Overview

The Intel® Math Kernel Library (Intel® MKL) offers highly optimized, thread-safe math routines for science, engineering, and financial applications that require maximum performance.

Technical Support

Intel provides a support web site, which contains a rich repository of self help information, including getting started tips, known product issues, product errata, license information, user forums, and more. Visit the Intel® MKL support website at http://www.intel.com/software/products/support/.

About This Document

The Intel MKL User’s Guide provides usage information for the library. The usage information covers the organization, configuration, performance, and accuracy of Intel MKL, specifics of routine calls in mixed-language programming, linking, and more.

This guide:

• Focuses on the usage information needed to call Intel MKL routines from user's applications running on the Linux* OS.
• Describes OS-specific usage of Intel MKL, along with OS-independent features.
• Contains usage information for all Intel MKL function domains, listed in Table A-1 (in Appendix A).
• Assumes you have completed the installation of Intel MKL on your system. If you have not completed the installation, see the Intel® Math Kernel Library Installation Guide (file Install.txt).

To reference how to use the library in your application, use this guide in conjunction with the following documents:
• The Intel® Math Kernel Library User’s Guide is intended to assist you in mastering the usage of Intel MKL on Linux. In particular, it:
  • Describes post-installation steps to help you start using the library
  • Shows you how to configure the library with your development environment
  • Acquaints you with the library structure
  • Explains how to link your application to the library and provides simple usage scenarios
  • Describes how to code, compile, and run your application with Intel MKL for Linux.
This guide is intended for Linux programmers with beginner to advanced experience in software development.

**Document Organization**

The document contains the following chapters and appendices:

**Chapter 1** Overview. Introduces the Intel MKL usage information and describes this document’s notational conventions.

**Chapter 2** Getting Started. Describes post-installation steps and gives information needed to start using Intel MKL after its installation.

**Chapter 3** Intel® Math Kernel Library Structure. Discusses the structure of the Intel MKL directory after installation.

**Chapter 4** Configuring Your Development Environment. Explains how to configure Intel MKL with your development environment.

**Chapter 5** Linking Your Application with the Intel® Math Kernel Library. Explains which libraries should be linked with your application for your particular platform; discusses how to build custom dynamic libraries.

**Chapter 6** Managing Performance and Memory. Discusses Intel MKL threading; shows coding techniques and gives hardware configuration tips for improving performance of the library; explains features of the Intel MKL memory management and, in particular, shows how to replace memory functions that the library uses by default with your own ones.

**Chapter 7** Language-specific Usage Options. Discusses mixed-language programming and the use of language-specific interfaces.
Chapter 8 Coding Tips. Presents coding tips that may be helpful to your specific needs.

Chapter 9 Working with the Intel® Math Kernel Library Cluster Software. Discusses usage of ScaLAPACK and Cluster FFTs; in particular, describes linking of your application with these function domains, including C- and Fortran-specific linking examples; gives information on the supported MPI.

Chapter 10 Getting Assistance for Programming in the Eclipse* IDE. Discusses Intel MKL features that software engineers can benefit from when working in the Eclipse* IDE.

Chapter 11 LINPACK and MP LINPACK Benchmarks. Describes the Intel® Optimized LINPACK Benchmark for Linux* and Intel® Optimized MP LINPACK Benchmark for Clusters.

Appendix A Intel® Math Kernel Library Language Interfaces Support. Summarizes information on language interfaces that Intel MKL provides for each function domain, including the respective header files.

Appendix B Support for Third-Party Interfaces. Describes some interfaces that Intel MKL supports.

The document also includes an Index.

**Term and Notational Conventions**

The following term is used to refer to the operating system:

Linux* OS This term refers to information that is valid on all supported Linux* operating systems.

The following notation is used in reference to Intel MKL directories:

<mkl_directory> The main directory where Intel MKL is installed. Replace this placeholder with the specific pathname in the configuring, linking, and building instructions. For more information, see Getting Started.

<Intel Compiler Pro directory> The installation directory for the Intel® C++ Compiler Professional Edition or Intel® Fortran Compiler Professional Edition. For more information, see Getting Started.
Table 1-1 lists the other notational conventions:

<table>
<thead>
<tr>
<th>Notational Conventions</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Italic</td>
<td>Italic is used for emphasis and also indicates document names in body text, for example: see <em>Intel MKL Reference Manual</em></td>
</tr>
<tr>
<td>Monospace lowercase</td>
<td>Indicates filenames, directory names and pathnames, for example:</td>
</tr>
<tr>
<td></td>
<td>libmkl_core.a, /opt/intel/mkl/10.2.0.004</td>
</tr>
<tr>
<td>Monospace lowercase mixed with uppercase</td>
<td>Indicates commands and command-line options, for example:</td>
</tr>
<tr>
<td></td>
<td>icc myprog.c -L$MKLPATH -I$MKLINCLUDE -lmkl -lguide -lpthread;</td>
</tr>
<tr>
<td></td>
<td>C/C++ code fragments, for example:</td>
</tr>
<tr>
<td></td>
<td>a = new double [SIZE*SIZE];</td>
</tr>
<tr>
<td>UPPERCASE MONOSPACE</td>
<td>Indicates system variables, for example, $MKLPATH</td>
</tr>
<tr>
<td>Monospace italic</td>
<td>Indicates a parameter in discussions: routine parameters, for example, lda; makefile parameters, for example, functions_list; etc. When enclosed in angle brackets, indicates a placeholder for an identifier, an expression, a string, a symbol, or a value, for example, &lt;mkl directory&gt;. Substitute one of these items for the placeholder.</td>
</tr>
<tr>
<td>[ items ]</td>
<td>Square brackets indicate that the items enclosed in brackets are optional.</td>
</tr>
<tr>
<td>{ item</td>
<td>item }</td>
</tr>
</tbody>
</table>
Getting Started

This chapter provides some basic usage information and describes post-installation steps to help you start using the Intel® Math Kernel Library (Intel® MKL) on Linux* OS.

Before You Begin

Before you begin using Intel MKL, learning a few important concepts will help you get off to a good start, as shown in Table 2-1.

Table 2-1 What You Need to Know Before You Begin

<table>
<thead>
<tr>
<th>Target platform</th>
<th><strong>Action:</strong> Identify the architecture of your target machine:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• IA-32 or compatible</td>
</tr>
<tr>
<td></td>
<td>• Intel® 64 or compatible</td>
</tr>
<tr>
<td></td>
<td>• IA-64 (Itanium® processor family)</td>
</tr>
<tr>
<td><strong>Reason:</strong></td>
<td>Because Intel MKL libraries are located in directories corresponding to your particular architecture (see Architecture Support), you should provide proper paths on your link lines (see Linking Examples). To configure your development environment for the use with Intel MKL, set your environment variables using the script corresponding to your architecture (see Set Environment Variables for details).</td>
</tr>
</tbody>
</table>

</tr>
</tbody>
</table>

| Range of integer data | Action: If your system is based on the Intel 64 or IA-64 architecture, |
|                       | identify whether your application performs calculations with huge    |
|                       | data arrays (of more than $2^{31}-1$ elements).                      |
| Reason:              | To operate on huge data arrays, you need to select the ILP64 interface, |
|                      | where integers are 64-bit; otherwise, use the default, LP64, interface, |
|                      | where integers are 32-bit (see Support for ILP64 Programming).        |
Table 2-1  What You Need to Know Before You Begin (continued)

<table>
<thead>
<tr>
<th>Threading model</th>
<th>Action: Identify whether and how your application is threaded:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Threaded with the Intel® compiler</td>
</tr>
<tr>
<td></td>
<td>• Threaded with a third-party compiler</td>
</tr>
<tr>
<td></td>
<td>• Not threaded</td>
</tr>
<tr>
<td></td>
<td>Reason: The compiler you use to thread your application determines which threading library you should link with your application. For applications threaded with a third-party compiler you may need to use Intel MKL in the sequential mode (for more information, see Sequential Mode of the Library and Linking with Threading Libraries).</td>
</tr>
<tr>
<td></td>
<td>Action: Determine the number of threads you want Intel MKL to use.</td>
</tr>
<tr>
<td></td>
<td>Reason: Intel MKL is based on the OpenMP* threading. By default, the OpenMP* software sets the number of threads that Intel MKL uses. If you need a different number, you have to set it yourself using one of the available mechanisms. For more information, see Using the Intel® MKL Parallelism.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Linking model</th>
<th>Action: Decide which linking model is appropriate for linking your application with Intel MKL libraries:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Static</td>
</tr>
<tr>
<td></td>
<td>• Dynamic</td>
</tr>
<tr>
<td></td>
<td>Reason: For information on the benefits of each linking model, link command syntax and examples, link libraries, and other linking topics, like how to save disk space by creating a custom dynamic library, see Linking Your Application with the Intel® Math Kernel Library.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>MPI used</th>
<th>Action: Decide what MPI you will use with the Intel MKL cluster software. You are strongly encouraged to use Intel® MPI 3.x.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Reason: To link your application with ScaLAPACK and/or Cluster FFT, the libraries corresponding to your particular MPI should be listed on the link line (see Working with the Intel® Math Kernel Library Cluster Software).</td>
</tr>
</tbody>
</table>

Compiler Support

Intel MKL supports compilers identified in the Release Notes. However, the library has been successfully used with other compilers as well.

Intel MKL provides a set of include files to simplify program development by specifying enumerated values and prototypes for the respective functions (for the list of include files, see Table A-2). Calling Intel MKL functions from your application without an appropriate include file may lead to incorrect behavior of the functions.

Steps to Get Started

This section helps you to get started with Intel MKL on Linux® OS.
Check Your Installation

After installing Intel MKL, verify that the library has been properly installed and configured.

1. Check that the directory you chose for the installation has been created. The Intel MKL default installation directory may be one of the following:
   - /opt/intel/mkl/RR.r.y.xxx, where RR.r is the version number, y is the release-update number, and xxx is the package number, for example, /opt/intel/mkl/10.2.0.004
   - <Intel Compiler Pro directory>/mkl, for example, /opt/intel/Compiler/11.1/015/mkl.

2. If you choose to keep multiple versions of Intel MKL installed on your system, update your build scripts so that they point to the desired version.

3. Check that the following six files are placed in the tools/environment directory:
   - mklvars32.sh
   - mklvars32.csh
   - mklvarsem64t.sh
   - mklvarsem64t.csh
   - mklvars64.sh
   - mklvars64.csh
   You can use these files to set environment variables in the current user shell.

4. To check the high-level and detailed structure of the Intel MKL installation directory, see Chapter 3.

Set Environment Variables

When the installation of Intel MKL for the Linux* OS is complete, you can use three scripts mklvars32, mklvarsem64t, and mklvars64 with two flavors each (.sh and .csh) in the tools/environment directory to set the environment variables INCLUDE, MKLROOT, LD_LIBRARY_PATH, MANPATH, LIBRARY_PATH, CPATH, FPATH, and NLSPATH in the user shell. For further configuring the library, see Chapter 4.

Use a Web-based Linking Advisor

Intel MKL provides a web-based linking advisor to help you choose the libraries and options to specify on a link line for your application.

The advisor types to a screen the link line depending on your Intel MKL usage scenario, specifically: the operating system, architecture, compiler, static or dynamic linking model, length of integers (32-bit or 64-bit), threaded or sequential mode of Intel MKL operation, and so on. Copy-paste the output to your link line.

For more information on linking with Intel MKL, see Chapter 5 and specifically Table 5-1 for a list of typical link libraries.

