

**screen coordinates**
Coordinates relative to the upper left corner of the screen.
section subscript  A subscript list (enclosed in parentheses and appended to the array name) indicating a portion (section) of an array. At least one of the subscripts in the list must be a subscript triplet or vector subscript. The number of section subscripts is the rank of the array. See also array section, subscript, subscript triplet, and vector subscript.

seed  A value (which can be assigned to a variable) that is required in order to properly determine the result of a calculation; for example, the argument i in the random number generator (RAN) function syntax: y = RAN (i)

selector  A mechanism for designating the following:
- Part of a data object (an array element or section, a substring, a derived type, or a structure component)
- The set of values for which a CASE block is executed

sequence  A set ordered by a one-to-one correspondence with the numbers 1 through n, where n is the total number of elements in the sequence. A sequence can be empty (contain no elements).

sequential access  A method for retrieving or storing data in which the data (record) is read from, written to, or removed from a file based on the logical order (sequence) of the record in the file. (The record cannot be accessed directly.) Contrast with direct access.

sequential file organization  A file organization in which records are stored one after the other, in the order in which they were written to the file.

shape  The rank and extents of an array. Shape can be represented by a rank-one array (vector) whose elements are the extents in each dimension.

shape conformance  Pertains to the rule concerning operands of binary intrinsic operations in expressions: to be in shape conformance, the two operands must both be arrays of the same shape, or one or both of the operands must be scalars.

short field termination  The use of a comma (,) to terminate the field of a numeric data edit descriptor. This technique overrides the field width (w) specification in the data edit descriptor and therefore avoids padding of the input field. The comma can only terminate fields less than w characters long. See also data edit descriptor.

signal  The software mechanism used to indicate that an exception condition (abnormal event) has been detected. For example, a signal can be generated by a program or hardware error, or by request of another program.
<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>single-precision constant</td>
<td>A processor approximation of the value of a real number that occupies 4 bytes of memory and can assume a positive, negative, or zero value. The precision is less than a constant of double-precision type. For the precise ranges of the single-precision constants, see Building Applications: Data Representation Overview. See also denormalized number.</td>
</tr>
<tr>
<td>size</td>
<td>The total number of elements in an array (the product of the extents).</td>
</tr>
<tr>
<td>source file</td>
<td>A program or portion of a program library, such as an object file, or image file.</td>
</tr>
<tr>
<td>specification expression</td>
<td>A restricted expression that is of type integer and has a scalar value. This type of expression appears only in the declaration of array bounds and character lengths.</td>
</tr>
<tr>
<td>specification statement</td>
<td>A nonexecutable statement that provides information about the data used in the source program. Such a statement can be used to allocate and initialize variables, arrays, records, and structures, and define other characteristics of names used in a program.</td>
</tr>
<tr>
<td>statement</td>
<td>An instruction in a programming language that represents a step in a sequence of actions or a set of declarations. In Fortran 95/90, an ampersand can be used to continue a statement from one line to another, and a semicolon can be used to separate several statements on one line. There are two main classes of statements: executable and nonexecutable.</td>
</tr>
<tr>
<td>statement function</td>
<td>A computing procedure defined by a single statement in the same program unit in which the procedure is referenced.</td>
</tr>
<tr>
<td>statement function definition</td>
<td>A statement that defines a statement function. Its form is the statement function name (followed by its optional dummy arguments in parentheses), followed by an equal sign (=), followed by a numeric, logical, or character expression. A statement function definition must precede all executable statements and follow all specification statements.</td>
</tr>
<tr>
<td>statement keyword</td>
<td>A word that begins the syntax of a statement. All program statements (except assignment statements and statement function definitions) begin with a statement keyword. Examples are INTEGER, DO, IF, and WRITE.</td>
</tr>
<tr>
<td>statement label</td>
<td>See label.</td>
</tr>
<tr>
<td>static variable</td>
<td>A variable whose storage is allocated for the entire execution of a program.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>storage association</td>
<td>The relationship between two storage sequences when the storage unit of one is the same as the storage unit of the other. Storage association is provided by the <code>COMMON</code> and <code>EQUIVALENCE</code> statements. For modules, pointers, allocatable arrays, and automatic data objects, the <code>SEQUENCE</code> statement defines a storage order for structures.</td>
</tr>
<tr>
<td>storage location</td>
<td>An addressable unit of main memory.</td>
</tr>
<tr>
<td>storage sequence</td>
<td>A sequence of any number of consecutive storage units. The size of a storage sequence is the number of storage units in the storage sequence. A sequence of storage sequences forms a composite storage sequence. See also storage association and storage unit.</td>
</tr>
<tr>
<td>storage unit</td>
<td>In a storage sequence, the number of storage units needed to represent one real, integer, logical, or character value. See also character storage unit, numeric storage unit, and storage sequence.</td>
</tr>
<tr>
<td>stride</td>
<td>The increment between subscript values that can optionally be specified in a subscript triplet. If it is omitted, it is assumed to be one.</td>
</tr>
<tr>
<td>string edit descriptor</td>
<td>A format descriptor that transfers characters to an output record. Can be either of the following:</td>
</tr>
<tr>
<td></td>
<td>- A scalar data object of derived (user-defined) type.</td>
</tr>
<tr>
<td></td>
<td>- An aggregate entity containing one or more fields or components.</td>
</tr>
<tr>
<td>structure component</td>
<td>Can be either of the following:</td>
</tr>
<tr>
<td></td>
<td>- One of the components of a structure.</td>
</tr>
<tr>
<td></td>
<td>- An array whose elements are components of the elements of an array of derived type.</td>
</tr>
<tr>
<td>structure constructor</td>
<td>A mechanism that is used to specify a scalar value of a derived type. A structure constructor is the name of the type followed by a parenthesized list of values for the components of the type.</td>
</tr>
<tr>
<td>subobject</td>
<td>Part of a data object (parent object) that can be referenced and defined separately from other parts of the data object. A subobject can be an array element, an array section, a substring, a derived type, or a structure component. Subobjects are referenced by designators and can be considered to be data objects themselves. See also designator.</td>
</tr>
<tr>
<td>subobject designator</td>
<td>See designator.</td>
</tr>
<tr>
<td>subprogram</td>
<td>A function or subroutine subprogram that can be invoked from another program unit to perform a specific task. A subprogram can define more than one procedure if it contains an ENTRY statement. Contrast with main program. See also procedure.</td>
</tr>
</tbody>
</table>
subroutine  A procedure that can return many values, a single value, or no value to the calling program unit (through arguments). A subroutine is invoked by a CALL statement in another program unit. In Fortran 95/90, a subroutine can also be used to define a new form of assignment (defined assignment), which is different from those intrinsic to Fortran 90. Such assignments are invoked with an ASSIGNMENT(=) interface block rather than the CALL statement. See also function, statement function, and subroutine subprogram.