**Use Intel MKL Code Examples**

Intel MKL package includes code examples, located in the examples subdirectory of the Intel MKL installation directory. The examples provide the most direct way for you to find out:

- Whether Intel MKL is working on your system
- How you should call the library
- How to link the library

The examples are grouped in subdirectories mainly by Intel MKL function domains and programming languages. For instance, subdirectory examples/spblas contains Sparse BLAS examples, and subdirectory examples/vmlc contains VML examples in C. Source code for the examples is in the next level sources subdirectory.

To compile, build, and run the examples, use the makefile provided. For information on how to use it, refer to the makefile header.

See also:

[High-level Directory Structure](#).
The chapter discusses the structure of the Intel® Math Kernel Library (Intel® MKL), including the Intel MKL directory structure, architecture-specific implementations, supported programming interfaces, and more.

Starting with version 10.0, Intel MKL employs a layered model to streamline the library structure, reduce its size, and add usage flexibility.

See also: Layered Model Concept.

### High-level Directory Structure

Table 3-1 shows a high-level directory structure of Intel MKL after installation.

<table>

Layered Model Concept

Starting with release 10.0, Intel MKL employs a layered model.

There are four essential parts of the library:

1. Interface layer
2. Threading layer
3. Computational layer

The first part adapts Intel MKL to interface-related issues, for example, whether to use 32-bit or 64-bit integer types, or how different compilers return function values. The second part adapts the library to the OpenMP* implementations used by different threading compilers or to the non-threaded usage mode. The Computational layer is the bulk of the library, which is isolated in a separate part to save space. Rather than generate one library for each of the cases within those parts and thus create a geometric explosion of possibilities, Intel MKL has broken down each part into independent libraries corresponding to those cases. You can combine these libraries to meet your needs. Once the interface library is selected, the threading library you select picks up that interface, and the computational libraries use interfaces and threading chosen in the first two layers.

Interface Layer. This layer provides matching between compiled code of your application and the threading and/or computational parts of the library. This layer provides:

- The LP64 and ILP64 interfaces (see Support for ILP64 Programming for details)
- Compatibility with compilers that return function values differently
- A mapping between single-precision names and double-precision names for applications using Cray*-style naming (SP2DP interface)
NOTE. SP2DP interface supports Cray-style naming in applications targeted for the Intel 64 or IA-64 architecture and using the ILP64 interface. SP2DP interface provides a mapping between single-precision names (for both real and complex types) in the application and double-precision names in Intel MKL BLAS and LAPACK. Function names are mapped as shown in the following example for BLAS functions *GEMM:

- **SGEMM** -> **DGEMM**
- **DGBMM** -> **DGEMM**
- **CGEMM** -> **ZGEMM**
- **ZGEMM** -> **ZGEMM**

Mind that no changes are made to double-precision names.

### Threading Layer

This layer provides:

- A way to link threaded Intel MKL with different threading compilers.
- An ability for the user to link with a threaded or sequential mode of the library.

This layer is compiled for different environments (threaded or sequential) and compilers (from Intel, GNU*, and so on).

### Computational Layer

This layer is the heart of Intel MKL. For any given processor architecture (IA-32, IA-64, or Intel® 64) and OS, this layer has only one computational library to link with, regardless of the Interface and Threading layer. The Computational layer accommodates multiple architectures through identification of architecture features and chooses the appropriate binary code at run time.

### Compiler Support Run-time Libraries (RTL, for brevity)

This layer provides RTL support. Not all RTLs are delivered with Intel MKL. Except those that are relevant to the Intel MKL cluster software, the only RTLs provided are Intel® compiler RTLs: Intel® Compatibility OpenMP* run-time library (libiomp) and Intel® Legacy OpenMP* run-time library (libguide). To thread using third-party threading compilers, use libraries in the Threading layer or an appropriate compatibility library (for more information, see Linking with Threading Libraries).

### Sequential Mode of the Library

You can use Intel MKL in a sequential (non-threaded) mode. It requires no Compatibility OpenMP* or Legacy OpenMP* run-time library, and does not respond to the environment variable **OMP_NUM_THREADS** or its Intel MKL equivalents. In this mode, Intel MKL runs unthreaded code. However, it is thread-safe\(^1\), which means that you can use it in a parallel region from your own OpenMP* code. You should use the library in the sequential mode...
only if you have a particular reason not to use Intel MKL threading. The sequential mode may be helpful when using Intel MKL with programs threaded with some non-Intel compilers or in other situations where you may, for various reasons, need a non-threaded version of the library (for instance, in some MPI cases). To obtain Intel MKL running in the sequential mode, in the Threading layer, choose the *sequential.* library to link.

Note that the *sequential.* library depends on the POSIX threads library (`pthread`), which is used to make the Intel MKL software thread-safe and should be listed on the link line.

Avoiding Conflicts in the Execution Environment
Linking Examples.

Support for ILP64 Programming

The Intel MKL ILP64 libraries use the 64-bit integer type (necessary for indexing huge arrays, with more than $2^{31}-1$ elements), whereas the LP64 libraries index arrays with the 32-bit integer type.

The LP64 and ILP64 interfaces are supported in the Interface layer (see Layered Model Concept and Directory Structure in Detail for more information).

The ILP64 interface is provided for the following two reasons:

• To support huge data arrays (with more than $2^{31}-1$ elements)
• To enable compiling your Fortran code with the –i8 compiler option

It is up to you to choose which interface to use. Choose the LP64 interface for compatibility with the previous Intel MKL versions because "LP64" is just a new name for the only interface that the Intel MKL versions lower than 9.1 provided. Choose the ILP64 interface if your application uses Intel MKL for calculations with huge data arrays or the library may be used so in future.

Intel MKL provides the same include directory for the ILP64 and LP64 interfaces.

Compiling for LP64/ILP64

Table 3-2 shows how to compile for the ILP64 and LP64 interfaces:

Table 3-2 Compiling for the ILP64 and LP64 Interfaces

<table>
<thead>
<tr>
<th>Fortran</th>
<th>C or C++</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compiling for ILP64</td>
<td>ifort -i8 -I&lt;mkl directory&gt;/include ...</td>
</tr>
<tr>
<td>Compiling for LP64</td>
<td>ifort -I&lt;mkl directory&gt;/include ...</td>
</tr>
<tr>
<td>Compiling for ILP64</td>
<td>icc -DMKL_ILP64 -I&lt;mkl directory&gt;/include ...</td>
</tr>
<tr>
<td>Compiling for LP64</td>
<td>icc -I&lt;mkl directory&gt;/include ...</td>
</tr>
</tbody>
</table>

NOTE. Linking of the application compiled with the -i8 or -DMKL_ILP64 option to the LP64 libraries may result in unpredictable consequences and erroneous output.

Coding for ILP64

You do not need to change existing code if you are not using the ILP64 interface.

To migrate to ILP64 or write new code for ILP64, use appropriate types for parameters of the Intel MKL functions and subroutines (see Table 3-3):

Table 3-3 Integer Types

<table>
<thead>
<tr>
<th>32-bit integers</th>
<th>Fortran</th>
<th>C or C++</th>
</tr>
</thead>
<tbody>
<tr>
<td>Universal integers for ILP64/LP64:</td>
<td>INTEGER*4 or INTEGER(KIND=4)</td>
<td>int</td>
</tr>
<tr>
<td>• 64-bit for ILP64</td>
<td>INTEGER without specifying KIND</td>
<td>MKL_INT</td>
</tr>
<tr>
<td>• 32-bit otherwise</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Universal integers for ILP64/LP64:</td>
<td>INTEGER*8 or INTEGER(KIND=8)</td>
<td>MKL_INT64</td>
</tr>
<tr>
<td>• 64-bit integers</td>
<td>INTEGER without specifying KIND</td>
<td>MKL_LONG</td>
</tr>
<tr>
<td>FFT interface integers for ILP64/LP64</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Browsing the Intel MKL Include Files

Given a function with integer parameters, the Reference Manual does not explain which parameters become 64-bit and which remain 32-bit for ILP64, and you are encouraged to browse the include files, examples, and tests for the ILP64 interface details. For their location, see Table 3-1.

You are encouraged to start with browsing the include files, listed in Table A-2.

Some function domains that support only a Fortran interface (see Table A-1), provide header files for C/C++ in the include directory. Such * . h files enable using a Fortran binary interface from C/C++ code. These files can also be used to understand the ILP64 usage.

Limitations

All Intel MKL function domains support ILP64 programming with the following exceptions:

- FFTW interfaces to Intel MKL:
  - FFTW 2.x wrappers do not support ILP64.
  - FFTW 3.2 wrappers support ILP64 by a dedicated set of functions plan_guru64.
- GMP* arithmetic functions do not support ILP64.

Architecture Support

Intel MKL for Linux* OS provides three architecture-specific implementations. Table 3-4 lists the supported architectures and directories where each architecture-specific implementation is located.

<table>
<thead>
<tr>
<th>Architecture</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>IA-32 or compatible</td>
<td>&lt;mkl directory&gt;/lib/32</td>
</tr>
<tr>
<td>Intel® 64 or compatible</td>
<td>&lt;mkl directory&gt;/lib/em64t</td>
</tr>
<tr>
<td>IA-64</td>
<td>&lt;mkl directory&gt;/lib/64</td>
</tr>
</tbody>
</table>

See a detailed structure of these directories in Table 3-5, Table 3-6, and Table 3-7.
Directory Structure in Detail

The information in the tables below shows a detailed structure of the Intel MKL architecture-specific directories. For the list of additional interface libraries that can be generated in these directories using makefiles in the interfaces directory, see Using Language-Specific Interfaces with Intel® MKL. For the contents of the doc directory, see Contents of the Documentation Directory. For the contents of subdirectories in the benchmarks directory, see LINPACK and MP LINPACK Benchmarks. Note that in MKL 10.2, libraries that provided link line compatibility with the Intel MKL versions 9.x and lower were removed.

Accessing Man Pages

During installation, the man pages for the Intel MKL functions are copied to subdirectory man/en_US/man3 of the Intel MKL installation directory.

To make the man pages accessible through the man command in your command shell, add the directory with the man pages to the MANPATH environment variable (see Set Environment Variables).

Once the environment variable is set, to view the man page for an Intel MKL function, enter the following command in your command shell:

```
man <function base name>
```

In this release, `<function base name>` is the function name with omitted prefixes denoting data type, precision, or function domain.

Examples:
• For the BLAS function `ddot`, enter `man dot`
• For the ScaLAPACK function `pzgeql2`, enter `man pgeql2`
• For the FFT function `DftiCommitDescriptor`, enter `man CommitDescriptor`

**NOTE.** Function names in the `man` command are case-sensitive.
Configuring Your Development Environment

This chapter explains how to configure your development environment for the use with the Intel® Math Kernel Library (Intel® MKL).

Chapter 2 explains how to set environment variables INCLUDE, MKLROOT, LD_LIBRARY_PATH, MANPATH, LIBRARY_PATH, CPATH, FPATH, and NLSPATH. Section Automating Setting of Environment Variables explains how to automate setting of these variables at startup.

For information on how to set up environment variables for threading, see Setting the Number of Threads Using OpenMP® Environment Variable.

Automating Setting of Environment Variables

To automate setting of the INCLUDE, MKLROOT, LD_LIBRARY_PATH, MANPATH, LIBRARY_PATH, CPATH, FPATH, and NLSPATH environment variables, add mklvars*.sh to your shell profile so that each time you login, the script will automatically execute and set the path to the appropriate Intel MKL directories.

With the local user account, you should edit the following files by adding the appropriate script to the path manipulation section right before exporting variables:

- bash:
  ~/.bash_profile, ~/.bash_login or ~/.profile

  # setting up MKL environment for bash
  . <absolute_path_to_installed_MKL>/tools/environment/mklvars<arch>.sh

- sh:
  ~/.profile

  # setting up MKL environment for sh
In the above commands, replace `mklvars<arch>` with `mklvars32`, `mklvarsem64t`, or `mklvars64`.

If you have super user permissions, you can add the same commands to a general-system file in `/etc/profile` (for bash and sh) or in `/etc/csh.login` (for csh).

Before uninstalling Intel MKL, remove the above commands from all profile files where the script execution was added, to avoid problems logging in later.

### Configuring the Eclipse* IDE CDT to Link with Intel MKL

This section describes how to configure the Eclipse* IDE C/C++ Development Tools (CDT) 3.x and 4.0 to link with Intel MKL.

**TIP.** After linking your CDT with Intel MKL, you can benefit from the Eclipse-provided code assist feature. See Code/Context Assist description in Eclipse Help.

### Configuring the Eclipse* IDE CDT 4.0

To configure Eclipse CDT 4.0 to link with Intel MKL, follow the instructions below:

1. If the tool-chain/compiler integration supports include path options, go to the **Includes** tab of the **C/C++ General > Paths and Symbols** property page and set the Intel MKL include path, that is, `<mkl directory>/include`.

2. If the tool-chain/compiler integration supports library path options, go to the **Library Paths** tab of the **C/C++ General > Paths and Symbols** property page and set the Intel MKL library path for the target architecture, such as `<mkl directory>/lib/em64t`.
3. For a particular build, go to the **Tool Settings** tab of the **C/C++ Build > Settings** property page and specify the names of the Intel MKL libraries to link with your application, for example, `mkl_solver_lp64` and `mkl_core` (compilers typically require library names rather than library file names, so omit the "lib" prefix and "a" extension). To learn how to choose the libraries, see [Selecting Libraries to Link](#). The name of the particular setting where libraries are specified depends upon the compiler integration.

Note that the compiler/linker will automatically pick up the include and library paths settings only if the automatic makefile generation is turned on; if not, specify the include and library paths directly in the makefile.

### Configuring the Eclipse* IDE CDT 3.x

To configure Eclipse CDT 3.x to link with Intel MKL, follow the instructions below:

- For Standard Make projects:
  1. Go to **C/C++ Include Paths and Symbols** property page and set the Intel MKL include path to `<mkl directory>/include`.
  2. Go to the **Libraries** tab of the **C/C++ Project Paths** property page and set the Intel MKL libraries to link with your applications, for example, `<mkl directory>/lib/em64t/libmkl_intel_lp64.a`, `<mkl directory>/lib/em64t/libmkl_intel_thread.a`, and `<mkl directory>/lib/em64t/libmkl_core.a`. To learn how to choose the libraries, see [Selecting Libraries to Link](#).

Note that with the Standard Make, the above settings are needed for the CDT internal functionality only. The compiler/linker will not automatically pick up these settings and you will still have to specify them directly in the makefile.

- For Managed Make projects, you can specify settings for a particular build. To do this:
  1. Go to the **Tool Settings** tab of the **C/C++ Build** property page. All the settings you need to specify are on this page. Names of the particular settings depend upon the compiler integration and therefore are not given below.
  2. If the compiler integration supports include path options, set the Intel MKL include path to `<mkl_directory>/include`.
  3. If the compiler integration supports library path options, set a path to the Intel MKL libraries for the target architecture, such as `<mkl directory>/lib/em64t`.
  4. Specify the names of the Intel MKL libraries to link with your application, for example, `mkl_solver_lp64` and `mkl_core` (compilers typically require library names rather than library file names, so omit the "lib" prefix and "a" extension). To learn how to choose the libraries, see [Selecting Libraries to Link](#).
Configuring the Out-of-Core (OOC) DSS/PARDISO* Solver

When using the configuration file for the OOC DSS/PARDISO* Solver, be aware that the maximum length of the path lines in the file is 1000 characters.

For more information, see the "Sparse Solver Routines" chapter in the Intel MKL Reference Manual.
This chapter discusses linking your applications with the Intel® Math Kernel Library
(Intel® MKL) for the Linux* OS. The chapter provides information on the libraries that
should be linked with your application, presents linking examples, and explains building of
custom shared objects.

To link with Intel MKL, which employs the layered linking model, choose one library from
the Interface layer, one library from the Threading layer, the library from the
Computational layer, and, if necessary, add run-time libraries. Table 5-1 lists typical sets of
libraries that suffice to link with Intel MKL.

### Table 5-1 Typical Link Libraries

<table>
<thead>
<tr>

<td>libmkl_core.so</td>
<td>libiomp5.so</td>
</tr>
</tbody>
</table>

For exceptions and alternatives to the libraries listed above, see [Selecting Libraries to Link](#).

See also: [Listing Libraries on a Link Line](#).
Listing Libraries on a Link Line

To link with Intel MKL libraries, specify paths and libraries on the link line as shown below.

```
<files to link>
-L<MKL path> -I<MKL include>
[-I<MKL include>/32|em64t|{ilp64|lp64}|64/{ilp64|lp64}]
[-lmkl_blas{95|95_ilp64|95_lp64}]
[-lmkl_lapack{95|95_ilp64|95_lp64}]
[<cluster components>]
-llmkl_{intel|intel_ilp64|intel_lp64|intel_sp2dp|gf|gf_ilp64|gf_lp64}
-llmkl_{intel_thread|gnu_thread|pgi_thread|sequential}
[-llmkl_solver_{lp64|ilp64}]
[-llmkl_lapack] -llmkl_core
(-liomp5|-lguide) [-lpthread] [-lm]
```

See [Selecting Libraries to Link](#) for details of this syntax usage and specific recommendations on which libraries to link depending on your Intel MKL usage scenario.

See [Working with the Intel® Math Kernel Library Cluster Software](#) on linking with libraries denoted as `<cluster components>`.

In case of static linking, enclose the cluster components, interface, threading, and computational libraries in grouping symbols (for example, `-Wl,--start-group
$MKLPATH/libmkl_cdft_core.a $MKLPATH/libmkl_blacs_intelmpi_ilp64.a
$MKLPATH/libmkl_intel_ilp64.a $MKLPATH/libmkl_intel_thread.a
$MKLPATH/libmkl_core.a -Wl,--end-group`). See specific examples in the [Linking Examples](#) section.

The order of listing libraries on the link line is essential, except for the libraries enclosed in the grouping symbols above.
Selecting Libraries to Link

This section recommends which libraries to link depending on your Intel MKL usage scenario and provides details of the linking in subsections:

- Linking with Fortran 95 Interface Libraries
- Linking with Threading Libraries
- Linking with Computational Libraries
- Linking with Compiler Support RTLs
- Linking with System Libraries
- Linking Examples

Linking with Fortran 95 Interface Libraries

The `libmkl_blas95.a`, `libmkl_blas95_lp64.a`, `libmkl_blas95_ilp64.a`, `libmkl_lapack95.a`, `libmkl_lapack95_lp64.a`, and `libmkl_lapack95_ilp64.a` libraries contain Fortran 95 interfaces for BLAS and LAPACK, respectively, which are compiler-dependent. In the Intel MKL package, they are prebuilt for the Intel® Fortran compiler. If you are using a different compiler, build these libraries before using the interface. (See Fortran 95 Interfaces to LAPACK and BLAS and Compiler-dependent Functions and Fortran 90 Modules for details on building the libraries and on why source code is distributed in this case.)

Linking with Threading Libraries

Several compilers that Intel MKL supports use the OpenMP* threading technology. Starting with version 10.0, Intel MKL supports the implementations of OpenMP* that those compilers provide. If an application using OpenMP* and compiled with such a compiler calls Intel MKL 10.0 or lower, which is threaded with Intel® compilers, performance issues and even failures may arise because threading libraries from different compilers are not compatible. Starting with Intel MKL 10.0, solutions for these issues are provided from the Threading Layer and the Compiler Support Run-time Libraries (RTL).

Threading Layer. Because of the internal structure of the library, threading represents a small amount of code. This code is compiled by different compilers (Intel, gnu and PGI* compilers on Linux*), and you should link in the appropriate threading library.

RTL. This layer includes run-time libraries of the Intel compiler: the Intel® Compatibility OpenMP* run-time library `libiomp` and Intel® Legacy OpenMP* run-time library `libguide`. The Compatibility library `libiomp` is an extension of `libguide` that provides
support for one additional threading compiler on Linux (GNU). That is, a program threaded with a GNU compiler can safely be linked with Intel MKL and libiomp and execute efficiently and effectively. So, you are encouraged to use libiomp rather than libguide.

Table 5-2 shows different scenarios, depending on the threading compiler used, and the possibilities for each scenario to choose the threading libraries and RTL when using Intel MKL (static cases only):

## Table 5-2 Selecting Threading Libraries

### Linking with Computational Libraries

Typically, with the layered linking model, you must link your application with only one computational library. However, certain Intel MKL function domains require several computational link libraries.

For each Intel MKL function domain, Table 5-3 lists computational libraries that you must include in the link line. For more information on linking with ScaLAPACK and Cluster FFTs, see also Linking with ScaLAPACK and Cluster FFTs.
<table>
<thead>
<tr>

</tbody>
</table>
### Linking with Compiler Support RTLs

You are strongly encouraged to dynamically link in the Intel Compatibility OpenMP* run-time library libiomp or Intel Legacy OpenMP* run-time library libguide. Linking to static OpenMP* run-time library is not recommended because it is very easy with complex software to link in more than one copy of the library. This causes performance problems (too many threads) and may cause correctness problems if more than one copy is initialized.

You are advised to link with libiomp and libguide dynamically even if other libraries are linked statically.

However, if you link with libiomp/libguide statically, the version of libiomp/libguide you link with depends on which compiler you use:

---

1. Add also the library with BLACS routines corresponding to the used MPI. For details, see Linking with ScaLAPACK and Cluster FFTs.

#### Table 5-3: Computational Libraries to Link, by Function Domain (continued)

See also:

[Linking with Compiler Support RTLs](#)
• If you use the Intel compiler, link in the libiomp/libguide version that comes with the compiler, that is, use the -openmp option.

• If you do not use the Intel compiler, link in the libiomp/libguide version that comes with Intel MKL.

If you link with dynamic versions of libiomp/libguide (recommended), that is, use libiomp5.so or libguide.so, make sure LD_LIBRARY_PATH is defined correctly. See Set Environment Variables for details.

Linking with System Libraries

To use the Intel MKL FFT, Trigonometric Transform, or Poisson, Laplace, and Helmholtz Solver routines, link in the math support system library by adding "-lm" to the link line.

On Linux OS*, libiomp/libguide both rely on the native pthread library for multi-threading. Any time libiomp/libguide is required, add -lpthread to your link line afterwards (the order of listing libraries is important).

Linking Examples

The section provides specific linking examples that use Intel® compilers on systems based on the IA-32, Intel® 64, and IA-64 architectures. In these examples, <MKL path> and <MKL include> placeholders are replaced with user-defined environment variables $MKLPATH and $MKLINCLUDE, respectively. See also examples on linking with ScaLAPACK and Cluster FFT in Chapter 9.

The following examples use the .f Fortran source file. C/C++ users should instead specify a .cpp (C++) or .c (C) file and change the ifort linker to icc.

For assistance in finding the right link line, use the Web-based linking advisor available from http://software.intel.com/en-us/articles/intel-mkl-link-line-advisor.