subroutine subprogram A sequence of statements starting with a SUBROUTINE (or optional OPTIONS) statement and ending with the corresponding END statement. See also subroutine.

subscript A scalar integer expression (enclosed in parentheses and appended to the array name) indicating the position of an array element. The number of subscripts is the rank of the array. See also array element.

subscript triplet An item in a section subscript list specifying a range of values for the array section. A subscript triplet contains at least one colon and has three optional parts: a lower bound, an upper bound, and a stride. Contrast with vector subscript. See also array section and section subscript.

substring A contiguous portion of a scalar character string. Do not confuse this with the substring selector in an array section, where the result is another array section, not a substring.

symbolic name See name.

syntax The formal structure of a statement or command string.

Glossary T

target The named data object associated with a pointer (in the form pointer-object => target). A target is declared in a type declaration statement that contains the TARGET attribute. See also pointer and pointer association.

thread Part of a program that can run at the same time as other parts, usually with some form of communication and/or synchronization among the threads. See also multithreading.

transformational function An intrinsic function that is not an elemental or inquiry function. A transformational function usually changes an array actual argument into a scalar result or another array, rather than applying the argument element by element.

truncation Can be either of the following:
The process of removing one or more characters from the left or right of a number or string.

A technique that approximates a numeric value by dropping its fractional value and using only the integer portion.

type declaration statement  
A nonexecutable statement specifying the data type of one or more variables: an INTEGER, REAL, DOUBLE PRECISION, COMPLEX, DOUBLE COMPLEX, CHARACTER, LOGICAL, or TYPE statement. In Fortran 95/90, a type declaration statement may also specify attributes for the variables. Also called a type declaration or type specification.

type parameter  
Defines an intrinsic data type. The type parameters are kind and length. The kind type parameter (KIND=) specifies the range for the integer data type, the precision and range for real and complex data types, and the machine representation method for the character and logical data types. The length type parameter (LEN=) specifies the length of a character string. See also kind type parameter.

Glossary U

ultimate component  
For a derived type or a structure, a component that is of intrinsic type or has the POINTER attribute, or an ultimate component of a component that is a derived type and does not have the POINTER attribute.

unary operator  
An operator that operates on one operand. For example, the minus sign in -A and the .NOT. operator in .NOT. (I .GT. K).

undefined  
For a data object, the property of not having a determinate value.

underflow  
An error condition occurring when the result of an arithmetic operation yields a result that is smaller than the minimum value in the range of a data type. For example, in unsigned arithmetic, underflow occurs when a result is negative. See also denormalized number.

unformatted data  
Data written to a file by using unformatted I/O statements; for example, binary numbers.

unformatted I/O statement  
An I/O statement that does not contain format specifiers and therefore does not translate the data being transferred. Contrast with formatted I/O statement.

unformatted record  
A record that is transmitted in internal format between internal and external storage.

unit identifier  
The identifier that specifies an external unit or internal file. The identifier can be any one of the following:

- An integer expression whose value must be zero or positive
• An asterisk (*) that corresponds to the default (or implicit) I/O unit
• The name of a character scalar memory reference or character array name reference for an internal file

Also called a device code, or logical unit number.

unspecified storage unit A unit of storage for holding a pointer or a scalar that is not a pointer and is of type other than default integer, default character, or default real.

upper bounds See bounds.

use association The process by which the entities in a module are made accessible to other scoping units (through a USE statement in the scoping unit).

user-defined assignment See defined assignment.

user-defined operator See defined operation.

user-defined type See derived type.

Glossary V

variable A data object (stored in a memory location) whose value can change during program execution. A variable can be a named data object, an array element, an array section, a structure component, or a substring. In FORTRAN 77, a variable was always scalar and named. Contrast with constant.

variable format expression A numeric expression enclosed in angle brackets (<> ) that can be used in a FORMAT statement. If necessary, it is converted to integer type before use.

variable-length record type A file format in which records may be of different lengths.

vector subscript A rank-one array of integer values used as a section subscript to select elements from a parent array. Unlike a subscript triplet, a vector subscript specifies values (within the declared bounds for the dimension) in an arbitrary order. Contrast with subscript triplet. See also array section and section subscript.

Glossary W

wait function A function that blocks the execution of a calling thread until a specified set of conditions has been satisfied.
### whole array
An array reference (for example, in a type declaration statement) that consists of the array name alone, without subscript notation. Whole array operations affect every element in the array. See also [array](#).