Linking on Systems Based on the IA-32 Architecture

1. Static linking of myprog.f and parallel Intel MKL:
   ifort myprog.f -L$MKLPATH -I$MKLINCLUDE
   -Wl,--start-group $MKLPATH/libmkl_intel.a
   $MKLPATH/libmkl_intel_thread.a $MKLPATH/libmkl_core.a -Wl,--end-group
   -liomp5 -lpthread

2. Dynamic linking of myprog.f and parallel Intel MKL:
   ifort myprog.f -L$MKLPATH -I$MKLINCLUDE
   -lmkl_intel -lmkl_intel_thread -lmkl_core -liomp5 -lpthread

3. Static linking of myprog.f and sequential version of Intel MKL:
5 Intel® Math Kernel Library User’s Guide

ifort myprog.f -L$MKLPATH -I$MKLINC
-mlmkl_intel_sequential $MKLPATH
-mlmkl_intel $MKLPATH
-mlmkl_sequential $MKLPATH
-mlmkl_core $MKLPATH
-lmpthread

4. Dynamic linking of myprog.f and sequential version of Intel MKL:
   ifort myprog.f -L$MKLPATH -I$MKLINC
   -mlmkl_intel -mlmkl_sequential -mlmkl_core -lmpthread

5. Static linking of myprog.f, Fortran 95 LAPACK interface1, and parallel Intel MKL:
   ifort myprog.f -L$MKLPATH -I$MKLINC -I$MKLINC/32
   -lmkl_intel -lmkl_sequential -lmkl_core $MKLPATH
   -liomp5 -lmpthread

6. Static linking of myprog.f, Fortran 95 BLAS interface1, and parallel Intel MKL:
   ifort myprog.f -L$MKLPATH -I$MKLINC -I$MKLINC/32 -lmkl_blas95
   -lmkl_intel $MKLPATH
   -liomp5 -lmpthread

7. Static linking of myprog.f, parallel version of an iterative sparse solver, and parallel Intel MKL:
   ifort myprog.f -L$MKLPATH -I$MKLINC
   -lmkl_solver $MKLPATH
   -liomp5 -lmpthread

8. Static linking of myprog.f, sequential version of an iterative sparse solver, and sequential Intel MKL:
   ifort myprog.f -L$MKLPATH -I$MKLINC
   -lmkl_solver_sequential $MKLPATH
   -lmpthread

Linking on Systems Based on the Intel® 64 and IA-64 Architectures

1. Static linking of myprog.f and parallel Intel MKL supporting LP64 interface:
   ifort myprog.f -L$MKLPATH -I$MKLINC
   -lmkl_intel_lp64.a $MKLPATH
   -liomp5 -lmpthread

2. Dynamic linking of myprog.f and parallel Intel MKL supporting LP64 interface:

### Building Custom Shared Objects

Custom shared objects enable reducing the collection of functions available in Intel MKL libraries to those required to solve your particular problems, which helps to save disk space and build your own dynamic libraries for distribution.

### Intel MKL Custom Shared Object Builder

Custom shared object builder enables creation of a dynamic library (shared object) containing the selected functions and located in the `tools/builder` directory. The builder contains a makefile and a definition file with the list of functions. The makefile has three targets: `ia32`, `ipf`, and `em64t`. Use the `ia32` target for processors the use the IA-32 architecture; use `ipf` for processors that use the IA-64 architecture; and use `em64t` for processors that use the Intel® 64 architecture.

**NOTE.** The objects in Intel MKL static libraries are position-independent code (PIC), which is not typical for static libraries. Therefore, the custom shared object builder can create a shared object from a subset of Intel MKL functions by picking the respective object files from the static libraries.

### Specifying Makefile Parameters

There are several macros (parameters) for the makefile:

- `export=user_list`
Specifies the full name of the file that contains the list of entry-point functions to be included in the shared object. The default name is user_list (no extension).

name=mkl_custom

Specifies the name of the library to be created. By default, the name of the created library is mkl_custom.so.

xerbla=user_xerbla.o

Specifies the name of the object file that contains the user’s error handler. This error handler will be added to the library and used instead of the default Intel MKL error handler xerbla. If you omit this parameter, the native Intel MKL xerbla is used. See the description of the xerbla function in the Intel MKL Reference Manual on how to develop your own error handler.

MKLROOT=<MKL_directory>

Specifies the location of Intel MKL libraries used to build the custom shared object. The installation directory for the current Intel MKL release is used by default.

All parameters are optional.

In the simplest case, the command line is make ia32, and the missing parameters have default values. This command creates the mkl_custom.so library for processors using the IA-32 architecture. The command takes the list of functions from the user_list file and uses the native Intel MKL error handler xerbla.

An example of a more complex case follows:

make ia32 export=my_func_list.txt name=mkl_small xerbla=my_xerbla.o

In this case, the command creates the mkl_small.so library for processors using the IA-32 architecture. The command takes the list of functions from my_func_list.txt file and uses the user's error handler my_xerbla.o.

The process is similar for processors using the Intel® 64 or IA-64 architecture.

Specifying a List of Functions

Adjust entry points in the user_list file to the required interface. For example, for Fortran functions append an underscore character “_” to the names as a suffix:

dgemm_
ddot_
dgetrf_

If selected functions have several processor-specific versions, they all will be included in the custom library and managed by the dispatcher.
Managing Performance and Memory

This chapter features different ways to obtain the best performance with the Intel® Math Kernel Library (Intel® MKL): primarily, it discusses threading (see Using the Intel® MKL Parallelism), then shows coding techniques and gives hardware configuration tips for improving performance. The chapter also discusses the Intel MKL memory management and shows how to redefine memory functions used by the library.

Using the Intel® MKL Parallelism

Intel MKL is threaded in a number of places:

- Direct sparse solver.
- LAPACK
  - Linear equations, computational routines:

Note that a number of other LAPACK routines, which are based on threaded LAPACK or BLAS routines, make effective use of parallelism: *gesv, *posv, *gels, *gesvd, *syev, *heev, etc.
Level1 and Level2 BLAS functions:
- Level1 BLAS: *axpy, *copy, *swap, ddot/sdot, drot/srot
- Level2 BLAS: *gemv, *trmv, dsyr/ssyr, dsyr2/ssyr2, dsymv/ssymv

Note that these functions are threaded only for:
- Intel® 64 architecture
- Intel® Core™2 Duo and Intel® Core™ i7 processors

- All Level 3 BLAS and all Sparse BLAS routines except Level 2 triangular solvers.
- VML.
- FFT.

Because it is designed for multi-threaded programming, Intel MKL is thread-safe, which means that all Intel MKL functions\(^1\) work correctly during simultaneous execution by multiple threads. In particular, any chunk of threaded Intel MKL code provides access for multiple threads to the same shared data, while permitting only one thread at any given time to access a shared piece of data. Due to thread-safety, you can call Intel MKL from multiple threads and not worry about the function instances interfering with each other.

The library uses OpenMP* threading software, so you can use the environmental variable OMP_NUM_THREADS to specify the number of threads to use. There are different means to set the number of threads. In Intel MKL releases earlier than 10.0, you could use the environment variable OMP_NUM_THREADS (see Setting the Number of Threads Using OpenMP* Environment Variable for details) or the equivalent OpenMP run-time function calls (detailed in section Changing the Number of Threads at Run Time). Starting with version 10.0, Intel MKL also offers variables that are independent of OpenMP, such as MKL_NUM_THREADS, and equivalent Intel MKL functions for thread management (see Using Additional Threading Control for details). The Intel MKL variables are always inspected first, then the OpenMP variables are examined, and if neither are used, the OpenMP software chooses the default number of threads. This is a change from the Intel MKL versions 9.x or lower.

NOTE. Starting with Intel MKL 10.0, the OpenMP* software determines the default number of threads. The default number of threads is equal to the number of logical processors in your system for Intel OpenMP* libraries.

To achieve higher performance, set the number of threads to the number of real processors or physical cores, as summarized in Techniques to Set the Number of Threads.

\(^1\) Except LAPACK deprecated routines ?lacon, ?lasq3, and ?lasq4.
Techniques to Set the Number of Threads

You can employ different techniques to change the number of threads to use in Intel MKL:

- Set one of the OpenMP or Intel MKL environment variables:
  - `OMP_NUM_THREADS`
  - `MKL_NUM_THREADS`
  - `MKL_DOMAIN_NUM_THREADS`

- Call one of the OpenMP or Intel MKL functions:
  - `omp_set_num_threads()`
  - `mkl_set_num_threads()`
  - `mkl_domain_set_num_threads()`

When choosing the appropriate technique, take into account the following rules:

- The Intel MKL threading controls take precedence over the OpenMP techniques.
- A function call takes precedence over any environment variables. The exception, which is a consequence of the previous rule, is the OpenMP subroutine `omp_set_num_threads()`, which does not have precedence over Intel MKL environment variables, such as `MKL_NUM_THREADS`.
- The environment variables cannot be used to change run-time behavior in the course of the run, because they are read only once at the first call to Intel MKL.

Avoiding Conflicts in the Execution Environment

Certain situations can cause conflicts in the execution environment that make the use of threads in Intel MKL problematic. First, this section briefly discusses why the problems exist.

If you thread the program using OpenMP directives and compile the program with Intel® compilers, Intel MKL and the program will both use the same threading library. Intel MKL tries to determine if it is in a parallel region in the program, and if it is, it does not spread its operations over multiple threads unless the user specifically requests Intel MKL to do so via the `MKL_DYNAMIC` functionality (see Using Additional Threading Control for details). However, Intel MKL can be aware that it is in a parallel region only if the threaded program...
and Intel MKL are using the same threading library. If the user’s program is threaded by some other means, Intel MKL may operate in multithreaded mode and the performance may suffer due to overuse of the resources.

Here are several cases with recommendations depending on the threading model you employ:

<table>
<thead>
<tr>
<th>Threading model</th>
<th>Discussion</th>
</tr>
</thead>
<tbody>
<tr>
<td>You thread the program using OS threads (pthreads on the Linux* OS).</td>
<td>If more than one thread calls Intel MKL, and the function being called is threaded, it may be important that you turn off Intel MKL threading. Set the number of threads to one by any of the available means (see Techniques to Set the Number of Threads).</td>
</tr>
<tr>
<td>You thread the program using OpenMP directives and/or pragmas and compile the program using a compiler other than a compiler from Intel.</td>
<td>This is more problematic because setting of the OMP_NUM_THREADS environment variable affects both the compiler's threading library and libiomp (libguide). In this case, choose the threading library that matches the layered Intel MKL with the OpenMP compiler you employ (see Linking Examples on how to do this). If this is not possible, use Intel MKL in the sequential mode. To do this, you should link with the appropriate threading library: libmkl_sequential.a or libmkl_sequential.so (see High-level Directory Structure).</td>
</tr>
<tr>
<td>There are multiple programs running on a multiple-cpu system, for example, a parallelized program that runs using MPI for communication in which each processor is treated as a node.</td>
<td>The threading software will see multiple processors on the system even though each processor has a separate MPI process running on it. In this case, one of the solutions is to set the number of threads to one by any of the available means (see Techniques to Set the Number of Threads). Section Intel® Optimized MP LINPACK Benchmark for Clusters discusses another solution for a Hybrid (OpenMP* + MPI) mode.</td>
</tr>
</tbody>
</table>

See also:

Linking with Compiler Support RTLs.
Setting the Number of Threads Using OpenMP* Environment Variable

You can set the number of threads using the environment variable OMP_NUM_THREADS. To change the number of threads, in the command shell in which the program is going to run, enter:

```
export OMP_NUM_THREADS=<number of threads to use> for certain shells, such as bash.
```

or

```
set OMP_NUM_THREADS=<number of threads to use> for other shells, such as csh or tcsh.
```

See Using Additional Threading Control on how to set the number of threads using Intel MKL environment variables, for example, MKL_NUM_THREADS.