### zero-sized array
An array with at least one dimension that has at least one extent of zero. A zero-sized array has a size of zero and contains no elements. See also [array](#).

  extending 3390, 3559
  extent of 1800
  function adding a dimension to 3559
  function combining 3024
  function counting number of true in 2490
  function determining allocation of 2340
  function determining all true in 2335
  function determining any true in 2344
  function packing 3134
  function performing circular shift of 2494
  function performing dot-product multiplication of 2586
  function performing end-off shift on 2632
  function performing matrix multiplication on 2993
  function replicating 3559
  function reshaping 3390
  function returning codepage in 3072
  function returning language and country combinations in 3073
  function returning location of maximum value in 2998
  function returning location of minimum value in 3031
  function returning lower bounds of 2958
  function returning maximum value of elements in 3002
  function returning minimum value of elements in 3035
  function returning shape of 3504
  function returning size (extent) of 3521
  function returning sum of elements in 3590
  function transposing rank-two 3618
  function unpacking 3638
  logical test element-by-element of 2682, 3666
  making equivalent 1863
  masked assignment of 2682, 3666
  mixed-language programming 295
  number of storage elements for 2540
  properties of 1800
  rank of 1800
  referencing 1817
  row-major order 295
  sections of 1807
  shape of 1800
  size of 1800
  subroutine performing quick sort on 3348
  subroutine sorting one-dimensional 3525
  subscript triplets in 1809
  using POINTER to declare 3163, 3166
  vector subscripts in 1810
  volatile 3661
  whole 1803
  array sections 1807, 1809, 1810, 1838
    assigning values to 1838

function returning result value from a remainder operation 2844
function returning value of the kind parameter of an IEEE REAL data type 2846
function returning whether exception flag is signaling 2835
function returning whether IEEE value is finite 2839
function returning whether IEEE value is negative 2841
function returning whether IEEE value is normal 2841
function returning whether IEEE value is Not-a-Number (NaN) 2840
function returning whether one or more of the arguments is Not-a-Number (NaN) 2860
function returning whether processor supports ability to control the underflow mode 2859
function returning whether processor supports IEEE arithmetic 2851
function returning whether processor supports IEEE base conversion rounding during formatted I/O 2855
function returning whether processor supports IEEE denormalized numbers 2852
function returning whether processor supports IEEE divide 2852
function returning whether processor supports IEEE exceptions 2853
function returning whether processor supports IEEE features defined in the standard 2858
function returning whether processor supports IEEE halting 2854
function returning whether processor supports IEEE infinities 2854
function returning whether processor supports IEEE Not-a-Number feature 2856
function returning whether processor supports IEEE rounding mode 2856
function returning whether processor supports IEEE SQRRT 2857
function setting current underflow mode 2850
function storing current rounding mode 2837
function storing current state of floating-point environment 2838
function storing current underflow mode 2839
function storing halting mode for exception 2836
function that controls halting or continuation after an exception 2847

IEEE* floating-point representation (COMPLEX*8) 1730
IEEE* floating-point representation (COMPLEX*16) 1731
IEEE* floating-point representation (COMPLEX*32) 1731
IEEE* exceptions

function clearing status of 2861
function establishing a handler for 2867
function getting or setting status of 2861

IEEE* flags

function clearing 2861
function getting or setting 2861

IEEE* intrinsic modules

function an integer value rounded according to the current rounding mode 2844
function assigning a value to an exception flag 2847
function creating IEEE value 2860
function restoring state of the floating-point environment 2849
function returning argument with copied sign 2835
function returning exponent of radix-independent floating-point number 2845
function returning FP value equal to unbiased exponent of argument 2842
function returning IEEE class 2834
function returning next representable value after X toward Y 2843

IEEE* floating-point formats 1724

images
  function displaying from bitmap file 2976
  function returning storage size of 2888
  function saving into Windows bitmap file 3408
  transferring from memory to screen 3216
IMAGESIZE 2888
IMAGESIZE_W 2888
IMAX0 2995
IMAX1 2995
IMIN0 3028
IMIN1 3028
IMOD 3040
IMPLICIT 1930, 2889
  effect on intrinsic procedures 1930
  implicit format 2031
  implicit interface 1935, 2923
  IMPLICIT NONE 2889
  implicit typing 1800, 2889
  overriding default 2889
  implied-DO lists 1995
  implied-DO loop 1636, 1995
  list in i/o lists 1995
IMPORT 2891
improving 1345, 1630, 1636
  code 1636
  I/O performance 1630
  run-time performance 1636
IMSL® libraries
  option letting you link to 895
IMVBITS 3062
INCHARQQ 2892
INCLUDE 102, 260, 2895
  directory searched for filenames 102, 260
  environment variable 129
include file path
  option adding a directory to 667
  option removing standard directories from 1116
INCLUDE files
  option specifying directory to search for 129
  searching for 260
  using 260
INCLUDE lines 2895
  including files during compilation 2895
inclusive OR 1825, 2929
  function performing 2929
incremental linking
  linker option specifying treatment of 413
INDEX 2898
  index for last occurrence of substring
  function locating 3401
ININT 3071
initialization expressions 1785, 1828, 3626
  for derived-type components 1785
  inquiry functions allowed in 1828
  in type declaration statements 3626
  transformational functions allowed in 1828
initialization values for reduction variables 1348
INITIALIZEFONTS 2899
initializing variables 2500
INITIALSETTINGS 2900
INLINE 2384, 2385, 2388
  option specifying ATTACHES directive 2384, 2385, 2388
inlined code
  option producing source position information for
  676, 896
inline function expansion
  option disabling 749
  option specifying level of 674, 680, 758
inlining 585, 679, 682, 683, 685, 687, 688, 694, 695, 900, 901, 903, 905, 906, 908, 915, 916, 1511, 1512, 1514, 1519, 1636, 1658
  compiler directed 1512
  (continued)
  developer directed 1514
  option disabling full and partial 694, 915
  option disabling partial 695, 916
  option forcing 679, 900
  option specifying lower limit for large routines 685, 905
  option specifying maximum size of function for 585
  option specifying maximum times for a routine 683, 903
  option specifying maximum times for compilation unit 682, 901
  option specifying total size routine can grow 687, 906
  option specifying upper limit for small routine 688, 908
  preemption 1511
inlining options
  option specifying percentage multiplier for 677, 898
INMAX 2901
INOT 3106
input/output editing 2031
input/output lists 1990
input/output statements 2095
input and output files 121
input and output procedures
  table of 2252