Changing the Number of Threads at Run Time

You cannot change the number of threads during run time using the environment variables. However, you can call OpenMP API functions from your program to change the number of threads during run time. The following sample code shows how to change the number of threads during run time using the omp_set_num_threads() routine. See also Techniques to Set the Number of Threads.

The following example shows both C and Fortran code examples. To run this example in the C language, use the omp.h header file from the Intel® compiler package. If you do not have the Intel compiler but wish to explore the functionality in the example, use Fortran API for omp_set_num_threads() rather than the C version.

Example 6-1 Changing the Number of Threads

```
// ******* C language *******
#include "omp.h"
#include "mkl.h"
#include <stdio.h>

#define SIZE 1000

void main(int args, char *argv[]){

double *a, *b, *c;
a = new double[SIZE*SIZE];
b = new double[SIZE*SIZE];
c = new double[SIZE*SIZE];
```
double alpha=1, beta=1;
int m=SIZE, n=SIZE, k=SIZE, lda=SIZE, ldb=SIZE, ldc=SIZE, i=0, j=0;
char transa='n', transb='n';
for( i=0; i<SIZE; i++){j=0; j<SIZE; j++}{
a[i*SIZE+j]= (double) (i+j);b[i*SIZE+j]= (double) (i*j);c[i*SIZE+j]= (double) 0;
}
cblas_dgemm(CblasRowMajor, CblasNoTrans, CblasNoTrans, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc);
printf("row\ta\tc\n");for ( i=0;i<10;i++){printf("%d:\t%f	%f\n", i, a[i*SIZE], c[i*SIZE]);}
omp_set_num_threads(1);
for( i=0; i<SIZE; i++){j=0; j<SIZE; j++}{
a[i*SIZE+j]= (double) (i+j);b[i*SIZE+j]= (double) (i*j);c[i*SIZE+j]= (double) 0;
}
cblas_dgemm(CblasRowMajor, CblasNoTrans, CblasNoTrans, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc);
printf("row\ta\tc\n");for ( i=0;i<10;i++){printf("%d:\t%f	%f\n", i, a[i*SIZE], c[i*SIZE]);}
omp_set_num_threads(2);
for( i=0; i<SIZE; i++){j=0; j<SIZE; j++}{
a[i*SIZE+j]= (double) (i+j);b[i*SIZE+j]= (double) (i*j);c[i*SIZE+j]= (double) 0;
}
cblas_dgemm(CblasRowMajor, CblasNoTrans, CblasNoTrans, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc);
printf("row\ta\tc\n");for ( i=0;i<10;i++){printf("%d:\t%f	%f\n", i, a[i*SIZE], c[i*SIZE]);}
Example 6-1 Changing the Number of Threads (continued)

```fortran
// ******* Fortran language *******
PROGRAM DGEMM_DIFF_THREADS
INTEGER    N, I, J
PARAMETER  (N=1000)
REAL*8     A(N,N),B(N,N),C(N,N)
REAL*8     ALPHA, BETA
INTEGER*8   MKL_MALLOC
integer   ALLOC_SIZE
integer   NTHRS
ALLOC_SIZE = 8*N*N
A_PTR = MKL_MALLOC(ALLOC_SIZE,128)
B_PTR = MKL_MALLOC(ALLOC_SIZE,128)
C_PTR = MKL_MALLOC(ALLOC_SIZE,128)
ALPHA = 1.1
BETA = -1.2
DO I=1,N
  DO J=1,N
    A(I,J) = I+J
    B(I,J) = I*j
    C(I,J) = 0.0
  END DO
END DO
CALL DGEMM('N','N',N,N,N,ALPHA,A,N,B,N,BETA,C,N)
print *,'Row          A          C'
DO i=1,10
  write(*,'(I4,F20.8,F20.8)') I, A(1,I),C(1,I)
END DO
CALL OMP_SET_NUM_THREADS(1);
DO I=1,N
  DO J=1,N
    A(I,J) = I+J
    B(I,J) = I*j
    C(I,J) = 0.0
  END DO
END DO
```

Example 6-1 Changing the Number of Threads (continued)
Using Additional Threading Control

Intel MKL has new optional threading controls, that is, the new environment variables and service functions. They behave similar to their OpenMP equivalents, but take precedence over them. By using these controls along with OpenMP variables, you can thread the part of the application that does not call Intel MKL and the library independently from each other.

These controls enable you to specify the number of threads for Intel MKL independently of the OpenMP settings. Although Intel MKL may actually use a different number of threads from the number suggested, the controls will also enable you to instruct the library to try using the suggested number when the number used in the calling application is unavailable.
Use of the Intel MKL threading controls in your application is optional. If you do not use them, the library will mainly behave the same way as Intel MKL 9.1 in what relates to threading with the possible exception of a different default number of threads.

Section "Number of User Threads" in the "Fourier Transform Functions" chapter of the Intel MKL Reference Manual shows how the Intel MKL threading controls help to set the number of threads for the FFT computation.

Table 6-2 lists the Intel MKL environment variables for threading control, their equivalent functions, and OMP counterparts:

Table 6-2 Environment Variables for Threading Controls

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Service Function</th>
<th>Comment</th>
<th>Equivalent OpenMP* Environment Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>MKL_NUM_THREADS</td>
<td>mkl_set_num_threads</td>
<td>Suggests the number of threads to use.</td>
<td>OMP_NUM_THREADS</td>
</tr>
<tr>
<td>MKL_DOMAIN_NUM_THREADS</td>
<td>mkl_domain_set_num_threads</td>
<td>Suggests the number of threads for a particular function domain.</td>
<td></td>
</tr>
<tr>
<td>MKL_DYNAMIC</td>
<td>mkl_set_dynamic</td>
<td>Enables Intel MKL to dynamically change the number of threads.</td>
<td>OMP_DYNAMIC</td>
</tr>
</tbody>
</table>

NOTE. The functions take precedence over the respective environment variables. In particular, if in your application, you want Intel MKL to use a given number of threads and do not want users of your application to change this via environment variables, set this number of threads by a call to mkl_set_num_threads(), which will have full precedence over any environment variables being set.
The example below illustrates the use of the Intel MKL function mkl_set_num_threads() to mimic the Intel MKL 9.x default behavior, that is, running on one thread.

**Example 6-2 Setting the Number of Threads to One**

```c
// ******* C language *******
#include <omp.h>
#include <mkl.h>

... mkl_set_num_threads( 1 );
```

```fortran
// ******* Fortran language *******
... call mkl_set_num_threads( 1 )
```

The section further explains the Intel MKL environment variables for threading control. See the Intel MKL Reference Manual for the detailed description of the threading control functions, their parameters, calling syntax, and more code examples.

**MKL_DYNAMIC**

The default value of MKL_DYNAMIC is TRUE, regardless of OMP_DYNAMIC, whose default value may be FALSE.

MKL_DYNAMIC being TRUE means that Intel MKL will always try to pick what it considers the best number of threads, up to the maximum specified by the user.

MKL_DYNAMIC being FALSE means that Intel MKL will normally try not to deviate from the number of threads the user requested. However, setting MKL_DYNAMIC=FALSE does not ensure that Intel MKL will use the number of threads that you request mainly because the library may have no choice on this number for such reasons as system resources. Moreover, the library may examine the problem and pick a different number of threads than the value suggested. For example, if you attempt to do a size 1 matrix-matrix multiply across 8 threads, the library may instead choose to use only one thread because it is impractical to use 8 threads in this event.

Note also that if Intel MKL is called in a parallel region, it will use only one thread by default. If you want the library to use nested parallelism, and the thread within a parallel region is compiled with the same OpenMP compiler as Intel MKL is using, you may experiment with setting MKL_DYNAMIC to FALSE and manually increasing the number of threads.

In general, you should set MKL_DYNAMIC to FALSE only under circumstances that Intel MKL is unable to detect, for example, when nested parallelism is desired where the library is called already from a parallel section.
MKL_DYNAMIC being TRUE, in particular, provides for optimal choice of the number of threads in the following cases:

- If the requested number of threads exceeds the number of physical cores (perhaps because of hyper-threading), and MKL_DYNAMIC is not changed from its default value of TRUE, Intel MKL will scale down the number of threads to the number of physical cores.
- If you are able to detect the presence of MPI, but cannot determine if it has been called in a thread-safe mode (it is impossible to detect this with MPICH 1.2.x, for instance), and MKL_DYNAMIC has not been changed from its default value of TRUE, Intel MKL will run one thread.

**MKL_DOMAIN_NUM_THREADS**

MKL_DOMAIN_NUM_THREADS accepts a string value `<MKL-env-string>`, which must have the following format:

```
<MKL-env-string> ::= <MKL-domain-env-string> { <delimiter>
<MKL-domain-env-string> )
<delimiter> ::= [ <space-symbol>* ] ( <space-symbol> | <comma-symbol> | <semicolon-symbol> | <colon-symbol> ) [ <space-symbol>* ]
<MKL-domain-env-string> ::= <MKL-domain-env-name> <uses>
<number-of-threads> ::= <MKL-domain-env-name> | MKL_ALL | MKL_BLAS | MKL_FFT | MKL_VML
<uses> ::= [ <space-symbol>* ] ( <space-symbol> | <equality-sign> | <comma-symbol> | <semicolon-symbol>) [ <space-symbol>* ]
<number-of-threads> ::= <positive-number>
<positive-number> ::= <decimal-positive-number> | <octal-number> | <hexadecimal-number>
```

In the syntax above, MKL_BLAS indicates the BLAS function domain, MKL_FFT indicates non-cluster FFTs, and MKL_VML indicates the Vector Mathematics Library.

For example,

```
MKL_ALL 2 : MKL_BLAS 1 : MKL_FFT 4
MKL_ALL=2 : MKL_BLAS=1 : MKL_FFT=4
MKL_ALL=2, MKL_BLAS=1, MKL_FFT=4
MKL_ALL = 2 MKL_BLAS 1 , MKL_FFT 4
MKL_ALL,2: MKL_BLAS 1, MKL_FFT,4 .
```
The global variables `MKL_ALL`, `MKL_BLAS`, `MKL_FFT`, and `MKL_VML`, as well as the interface for the Intel MKL threading control functions, can be found in the `mkl.h` header file. Table 6-3 illustrates how values of `MKL_DOMAIN_NUM_THREADS` are interpreted.

<table>
<thead>
<tr>
<th>Value of <code>MKL_DOMAIN_NUM_THREADS</code></th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MKL_ALL=4</code></td>
<td>All parts of Intel MKL are suggested to try using 4 threads. The actual number of threads may be still different because of the <code>MKL_DYNAMIC</code> setting or system resource issues. The setting is equivalent to <code>MKL_NUM_THREADS = 4</code>.</td>
</tr>
<tr>
<td><code>MKL_ALL=1, MKL_BLAS=4</code></td>
<td>All parts of Intel MKL are suggested to use 1 thread, except for BLAS, which is suggested to try 4 threads.</td>
</tr>
<tr>
<td><code>MKL_VML = 2</code></td>
<td>VML is suggested to try 2 threads. The setting affects no other part of Intel MKL.</td>
</tr>
</tbody>
</table>

**NOTE.** The domain-specific settings take precedence over the overall ones. For example, the "MKL_BLAS=4" value of `MKL_DOMAIN_NUM_THREADS` suggests trying 4 threads for BLAS, regardless of later setting `MKL_NUM_THREADS`, and a function call "mkl_domain_set_num_threads (4, MKL_BLAS);" suggests the same, regardless of later calls to mkl_set_num_threads(). However, pay attention to that a function call with input "MKL_ALL", such as "mkl_domain_set_num_threads (4, MKL_ALL);" is equivalent to "mkl_set_num_threads(4)" and thus it will be overwritten by later calls to mkl_set_num_threads. Similarly, the environment setting of `MKL_DOMAIN_NUM_THREADS` with "MKL_ALL=4" will be overwritten with `MKL_NUM_THREADS = 2`.

Whereas the `MKL_DOMAIN_NUM_THREADS` environment variable enables you set several variables at once, for example, "MKL_BLAS=4, MKL_FFT=2", the corresponding function does not take string syntax. So, to do the same with the function calls, you may need to make several calls, which in this example are as follows:

```c
mkl_domain_set_num_threads ( 4, MKL_BLAS );
mkl_domain_set_num_threads ( 2, MKL_FFT );
```
Setting the Environment Variables for Threading Control

To set the environment variables used for threading control, in the command shell in which the program is going to run, enter the `export` or `set` commands, depending on the shell being used. For example, the format for the `export` command used with the bash and other shells is:

```bash
export <VARIABLE NAME>=<value>
```

For example:

```bash
export MKL_NUM_THREADS=4
export MKL_DOMAIN_NUM_THREADS="MKL_ALL=1, MKL_BLAS=4"
export MKL_DYNAMIC=FALSE
```

For other shells, such as csh or tcsh, enter the `set` command.

```csh
set <VARIABLE NAME>=<value>.
```

For example:

```csh
set MKL_NUM_THREADS=4
set MKL_DOMAIN_NUM_THREADS="MKL_ALL=1, MKL_BLAS=4"
set MKL_DYNAMIC=FALSE
```

Dispatching Intel® Advanced Vector Extensions (Intel® AVX)

Intel MKL 10.2 introduced optimized kernels for Intel® AVX. To have the Intel AVX instructions dispatched on Intel AVX-enabled hardware (or simulation), use the Intel MKL service function `mkl_enable_instructions()`. This function enables dispatching new Intel AVX instructions. Call this function before any other Intel MKL function call. For the function description, see the Intel MKL Reference Manual.

**NOTE.** Successful execution of this function does not guarantee new instructions to be dispatched. Dispatching of a particular instruction depends on whether the hardware is Intel AVX-enabled and whether the function is already optimized to dispatch this instruction. However, if you do not call this function, new instructions will not be dispatched.
As the Intel AVX instruction set is evolving, the behavior of 
mkl_enable_instructions() may change with future Intel MKL releases. Refer to the 
Release Notes for release-specific details of the function behavior.

**Tips and Techniques to Improve Performance**

To obtain the best performance with Intel MKL, follow the recommendations given in the 
subsections below.

**Coding Techniques**

To obtain the best performance with Intel MKL, ensure the following data alignment in your 
source code:

- Align arrays at 16-byte boundaries.
- Make sure leading dimension values (n\*element_size) of two-dimensional arrays are 
divisible by 16.
- For two-dimensional arrays, avoid leading dimension values divisible by 2048.

**LAPACK Packed Routines**

The routines with the names that contain the letters HP, OP, PP, SP, TP, UP in the matrix 
type and storage position (the second and third letters respectively) operate on the 
matrices in the packed format (see LAPACK "Routine Naming Conventions" sections in the 
Intel MKL Reference Manual). Their functionality is strictly equivalent to the functionality of 
the unpacked routines with the names containing the letters HE, OR, PO, SY, TR, UN in the 
same positions, but the performance is significantly lower.

If the memory restriction is not too tight, use an unpacked routine for better performance. 
In this case, you need to allocate \(N^2/2\) more memory than the memory required by a 
respective packed routine, where \(N\) is the problem size (the number of equations).

For example, to speed up solving a symmetric eigenproblem with an expert driver by using 
an unpacked routine:

```c
call dsyevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, 
z, ldz, work, lwork, iwork, ifail, info),
```

where \(a\) is the dimension \(lda\)-by-\(n\), which is at least \(N^2\) elements, instead of

```c
call dspevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, 
ldz, work, iwork, ifail, info),
```

where \(ap\) is the dimension \(N*(N+1)/2\).
FFT Functions

Additional conditions can improve performance of the FFT functions.

Applications based on the IA-32 or Intel® 64 architecture. The addresses of the first elements of arrays and the leading dimension values, in bytes ($n \times \text{element\_size}$), of two-dimensional arrays should be divisible by cache line size, which equals:

- 32 bytes for the Intel® Pentium® III processors
- 64 bytes for the Intel® Pentium® 4 processors and processors using Intel® 64 architecture

Applications based on the IA-64 architecture. Leading dimension values, in bytes ($n \times \text{element\_size}$), of two-dimensional arrays are not a power of two.

Hardware Configuration Tips

Dual-Core Intel® Xeon® processor 5100 series systems. To get the best Intel MKL performance on Dual-Core Intel® Xeon® processor 5100 series systems, enable the Hardware DPL (streaming data) Prefetcher functionality of this processor. To configure this functionality, use the appropriate BIOS settings where, as described in your BIOS documentation.

The use of Hyper-Threading Technology. Hyper-Threading Technology (HT Technology) is especially effective when each thread is performing different types of operations and when there are under-utilized resources on the processor. However, Intel MKL fits neither of these criteria because the threaded portions of the library execute at high efficiencies using most of the available resources and perform identical operations on each thread. You may obtain higher performance by disabling HT Technology. See Using the Intel® MKL Parallelism for information on the default number of threads, changing this number, and other relevant details.

If you run with HT enabled, performance may be especially impacted if you run on fewer threads than physical cores. Moreover, if, for example, there are two threads to every physical core, the thread scheduler may assign two threads to some cores and ignore the other ones altogether. If you are using the OpenMP® library of the Intel Compiler, read the respective User Guide on how to best set the thread affinity interface to avoid this situation. For Intel MKL, you are recommended to set

```
KMP_AFFINITY=granularity=fine,compact,1,0.
```
Managing Multi-core Performance

You can obtain best performance on systems with multi-core processors by requiring that threads do not migrate from core to core. To do this, bind threads to the CPU cores by setting an affinity mask to threads. You can do it using any of the following options:

- OpenMP facilities (recommended, if available), for instance, the KMP_AFFINITY environment variable using the Intel OpenMP library
- A system function, as in the example below

Suppose:

- The system has two sockets with two cores each, for a total of 4 cores (CPUs).
- The two-thread parallel application that calls the Intel MKL FFT happens to run faster than in 4 threads, but the performance in 2 threads is very unstable

The C code presented in Example 6-3 solves the problem. The code example calls the system function sched_setaffinity to bind the threads to the cores on different sockets. After that the Intel MKL FFT function is called.

Compile your application with the Intel compiler using the following command:

```bash
icc test_application.c -openmp
```

where `test_application.c` is the filename for the application.

Build the application. Run it in 2 threads, for example, by using the environment variable to set the number of threads:

```bash
env OMP_NUM_THREADS=2 ./a.out
```

---

Example 6-3 Setting An affinity Mask by Operating System Means Using the Intel® Compiler

```c
#include <stdio.h>
#define __USE_GNU
// Set affinity mask
#include <sched.h>
#include <unistd.h>
#include <omp.h>

int main(void) {
    int NCPUs = sysconf(_SC_NPROCESSORS_CONF);
    printf("Using thread affinity on %i NCPUs\n", NCPUs);
    #pragma omp parallel default(shared)
    {
        cpu_set_t new_mask;
        cpu_set_t was_mask;
```
Example 6-3  Setting An affinity Mask by Operating System Means Using the Intel® Compiler
(continued)

```c
int tid = omp_get_thread_num();
CPU_ZERO(&new_mask);
// 2 packages x 2 cores/pkg x 1 threads/core (4 total cores)
CPU_SET(tid==0 ? 0 : 2, &new_mask);
if (sched_getaffinity(0, sizeof(was_mask), &was_mask) == -1) {
    printf("Error: sched_getaffinity(\%d, sizeof(was_mask), &was_mask)\n", tid);
}
if (sched_setaffinity(0, sizeof(new_mask), &new_mask) == -1) {
    printf("Error: sched_setaffinity(\%d, sizeof(new_mask), &new_mask)\n", tid);
}
printf("tid=\%d new_mask=\%08X was_mask=\%08X\n", tid,
       *(unsigned int*)&new_mask, *(unsigned int*)&was_mask);
}
// Call Intel MKL FFT function
return 0;
```

See the Linux Programmer's Manual (in man pages format) for particulars of the sched_setaffinity function used in the above example.

Operating on Denormals

The IEEE 754-2008 standard, "An IEEE Standard for Binary Floating-Point Arithmetic", defines *denormal* (or *subnormal*) numbers as non-zero numbers smaller than the smallest possible normalized numbers for a specific floating-point format. Floating-point operations on denormals are slower than on normalized operands because denormal operands and results are usually handled through a software assist mechanism rather than directly in hardware. This software processing causes Intel MKL functions that consume denormals to run slower than with normalized floating-point numbers.

You can mitigate this performance issue by setting the appropriate bit fields in the MXCSR floating-point control register to flush denormals to zero (FTZ) or to replace any denormals loaded from memory with zero (DAZ). Check your compiler documentation to determine whether it has options to control FTZ and DAZ. Note that these compiler options may slightly affect accuracy.
FFT Optimized Radices

You can improve the performance of Intel MKL FFT if the length of your data vector permits factorization into powers of optimized radices.

In Intel MKL, the optimized radices are 2, 3, 5, 7, and 11.

Using the Intel® MKL Memory Management

Intel MKL has memory management software that controls memory buffers for the use by the library functions. New buffers that the library allocates when your application calls certain functions (Level 3 BLAS or FFT) are not deallocated until the program ends. To get the amount of memory allocated by the memory management software, call the mkl_mem_stat() function. If your program needs to free memory, call mkl_free_buffers(). If another call is made to a library function that needs a memory buffer, the memory manager will again allocate the buffers and they will again remain allocated until either the program ends or the program deallocates the memory.

This behavior facilitates better performance. However, some tools may report this behavior as a memory leak. In addition to calling the mkl_free_buffers() function, you can release (free) memory in your program by setting an environment variable.

The memory management software is turned on by default, which leaves memory allocated by calls to Level 3 BLAS and FFT until the program ends. To disable this behavior of the memory management software, set the MKL_DISABLE_FAST_MM environment variable to any value, which will cause memory to be allocated and freed from call to call. Disabling this feature will negatively impact performance of routines such as the level 3 BLAS, especially for small problem sizes.

Using one of these methods to release memory will not necessarily stop programs from reporting memory leaks, and, in fact, may increase the number of such reports in case you make multiple calls to the library, thereby requiring new allocations with each call. Memory not released by one of the methods described previously will be released by the system when the program ends.

Redefining Memory Functions

C/C++ users of Intel MKL can replace memory functions that the library uses by default with their own ones. The memory renaming feature enables this replacement.

Memory Renaming

Intel MKL memory management by default uses standard C run-time memory functions to allocate or free memory. These functions can be replaced using memory renaming.
Intel MKL accesses the memory functions by pointers `i_malloc`, `i_free`, `i_calloc`, and `i_realloc`, which are visible at the application level. These pointers initially hold addresses of the standard C run-time memory functions `malloc`, `free`, `calloc`, and `realloc`, respectively. You can programmatically redefine values of these pointers to the addresses of your application's memory management functions.