  storage 2186
integer edit descriptors 2044
integer editing (I) 2044
INTEGER KIND to hold address
  function returning 2914
integer model 2224, 2820, 3612
  function returning largest number in 2820
  function returning smallest number in 3612
integer pointers 294, 1010, 1051, 3166
  mixed-language programming 294
  option affecting aliasing of 1010, 1051
integers
  converting to RGB values 3399
  directive specifying default kind 2916
  function converting KIND=2 to KIND=4 2983
  function converting KIND=4 to KIND=2 3508
  function converting to quad-precision type 3346
  function converting to single-precision type 3060
  function multiplying two 64-bit signed 3061
  function multiplying two 64-bit unsigned 3060
  function performing bit-level test for 2416
  function returning difference between 2539
  function returning leading zero bits in 2960
  function returning maximum positive 2901
  function returning number of 1 bits in 3187
  function returning parity of 3188
  function returning trailing zero bits in 3615
  function returning two's complement length of 2888
  functions converting to double-precision type 2536,
          2537, 2833
  models for data 2224
  subroutine performing bit-level set and clear for
          2412
INTEGERTORGB 2917
INTEL_LICENSE_FILE environment variable 129
INTEL_PROF_DUMP_CUMULATIVE environment variable
          1574
INTEL_PROF_DUMP_INTERVAL environment variable
          1574
Intel(R) 64 applications 115
Intel(R) 64 architecture based applications
  HLO 1581
  methods of parallelization 1242
  options 1306, 1310
  targeting 1306, 1310
  using intrinsics in 1638
Intel(R) architectures 1611
Intel(R) compatibility libraries for OpenMP* 1321
Intel(R) compiler-generated code 1658
Intel(R) Debugger 161, 168
Intel(R)-extended intrinsics 1638
Intel(R) extension environment variables 1383

Intel(R) Fortran character set 1750
Intel(R) Fortran Compiler command prompt window 95
Intel(R) Fortran language extensions 2233
Intel(R) linking tools 1497
Intel(R) MKL
  option letting you link to 732, 933
Intel(R) Trace Collector API
option inserting probes to call 1020, 1073
Intel(R) Visual Fortran
creating multithread applications 1479
Intel-provided libraries
option linking dynamically 1058
option linking statically 1068
INTENT 2919
intent of arguments 2919
interaction between format specifications and i/o lists 2090
INTERFACE 2923
INTERFACE ASSIGNMENT 2923
interface blocks 279, 657, 1839, 1938, 1940, 1942, 2923, 3047, 3053
for generic names 1938
for mixed-language programming 279
generic identifier in 2923
module procedures in 3047, 3053
option generating for routines 657
pure procedures in 2923
using ASSIGNMENT(=) 1839
using generic assignment in 1942
using generic operators in 1940
using generic procedures in 1938
INTERFACE OPERATOR 2923
interfaces 295, 1918, 1929, 1935, 1937, 1938, 2923
and Fortran array descriptor format 295
explicit 1935, 2923
generic 1938
implicit 1935, 2923
of dummy procedures 1929
of external procedures 1918
of internal procedures 1918
procedures requiring explicit 1937
INTERFACE TO 2926
intermediate files
option saving during compilation 1013, 1054
intermediate language scalar optimizer 1260
intermediate representation (IR) 1497, 1501
intermediate results 1630
using memory for 1630
internal address
function returning 2977
internal files 197, 209, 1918, 1979
interfaces of 1918
rules for using 197
internal procedures 261, 1745, 1897, 1918, 2483
advantages of 261
internal READ statements 2014
rules for 2014
internal subprograms 1636, 1745, 2483
CONTAINS statement 2483
internal WRITE statements 2027
rules for 2027
interprocedural optimizations 306, 2414
INTEROPERABILITY WITH C 306, 2414
interrupt signal
registering a function to call for 3516
interrupt signal handling
function controlling 3513
INTRINSIC 2927

P

P 2074
  edit descriptor 2074
PACK 140, 3134, 3136
   equivalent compiler option for 140
packed array
   function creating 3134
packed structures 1642
PACKTIMEQQ 3138
PAD 2114, 2139
   specifier for INQUIRE 2114
   specifier for OPEN 2139
padding for blanks 208
padding short source lines
   for fixed and tab source 1757
   for free source 1754
page keys
   function determining behavior of 3150
PARALLEL 1351, 2164, 3139, 3142, 3143
general directive 3142, 3143
OpenMP* Fortran directive 2164, 3139
   using SHARED clause in 1351
parallel compiler directives 2164
parallel construct 1352
PARALLEL DO 1342, 1344, 1345, 1346, 1348, 1351,
   1359, 1364, 1392, 3145
   and synchronization constructs 1364
   example of 1359
   SCHEDULE clause 1342
   summary of OpenMP* directives and clauses 1392
   using COPYIN clause in 1344
   using DEFAULT clause in 1345
   using FIRSTPRIVATE clause in 1346
   using LASTPRIVATE clause in 1346
   using PRIVATE clause in 1346
   using REDUCTION clause in 1348
   using SHARED clause in 1351
parallel invocations with makefile 1520
parallelization 545, 869, 1242, 1287, 1447
parallelization 545, 869, 1242, 1287, 1447, 1453,
   1462
diagnostic 1287
option enabling analysis in source code 545, 869
parallel library routines 2230
parallel lint 1331
PARALLEL OpenMP* directive 1344, 1345, 1346, 1348,
   1351, 1364, 1392
parallel processing 1326, 1352
   thread model 1326
parallel programming 1239, 1242
parallel region
   directive defining 3139
   option specifying number of threads to use in 810,
   977
parallel regions 1360, 1392
   directive defining 1360
directives affecting 1360
library routine affecting 1360
PARALLEL SECTIONS 1344, 1345, 1346, 1348, 1351,
   1359, 1364, 1392, 3146
and synchronization constructs 1364
typical example of 1359
summary of OpenMP* directives 1392
using COPYIN clause in 1344
using DEFAULT clause in 1345
using FIRSTPRIVATE clause in 1346
using LASTPRIVATE clause in 1346
using PRIVATE clause in 1346
using REDUCTION clause in 1348
using SHARED clause in 1351
PARALLEL WORKSHARE 1359, 3147
   using 1359
PARAMETER 478, 3148
   option allowing alternative syntax 478
parentheses
   effect in character expressions 1823
   effect in logical expressions 1825
   effect in numeric expressions 1820, 1821
   partial association 2186
PASSDIRKEYSQQ 3150
passing 1623
   array arguments efficiently 1623
   passing by reference
   %REF 3381
path
   function splitting into components 3528
PATH environment variable 129
pathnames
   specifying default 227
   pattern used to fill shapes
   subroutine returning 2759
PAUSE 3156
PEEKCHARQQ 3158
PENDING
   specifier for INQUIRE 2114
performance 1696
   performance analyzer 1643
   performance issues with IPO 1504

function returning fractional part in 2693
function returning largest number in 2820
function returning number closest to unity in 2635
function returning smallest number in 3612
real numbers
directive specifying default kind 3370
function resulting in single-precision type 3371
function returning absolute spacing of 3527
function returning ceiling of 2441
function returning class of IEEE 2691
function returning difference between 2539
function returning floor of 2663
function returning fractional part for model of 3448
function returning scale of model for 3409
function rounding 2342
function truncating 2331
real-time clock
subroutine returning data from 3595
real values
transferring 2049, 2050, 2058
transferring in exponential form 2052
transferring using engineering notation 2054
transferring using scientific notation 2056
REC 1985, 3365, 3673
specifier for READ 3365
specifier for WRITE 3673
reciprocal
function returning 3402
RECL 1630, 2117, 2141
specifier for INQUIRE 2117
specifier for OPEN 1630, 2141
RECORD 3373
record access 223
record I/O 238
record I/O statement specifiers 235
record length 222
record number
identifying for data transfer 1985
record position
specifying 237
records
function checking for end-of-file 2629
option specifying padding for 807, 972
repositioning to first 3397
rewriting 3398
specifying line terminator for formatted files 213
statement to delete 2526
statement writing end-of-file 2605
types of 213, 1979
RECORDSIZE 2143
record specifier 1985, 2200
alternative syntax for 2200
record structure fields 2204, 2609, 3579
references to 2204
record structure items
directive specifying starting address of 3136
record structures 305, 2201, 2209, 2609, 2623, 3124, 3373, 3579, 3634
aggregate assignment 2209
converting to Fortran 95/90 derived types 2201
directive modifying alignment of data in 3124
in mixed-language programming 305
MAP declarations in 2623, 3634
UNION declarations in 2623, 3634
record transfer 225
RECORDTYPE 2117, 2143
specifier for INQUIRE 2117
specifier for OPEN 2143
record type
converting nonnative data using OPEN defaults 187
record types 213
RECTANGLE 3374
RECTANGLE_W 3374
rectangles
functions drawing 3374
subroutines storing screen image defined by 2768
recursion 3377
RECURSIVE 2705, 3377, 3586
in functions 2705
in subroutines 3586
recursive execution
option specifying 1047
recursive procedures 2705, 3377, 3586
as functions 2705
as subroutines 3586
redirecting output 113
redistributable libraries 315
REDUCTION 1342, 1348, 1360, 1371, 1392, 2579, 3139, 3145, 3146, 3378, 3418