Redirecting the pointers is the only correct way to use your own set of memory management functions. If you call your own memory functions without redirecting the pointers, the memory will get managed by two independent memory management packages, which may cause unexpected memory issues.

**How to Redefine Memory Functions**

To redefine memory functions, use the following procedure:

1. Include the `i_malloc.h` header file in your code. This header file contains all declarations required for an application developer to replace the memory allocation functions. The header file also describes how memory allocation can be replaced in those Intel libraries that support this feature.

2. Redefine values of pointers `i_malloc`, `i_free`, `i_calloc`, `i_realloc` prior to the first call to MKL functions:

Example 6-4  Redefining Memory Functions

```c
#include "i_malloc.h"

i_malloc = my_malloc;
i_calloc = my_calloc;
i_realloc = my_realloc;
i_free = my_free;

// Now you may call Intel MKL functions
```
Language-specific Usage Options

The Intel® Math Kernel Library (Intel® MKL) provides broad support for Fortran and C/C++ programming. However, not all function domains support both Fortran and C interfaces (see Table A-1 in Appendix A). For example, LAPACK has no C interface. You can call functions comprising such domains from C using mixed-language programming.

If you want to use LAPACK or BLAS, which support Fortran, in the Fortran 95 environment, additional effort may be initially required to build compiler-specific interface libraries and modules from the source code provided with Intel MKL.

This chapter mainly focuses on mixed-language programming and the use of language-specific interfaces. It expands upon the use of Intel MKL in C language environments for function domains that provide only Fortran interfaces, as well as explains usage of language-specific interfaces, specifically the Fortran 95 interfaces to LAPACK and BLAS. The chapter also discusses compiler-dependent functions to explain why Fortran 90 modules are supplied as sources. A separate section guides you through the process of running examples to invoke Intel MKL functions from Java*.

Using Language-Specific Interfaces with Intel® MKL

You can create the following interface libraries and modules using the respective makefiles located in the interfaces directory.

<table>

<td>Fortran 95 interface module for LAPACK (LAPACK95), identical to lapack95.mod. To be removed in one of the future releases.</td>
</tr>
</tbody>
</table>
See *Fortran 95 Interfaces to LAPACK and BLAS*, which shows by example how to generate these libraries and modules.

See *Appendix G in the Intel MKL Reference Manual* for details of FFTW to Intel MKL wrappers.

**Fortran 95 Interfaces to LAPACK and BLAS**

Fortran 95 interfaces are compiler-dependent. Intel MKL provides the interface libraries and modules precompiled with the Intel® Fortran compiler. Additionally, the Fortran 95 interfaces and wrappers are delivered as sources. (For more information, see *Compiler-dependent Functions and Fortran 90 Modules*). If you are using a different compiler, build the appropriate library and modules with your compiler and link the library as a user’s library:

1. Go to the respective directory `<mkl_directory>/interfaces/blas95` or `<mkl_directory>/interfaces/lapack95`

2. Type one of the following commands:

   - `make lib32 INSTALL_DIR=<user_dir>` for the IA-32 architecture.
   - `make libem64t [interface=lp64|ilp64] INSTALL_DIR=<user_dir>` for the Intel® 64 architecture.
   - `make lib64 [interface=lp64|ilp64] INSTALL_DIR=<user_dir>` for the IA-64 architecture.

**NOTE.** Parameter `INSTALL_DIR` is required.

As a result, the required library will be built and installed in the `<user_dir>/lib/<arch>` directory, and the .mod files will be built and installed in the `<user_dir>/include/<arch>/{32, em64t, 64}` directory, where `<arch>` is one of `{32, em64t, 64}`.

By default, the ifort compiler is assumed. You may change the compiler command name with an additional parameter of `make FC=<compiler>`.

---

**Table 7-1 Interface Libraries and Modules (continued)**

<table>
<thead>
<tr>
<th>File name</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>mk195_precision.mod¹</td>
<td>Fortran 95 definition of precision parameters for BLAS95 and LAPACK95, identical to f95_precision.mod. To be removed in one of the future releases.</td>
</tr>
</tbody>
</table>

1. Prebuilt for the Intel® Fortran compiler
2. FFTW3 interfaces are integrated with Intel MKL. Look into `<mkl directory>/interfaces/fftw3x*/makefile` for options defining how to build and where to place the standalone library with the wrappers.
For example, command

```
make libem64t FC=pgf95 INSTALL_DIR=<user_pgf95_dir> interface=lp64
```

builds the required library and .mod files and installs them in subdirectories of `<user_pgf95_dir>`.

There is also a way to use the interfaces without building the libraries.

To delete the library from the building directory, use the following commands:

```
make clean32 INSTALL_DIR=<user_dir> for the IA-32 architecture.
make cleanem64t INSTALL_DIR=<user_dir> for the Intel® 64 architecture.
make clean64 INSTALL_DIR=<user_dir> for the IA-64 architecture.
make clean INSTALL_DIR=<user_dir> for all the architectures.
```

**NOTE.** Setting `INSTALL_DIR=../..` or `INSTALL_DIR=<mkl_directory>` in a build or clean command above will replace or delete the Intel MKL prebuilt Fortran 95 library and modules. Though this is possible only if you have administrative rights, you are strongly discouraged from doing this.

### Compiler-dependent Functions and Fortran 90 Modules

Compiler-dependent functions occur whenever the compiler places into the object code function calls that are resolved in its run-time library (RTL). Linking of such code without the appropriate RTL will result in undefined symbols. Intel MKL has been designed to minimize RTL dependencies.

Where dependencies occur, a supporting RTL is shipped with Intel MKL. The only examples of such RTLS, except those that are relevant to the Intel MKL cluster software, are `libiomp` and `libguide`, which are the libraries for the OpenMP* code compiled with an Intel® compiler. Both `libiomp` and `libguide` support the threaded code in Intel MKL.

In other cases where RTL dependencies might arise, the functions are delivered as source code and you need to compile the code with whatever compiler you are using for your application.

In particular, Fortran 90 modules result in the compiler-specific code generation requiring RTL support, so, Intel MKL delivers these modules as source code.
Mixed-language Programming with Intel® MKL

Appendix A lists the programming languages supported for each Intel MKL function domain. However, you can call Intel MKL routines from different language environments. This section explains how to do this using mixed-language programming.

Calling LAPACK, BLAS, and CBLAS Routines from C Language Environments

Not all Intel MKL function domains support both C and Fortran environments. To use Intel MKL Fortran-style functions in C/C++ environments, you should observe certain conventions, which are discussed for LAPACK and BLAS in the subsections below.

WARNING. Avoid calling BLAS95/LAPACK95 from C/C++. Such calls require skills in manipulating the descriptor of a deferred-shape array, which is the Fortran 90 type. Moreover, BLAS95/LAPACK95 routines contain links to a Fortran RTL.

LAPACK

Because LAPACK routines are Fortran-style, when calling them from C-language programs, make sure that you follow the Fortran-style calling conventions:

- Pass variables by *address* as opposed to pass by *value*. Function calls in Example 7-2 and Example 7-3 illustrate this.
- Store your data in Fortran style, that is, column-major rather than row-major order. With row-major order, adopted in C, the last array index changes most quickly and the first one changes most slowly when traversing the memory segment where the array is stored. With Fortran-style column-major order, the last index changes most slowly whereas the first one changes most quickly (as illustrated by Figure 7-1 for a two-dimensional array).
For example, if a two-dimensional matrix A of size $m \times n$ is stored densely in a one-dimensional array B, you can access a matrix element like this:

- In C:
  $$A[i][j] = B[i*n+j] \quad (i=0, \ldots, m-1, \quad j=0, \ldots, n-1)$$
- In Fortran:
  $$A(i,j) = B(j*m+i) \quad (i=1, \ldots, m, \quad j=1, \ldots, n).$$

When calling LAPACK routines from C, be aware that because the Fortran language is case-insensitive, the LAPACK routine names can be both upper-case or lower-case, with or without the trailing underscore. For example, these names are equivalent: dgetrf, DGETRF, dgetrf_, DGETRF_.

**BLAS**

BLAS routines are Fortran-style routines. If you call BLAS routines from a C-language program, you must follow the Fortran-style calling conventions:

- Pass variables by *address* as opposed to passing by *value*
- Store data in Fortran style, that is, column-major rather than row-major order

Refer to the LAPACK section for details of these conventions. See Example 7-2 on how to call BLAS routines from C.

When calling BLAS routines from C, be aware that because the Fortran language is case-insensitive, the BLAS routine names can be both upper-case and lower-case, with or without the trailing underscore. For example, these names are equivalent: dgemm, DGEMM, dgemm_, DGEMM_.

---

**Intel® Math Kernel Library User's Guide**

**Figure 7-1** Column-major Order versus Row-major Order

![Diagram showing column-major order (Fortran-style) and row-major order (C-style)]

A: Column-major order (Fortran-style)  
B: Row-major order (C-style)
CBLAS

Instead of calling BLAS routines from a C-language program, you can use the CBLAS interface.

CBLAS is a C-style interface to the BLAS routines. You can call CBLAS routines using regular C-style calls. When using the CBLAS interface, the header file mkl.h will simplify the program development because it specifies enumerated values as well as prototypes of all the functions. The header determines if the program is being compiled with a C++ compiler, and if it is, the included file will be correct for use with C++ compilation. Example 7-3 illustrates the use of the CBLAS interface.

Using Complex Types in C/C++

As described in the Building Applications document for the Intel® Fortran Compiler, C/C++ does not directly implement the Fortran types COMPLEX(4) and COMPLEX(8). However, you can write equivalent structures. The type COMPLEX(4) consists of two 4-byte floating-point numbers. The first of them is the real-number component, and the second one is the imaginary-number component. The type COMPLEX(8) is similar to COMPLEX(4) except that it contains two 8-byte floating-point numbers.

Intel MKL provides complex types MKL_Complex8 and MKL_Complex16, which are structures equivalent to the Fortran complex types COMPLEX(4) and COMPLEX(8), respectively. These types are defined in the mkl_types.h header file. You can use these types to define complex data. You can also redefine the types with your own types before including the mkl_types.h header file. The only requirement is that the types must be compatible with the Fortran complex layout, that is, the complex type must be a pair of real numbers for the values of real and imaginary parts.

For example, you can use the following definitions in your C++ code:

```c
#define MKL_Complex8 std::complex<float>
and
#define MKL_Complex16 std::complex<double> .
```

See Example 7-2 for details. You can also define these types in the command line:

```
-DMKL_Complex8="std::complex<float>"
-DMKL_Complex16="std::complex<double>".
```
Calling BLAS Functions that Return the Complex Values in C/C++ Code

You must be careful when handling a call from C to a BLAS function that returns complex values. The problem arises because BLAS comprises Fortran functions, and complex values they return are handled quite differently for C and Fortran. However, in addition to normal function calls, Fortran enables calling functions as though they were subroutines, which provides a mechanism for returning the complex value correctly when the function is called from a C program. When a Fortran function is called as a subroutine, the return value is the first parameter in the calling sequence. This feature can be used by the C programmer.

The following example shows how this works.