subroutines returning floating-point 2785, 3564
STDCALL 2378, 2390
option for ATTRIBUTES directive 2378, 2390
STOP 3575
storage
association 2186, 2636
defining blocks of 2473
dynamically allocating 2338
freeing 2517
function returning byte-size of 3522
sequence 2186
sharing areas of 2636
units 2186
storage association 2186
using ENTRY 2186
storage item
function returning address of 2977
storage sequence 2186
storage units 2186
storing data per thread 1491
strategies for optimization 1251
Stream_CR records 213
Stream_LF records 213, 1630
Streaming SIMD Extensions 1461, 1611, 1671
record 1671
streaming stores
  option generating for optimization 797, 966
stream record type 213
STRICT 140, 3103, 3577
equivalent compiler option for 140
stride 1809
string edit descriptors 2083, 2084
  apostrophe 2083
  H 2084
  quotation mark 2083
strings
  function concatenating copies of 3390
  function locating last nonblank character in 2975
  function returning length minus trailing blanks 2962
  function returning length of 2961
  mixed-language programming 301
  writing unknown length to file or device 2084
STRUCTURE 2609, 3579
structure components 1786
structure constructors 1790
structure declarations 2203
structures
  derived-type 2530, 2617, 3620
  record 2201, 2203
structuring your program 257
SUBMIT/DELETE value for CLOSE(DISPOSE) or CLOSE(STATUS) 2457
SUBMIT value for CLOSE(DISPOSE) or CLOSE(STATUS) 2457
subnormal numbers 1688
subobjects 1798
subprograms 263, 1914, 2417, 2603, 2650, 2705, 2927, 3047, 3053, 3394, 3586
  BLOCK DATA 2417
  effect of RETURN in 3394
  function 2705
  module 3047, 3053
  statement returning control from 2603
  subroutine 3586
  user-written 1914
  using as actual arguments 2650, 2927
SUBROUTINE 3586
subroutine references 2429
subroutines 1897, 1915, 1945, 1947, 2333, 2429, 2627, 2650, 3377, 3586
  effect of ENTRY in 1945
  ELEMENTAL keyword in 3586
  EXTERNAL keyword in 3586
  function running at specified time 2333
subroutines (continued)
  general rules for 1915
  intrinsic 1947
  invoking 2429
  PURE keyword in 3586
  RECURSIVE keyword in 3377, 3586
  statement specifying entry point for 2627
  transferring control to 2429
subroutines in the OpenMP* run-time library 1398, 1406, 1447, 1591, 1595, 1596, 1602
  for loop unrolling 1595
  for OpenMP* 1406
  for optimization 1591
  for prefetching 1602
  for vectorization 1596
  parallel run-time 1447
subscript list 1800, 1804, 1807
  referencing array elements 1804, 1807
subscript progression 1804
subscripts 1804
subscript triplets 1807, 1809
substrings 1783, 1865, 2898, 3401
  function locating index of last occurrence of 3401
  function returning starting position of 2898
  making equivalent 1865
substructure declarations
  for record structures 2204
SUM 3590
sum of array elements
  function returning 3590
support
  for symbolic debugging 165
  SuspendThread 1491
suspension
  of program execution 3156
  SWP 1288, 1605, 3105, 3592
  SWP reports 1288
  using 1605
symbolic constants
  defining floating-point status and control 1706
symbolic names 522, 1748
  option associating with an optional value 522
symbol names
  option using dollar sign when producing 1029
symbols
  predefined preprocessor 153
symbol visibility 647, 1669
  option specifying 647
  specifying 1669

3813
symbol visibility on Linux* 1669
symbol visibility on Mac OS* X 1669
synchronization 1242, 1326, 1360, 1364, 1402, 1447, 1479, 1481, 1491
   changing the number of 1360
   concepts for multithread applications 1479
   constructs 1364
   creating multithread applications 1479
   parallel processing model for 1326
   starting and stopping 1481
   synchronizing 1491
   thread-level parallelism 1242
   thread sleep time 1402
synchronizing multithread programs 1480, 1491
syntax
   for the ifort command 108
   option checking for correct 1070
SYSTEM 3593
SYSTEM_CLOCK 3595
system calls
   using to open files 2148
system codepage
   function returning number for 3081
system command
   function sending to command interpreter 3596
   function sending to shell 3593
system date
   function setting 3441
system errors
   subroutine returning information on 2642
system parameters for language elements 438
system procedures
   table of 2288
system prompt
   subroutine controlling for critical errors 3444
SYSTEMQQ 3596
system subprograms
   CPU_TIME 2492
   DATE 2506
   DATE_AND_TIME 2509
   EXIT 2646
   IDATE 2831
   SECNDS 3417
   SYSTEM_CLOCK 3595
   TIME 3608
system time
   function converting to ASCII string 2456, 2497
   intrinsic returning 3608
   subroutine returning 3609
   system time (continued)
   subroutine setting 3485

T
T 2070
   edit descriptor 2070
T_floating format 1772
tab-format source lines 1760
tab source format 1757, 1760
   lines in 1760
TAN 3598
TAND 3599
tangent
   function returning 3598, 3599
   function returning hyperbolic 3599
   function with argument in degrees 3599
   function with argument in radians 3598
TANH 3599
TARGET 3600
targeting 1306, 1310, 1313
   IA-32 architecture processors 1306
   Intel(R) 64 architecture processors 1306
   Itanium(R) 2 processors 1313
   run-time checking 1310
targets
   allocation of pointer 1877
   assigning values to 1833, 2357
   associating with pointers 1840, 3600
   as variables 1840
   creating storage for 2338
   deallocation of pointer 1880
   declaration of 3600
   requiring explicit interface 1937
TASK 3602
task region
   directive defining 3602
TASKWAIT 3606
tactical applications 1251
TEMP environment variable 129
temporary files 124
   option to keep 124
terminal
   subroutine specifying device name for 3620
terminal statements for DO constructs 2575
TerminateProcess 1495
TerminateThread 1481
terminating format control ( ) 2079
terminating short fields of input data 2066
ternary raster operation constants 3216
test prioritization tool 1552
  examples 1552
  options 1552
  requirements 1552
text
  function controlling truncation of 3671
  function controlling wrapping of 3671
  function returning orientation of 2766
  function returning width for use with OUTGTEXT 2764
  subroutine sending to screen (including blanks) 3130, 3133
  subroutine sending to screen (special fonts) 3130
text color
  function returning RGB value of 2790
text color index
  function returning 2789
  function returning RGB value of 2790
  function setting 3477
  function setting RGB value of 3478
text cursor
  function setting height and width of 3480
text files
  line including 2895
text output
  function returning background color index for 2718
  function returning background RGB color for 2719
  function setting background color index for 3428
  function setting background RGB color for 3429
text position
  subroutine returning 2792
  subroutine setting 3483
text window
  subroutine returning boundaries of 2793
  subroutine scrolling the contents of 3412
  subroutine setting boundaries of 3484
thread affinity 808, 975, 1418
  option specifying 808, 975
threaded applications
  option enabling analysis of 1019, 1072
threaded program execution
  requesting 101
threading 1479
thread local storage 1491
thread pooling 1454
THREADPRIVATE 3607
thread routine format 1484
threads
  compiling and linking multithread applications 101
  thread stacks 1488
  threshold control for auto-parallelization 1287, 1398, 1461
  OpenMP* routines for 1398
  reordering 1461
TIME 2333, 2509, 2795, 2808, 2948, 2987, 3022, 3079, 3485, 3608, 3609, 3640
  ALARM function for subroutines 2333
  function returning accounting of 3022
  function returning for current locale 3079
  routines returning current system 3608, 3609
  subroutine returning 2509, 2795
  subroutine returning Greenwich mean 2808
  subroutine returning in array 2948
  subroutine returning local zone 2987
  subroutine setting system 3485
  subroutine unpacking a packed 3640
time and date
  routine returning as ASCII string 2652
  subroutine packing values for 3138
  subroutine returning 4-digit year 2509
  subroutine returning current system 2509
TIMEF 3611
TINY 3612
TITLE 2147
  specifier for OPEN 2147
  TL 2071
edit descriptor 2071
TMPDIR environment variable 129
TMP environment variable 129
tool options 1532, 1552, 1561
  code coverage tool 1532
  profmerge 1561
  proforder 1561
  test prioritization 1552
tools 97, 99, 929, 969, 1532
  default 97
  option passing options to 969
  option specifying directory for supporting 929
  specifying alternative 99
topology maps 1418
total association 2186
TR 2071
edit descriptor 2071
traceback
  function returning argument eptr for TRACEBACKQQ 2751
  subroutine aiding in 3612
traceback compiler option 359
traceback information
  obtaining with TRACEBACKQQ routine 426
  option providing 1080
  restrictions in using 413
  sample programs 415
  tradeoffs in using 413
  using 412
TRACEBACKQQ 426, 3612
  using 426
tradeoffs
  in using traceback information 413
TRAILZ 3615
transcendental functions
  option replacing calls to 578, 879
TRANSFER 3616
transfer of data
  function performing binary 3616
transformational functions (continued)
  SUM 3590
  TRANSFER 3616
  TRANSPOSE 3618
  TRIM 3619
  UNPACK 3638
transportability of data 433
TRANSPOSE 3618
transposed arrays
  function producing 3618
trigonometric functions 2269
trigonometric procedures 2269
TRIM 3619
troubleshooting 331, 435
  during application development 435
TTYNAM 3620
twos complement
  function returning length in 2888
TYPE 2148, 2530, 2617, 3194, 3620
  for derived types 2530, 2617, 3620
  specifier for OPEN 2148
type aliasability rules
  option affecting adherence to 479, 847
type conversion procedures
  table of 2267
type declarations 2203, 3626
  within record structures 2203
type declaration statements 1846, 1847, 1849, 1852, 1853, 3626
  array 1853
  attributes in 3626
  character 1849
  derived 1852
  double colon separator in 3626
  initialization expressions in 3626
  noncharacter 1847

U

UBC buffers 1630
UBOUND
  in pointer assignment 1860
ULPs 1727
unaligned data 164, 1099, 1613
  option warning about 1099
unambiguous generic procedure references 2175
unambiguous references 2175
unary operations 1818
unbuffered WRITEs 1630
uncalled routines
  option warning about 1099
unconditional DO 2575
unconditional GO TO 2813
undeclared symbols
  option warning about 1099
UNDEFINE 2522, 3632
undefined variables 1798
underflow 1611, 1660
underscore (_) in names 1748
UNFORMATTED 2120
  specifier for INQUIRE 2120
unformatted data
  and nonnative numeric formats 181
unformatted direct-access READ statements 2013
unformatted direct-access WRITE statements 2027
unformatted direct files 208
unformatted files 187, 188, 190, 194, 195, 196, 208, 1630, 2136
  converting nonnative data 187
direct-access 208
  methods of specifying endian format 188
obtaining numeric specifying format 188
using /convert option to specify format 196
using environment variable method to specify format 190
using OPEN(CONVERT=) method to specify format 194
using OPTIONS/CONVERT to specify format 195
unformatted numeric data
  option specifying format of 517
unformatted records 1979
unformatted sequential files 208
unformatted sequential READ statements 2011
unformatted sequential WRITE statements 2025
Unicode* characters 102
uninitialized variables
  option checking for 511
UNION 2623, 3634
UNIT 197, 1983, 3365, 3673
  specifier for READ 3365
  specifier for WRITE 3673
  using for external files 197
  using for internal files 197
unit number
  function testing whether it's a terminal 2939
  unit number 6
    function writing a character to 3215
unit numbers 197
units 1983, 2457, 2903, 3115
  disconnecting 2457
  opening 3115
  statement requesting properties of 2903
UNIT specifier for CLOSE 2457
UNLINK 3637
UNPACK 3638
unpacked array
  function creating 3638
UNPACKTIMEQQ 3640
UNREGISTERMOUSEEVENT 3641
UNROLL 3108, 3643
UNROLL_AND_JAM 3644
UNTIED clause 3602
unused variables
  option warning about 1099
unvectorizable copy 1461
usage rules 1352
USE 3645
use association 2183
user
  function returning group ID of 2764
    function returning ID of 2796
    subroutine returning login name of 2774
user-defined procedures
  elemental 2596
    keyword preventing side effects in 3212
    pure 3212
user-defined types 305, 1784
  mixed-language programming 305
user-defined TYPE statement 2530, 2617, 3620
user functions 1242, 1346, 1352, 1360, 1371, 1379,
  1398, 1447, 1512, 1514, 1530, 1574, 1611, 1630, 1636, 1638, 1643, 1660
  automatic 1660
  auto-parallelization 1242, 1447
dynamic libraries 1398
EQUIVALENCE statements 1636
floating-point conversions 1611
formatted or unformatted files 1630
implied-DO loops 1630
intrinsic 1638
length of 1630
loop assigns for 1346
memory 1630
noniterative worksharing SECTIONS 1371
user functions (continued)
  OpenMP* 1379
  PGO environment 1574
  private scoping for 1352
  profile-guided optimization 1530
  slow arithmetic operators 1636
  timing for an application 1643
  unbuffered WRITEs 1630
  worksharing 1360

user ID
  function returning 2796
  USEROPEN 2148
  USEROPEN specifier 238
  user-written subprograms 1914
  using an external user-written function to open files 2148
  using the compiler and linker from the command line 107
  using the IFPORT portability module 325
utilities 1532, 1561
  profmerge 1561
  proforder 1561

V

VALUE 2389, 2393, 3653
  option for ATTRIBUTES directive 2389, 2393
variable format expressions 2086
variables 283, 589, 691, 746, 928, 934, 1012, 1042, 1046, 1053, 1121, 1748, 1750, 1763, 1779, 1798, 1799, 1800, 1817, 1833, 1840, 1846, 2250, 2352, 2357, 2371, 2402, 2473, 2500, 2518, 2522, 2530, 2617, 2705, 2889, 3064, 3392, 3405, 3572, 3620, 3632
  allocating to stack storage 2402
  allocating to static storage 3572
  assigning initial values to 2500
  assigning value of label to 2352
  assigning values to 1833, 2357
  associating with group name 3064
  automatic 2402
  character 1779
  data types of scalar 1799
  declaring automatic 2402
  declaring derived-type 2530, 2617, 3620
  declaring static 3572
  declaring type for 1846
  directive creating symbolic 2522, 3632

variables (continued)
  directive declaring properties of 2371
  directive generating warnings for undeclared 2518
  directive testing value of 2522, 3632
  direct sharing of 2473
  explicit typing of 1799
  giving initial values to 2500
  how they become defined or undefined 1798
  implicit typing of 1800
  initializing 2500
  length of name 1748
  namelist 3064
  on the stack 2402
  option initializing to zero 1042, 1121
  option placing in DATA section 746, 934
  option placing in static memory 1012, 1053
  option saving always 589, 928
  option specifying default kind for integer 691
  option specifying default kind for logical 691
  option specifying default kind for real 1046
  referencing 1817
  result 2705, 3392
  retaining in memory 3572
  saving values of 3405
  statement defining default types for user-defined 2889
  static 3572
  storage association of 2473
  table of procedures that declare 2250
  targets as 1840
  truncation of values assigned to 1833
  typing of scalar 1799, 1800
  undefined 2518
  using keyword names for 1750
  using modules in mixed-language programming 283
VARYING 2394
  option for ATTRIBUTES directive 2394
VAXD 2130
  value for CONVERT specifier 2130
VAXG 2130
  value for CONVERT specifier 2130
VECTOR ALIGNED 3654, 3659
VECTOR ALWAYS 3109, 3655
VECTOR ALWAYS directive 1596
vector copy 1242, 1294, 1459, 1461, 1475, 1596
  examples 1475
  options 1459
  options for 1242
vector copy (continued)
  overview 1459
  programming guidelines 1459, 1461
  reports 1294
  support for 1596
  VECTOR directive 1596
    option disabling 1032, 1090
    option setting threshold for loops 1036, 1094
  vectorizer
    option controlling diagnostics reported by 1034, 1092
  vectorizing 1461, 1466, 1519
    loops 1466, 1519
  VECTOR NONTEMPORAL 3657, 3658
  VECTOR NONTEMPORAL directive 1596
  vectors
    function performing dot-product multiplication of
    subscripts in 1807, 1810
  vector subscripts 1807, 1810
  VECTOR TEMPORAL 3657, 3658
  VECTOR UNALIGNED 3654, 3659
  VERIFY 3660
  version
    option displaying for driver and compiler 1107
    option displaying information about 716
    option saving in executable or object file 1017, 1062
  viewport area
    subroutine erasing and filling 2451
    subroutine redefining 3488
  viewport-coordinate origin
    subroutine moving 3487
    subroutine setting 3488
  viewport coordinates
    functions filling (color index) 2658
    functions filling (RGB) 2661
    subroutine converting to physical coordinates 2775
    subroutine converting to Windows coordinates 2804
    subroutines converting from physical coordinates
    2798
  viewport origin
    subroutine moving 3487
  VIRTUAL 3661
  VMS* Compatibility
    option specifying 1095
  VOLATILE 1630, 3661
  using for loop collapsing 1630

W

  WAIT 3663
  WaitForMultipleObjects 1491