Normal Fortran function call: \[ \text{result = cdotc( n, x, 1, y, 1 ).} \]

A call to the function as a subroutine: \[ \text{call cdotc( result, n, x, 1, y, 1).} \]

A call to the function from C (notice that the hidden parameter gets exposed): \[ \text{cdotc( \&result, \&n, x, \&one, y, \&one ).} \]

**NOTE.** Intel MKL has both upper-case and lower-case entry points in the Fortran-style (case-insensitive) BLAS, with or without the trailing underscore. So, all these names are equivalent and acceptable: \text{cdotc, CDOTC, cdotc_, CDOTC_}.

The above example shows one of the ways to call several level 1 BLAS functions that return complex values from your C and C++ applications. An easier way is to use the CBLAS interface. For instance, you can call the same function using the CBLAS interface as follows:

\[ \text{cblas_cdotu( n, x, 1, y, 1, \&result )} \]

**NOTE.** The complex value comes last on the argument list in this case.

The following examples show use of the Fortran-style BLAS interface from C and C++, as well as the CBLAS (C language) interface.
The example below illustrates a call from a C program to the complex BLAS Level 1 function \texttt{zdotc()}. This function computes the dot product of two double-precision complex vectors.

In this example, the complex dot product is returned in the structure \texttt{c}.

**Example 7-1 Calling a Complex BLAS Level 1 Function from C**

```c
#include "mkl.h"
#define N 5
void main()
{
    MKL_int n = N, inca = 1, incb = 1, i;
    MKL_Complex16 a[N], b[N], c;
    for( i = 0; i < n; i++ ){
        a[i].re = (double)i; a[i].im = (double)i * 2.0;
        b[i].re = (double)(n - i); b[i].im = (double)i * 2.0;
    }
    zdotc( &c, &n, a, &inca, b, &incb );
    printf( "The complex dot product is: ( %6.2f, %6.2f)\n", c.re, c.im );
}
```
Below is the C++ implementation:

Example 7-2 Calling a Complex BLAS Level 1 Function from C++

```c++
#include <complex>
#include <iostream>
#define MKL_Complex16 std::complex<double>
#include "mkl.h"

#define N 5

int main()
{
    int n, inca = 1, incb = 1, i;
    MKL_Complex16 a[N], b[N], c;
    n = N;
    for( i = 0; i < n; i++ ){
        a[i] = MKL_Complex16(i,i*2.0);
        b[i] = MKL_Complex16(n-i,i*2.0);
    }
    zdotc(&c, &n, a, &inca, b, &incb);
    std::cout << "The complex dot product is: " << c << std::endl;
    return 0;
}
```
The example below uses CBLAS:

**Example 7-3  Using CBLAS Interface Instead of Calling BLAS Directly from C**

```c
#include "mkl.h"
typedef struct{ double re; double im; } complex16;

extern "C" void cblas_zdotc_sub ( const int , const complex16 *,
                                 const int , const complex16 *, const int, const complex16*);

#define N 5

void main()
{

    int n, inca = 1, incb = 1, i;

    complex16 a[N], b[N], c;
    n = N;
    for( i = 0; i < n; i++ ){
        a[i].re = (double)i; a[i].im = (double)i * 2.0;
        b[i].re = (double)(n - i); b[i].im = (double)i * 2.0;
    }
    cblas_zdotc_sub(n, a, inca, b, incb,&c );
    printf( "The complex dot product is: ( %6.2f, %6.2f)\n", c.re, c.im );
}
```

**Support for Boost uBLAS Matrix-matrix Multiplication**

If you are used to uBLAS, you can perform BLAS matrix-matrix multiplication in C++ using Intel MKL substitution of Boost uBLAS functions. uBLAS pertains to the Boost C++ open-source libraries and provides BLAS functionality for dense, packed, and sparse
matrices. The library uses an expression template technique for passing expressions as function arguments, which enables evaluating vector and matrix expressions in one pass without temporary matrices. uBLAS provides two modes:

- **Debug (safe) mode**, default.
  Type and conformance checking is performed.

- **Release (fast) mode**.
  Enabled by the `NDEBUG` preprocessor symbol.

The documentation for the Boost uBLAS is available at www.boost.org/.

Intel MKL provides overloaded `prod()` functions for substituting uBLAS `dense` matrix-matrix multiplication with the Intel MKL `gemm` calls. Though these functions break uBLAS expression templates and introduce temporary matrices, the performance advantage can be considerable for matrix sizes that are not too small (roughly, over 50).

You do not need to change your source code to use the functions. To call them:

- Include the header file `mkl_boost_ublas_matrix_prod.hpp` in your code (from the Intel MKL include directory).

- Add appropriate Intel MKL libraries to the link line (see [Linking Your Application with the Intel® Math Kernel Library](#)).

Only the following expressions are substituted:

```cpp
prod( m1, m2 )
prod( trans(m1), m2 )
prod( trans(conj(m1)), m2 )
prod( conj(trans(m1)), m2 )
prod( m1, trans(m2) )
prod( trans(m1), trans(m2) )
prod( trans(conj(m1)), trans(m2) )
prod( conj(trans(m1)), trans(m2) )
prod( m1, trans(conj(m2)) )
prod( trans(m1), trans(conj(m2)) )
prod( trans(conj(m1)), trans(conj(m2)) )
prod( conj(trans(m1)), trans(conj(m2)) )
prod( m1, conj(trans(m2)) )
prod( trans(m1), conj(trans(m2)) )
prod( trans(conj(m1)), conj(trans(m2)) )
```
prod( conj(trans(m1)), conj(trans(m2)) )

These expressions are substituted in the release mode only (with NDEBUG preprocessor symbol defined). Supported uBLAS versions are Boost 1.34.1, 1.35.0, 1.36.0, and 1.37.0. To get them, visit www.boost.org.

A code example provided in the
<example_directory>/examples/ublas/source/sylvester.cpp file illustrates usage of the Intel MKL uBLAS header file for solving a special case of the Sylvester equation. To run the Intel MKL ublas examples, specify the BOOST_ROOT parameter in the make command, for instance, when using Boost version 1.37.0:

make lib32 BOOST_ROOT=<your_path>/boost_1_37_0

**Invoking Intel® MKL Functions from Java* Applications**

This section describes examples that are provided with the Intel MKL package and illustrate calling the library functions from Java.

**Intel MKL Java Examples**

Java was positioned by its inventor, the Sun Microsystems Corporation as a "Write Once Run Anywhere" (WORA) language. Intel MKL may help to speed-up Java applications, while partially supporting the WORA philosophy, because Intel MKL editions are intended for a wide variety of operating systems and processors including most kinds of laptops and desktops, as well as many workstations and servers.

To demonstrate binding with Java, Intel MKL includes the set of Java examples found in the following directory:

<example_directory>/examples/java .

The examples are provided for the following MKL functions:

- ?gemm, ?gemv, and ?dot families from CBLAS
- The complete set of non-cluster FFT functions
- ESSL®-like functions for one-dimensional convolution and correlation
- VSL Random Number Generators (RNG), except user-defined ones and file subroutines
- VML functions, except GetErrorCallBack, SetErrorCallBack, and ClearErrorCallBack

You can see the example sources in the following directory:

<example_directory>/examples/java/examples .

1. IBM Engineering Scientific Subroutine Library (ESSL®).
The examples are written in Java. They demonstrate usage of the MKL functions with the following variety of data:

- 1- and 2-dimensional data sequences
- real and complex types of the data
- single and double precision

However, note that the wrappers, used in the examples, do not:

- Demonstrate the use of huge arrays (>2 billion elements)
- Demonstrate processing of arrays in native memory
- Check correctness of function parameters
- Demonstrate performance optimizations

To bind with Intel MKL, the examples use the Java Native Interface (JNI* developer framework). The JNI documentation is available from http://java.sun.com/javase/6/docs/technotes/guides/jni/ .

The Java example set includes JNI wrappers that perform the binding. The wrappers do not depend on the examples and may be used in your Java applications. The wrappers for CBLAS, FFT, VML, VSL RNG, and ESSL-like convolution and correlation functions do not depend on each other.

To build the wrappers, just run the examples (see Running the Examples for details). The makefile builds the wrapper binaries. After running the makefile, you can run the examples, which will determine whether the wrappers were built correctly. As a result of running the examples, the following directories will be created in `<mkl directory>/examples/java`:

- docs
- include
- classes
- bin
- _results

The directories docs, include, classes, and bin will contain the wrapper binaries and documentation; the directory _results will contain the testing results.

For a Java programmer, the wrappers look like the following Java classes:

- com.intel.mkl.CBLAS
- com.intel.mkl.DFTI
- com.intel.mkl.ESSL
- com.intel.mkl.VML
- com.intel.mkl.VSL
Documentation for the particular wrapper and example classes will be generated from the Java sources while building and running the examples. To browse the documentation, open the index file in the docs directory (created by the build script):

<mkl directory>/examples/java/docs/index.html.

The Java wrappers for CBLAS, VML, VSL RNG, and FFT establish the interface that directly corresponds to the underlying native functions, so you can refer to the Intel MKL Reference Manual for their functionality and parameters. Interfaces for the ESSL-like functions are described in the generated documentation for the com.intel.mkl.ESSL class.

Each wrapper consists of the interface part for Java and JNI stub written in C. You can find the sources in the following directory:

<mkl directory>/examples/java/wrappers.

Both Java and C parts of the wrapper for CBLAS and VML demonstrate the straightforward approach, which you may use to cover additional CBLAS functions.

The wrapper for FFT is more complicated because it needs to support the lifecycle for FFT descriptor objects. To compute a single Fourier transform, an application needs to call the FFT software several times with the same copy of the native FFT descriptor. The wrapper provides the handler class to hold the native descriptor, while the virtual machine runs Java bytecode.

The wrapper for VSL RNG is similar to the one for FFT. The wrapper provides the handler class to hold the native descriptor of the stream state.

The wrapper for the convolution and correlation functions mitigates the same difficulty of the VSL interface, which assumes a similar lifecycle for "task descriptors". The wrapper utilizes the ESSL-like interface for those functions, which is simpler for the case of 1-dimensional data. The JNI stub additionally encapsulates the MKL functions into the ESSL-like wrappers written in C and so "packs" the lifecycle of a task descriptor into a single call to the native method.

The wrappers meet the JNI Specification versions 1.1 and 5.0 and should work with virtually every modern implementation of Java.

The examples and the Java part of the wrappers are written for the Java language described in "The Java Language Specification (First Edition)" and extended with the feature of "inner classes" (this refers to late 1990s). This level of language version is supported by all versions of the Sun Java Development Kit* (JDK*) developer toolkit and compatible implementations starting from version 1.1.5, or by all modern versions of Java.

The level of C language is "Standard C" (that is, C89) with additional assumptions about integer and floating-point data types required by the Intel MKL interfaces and the JNI header files. That is, the native float and double data types must be the same as JNI jfloat and jdouble data types, respectively, and the native int must be 4 bytes long.
Running the Examples

The Java examples support all the C and C++ compilers that the Intel MKL does. The makefile intended to run the examples also needs the make utility, which is typically provided with the Linux* OS distribution.

To run Java examples, the JDK* developer toolkit is required for compiling and running Java code. A Java implementation must be installed on the computer or available via the network. You may download the JDK from the vendor website.

The examples should work for all versions of JDK. However, they were tested only with the following Java implementations:

- J2SE* SDK 1.4.2, JDK 5.0 and 6.0 from Sun Microsystems, Inc. (http://sun.com)
- JRockit* JDK 1.4.2 and 5.0 from BEA Systems, Inc. (http://bea.com)

NOTE. The implementations from the Sun Microsystems Corporation supports only processors using the IA-32 and Intel® 64 architectures. JRockit* JDK from BEA Systems supports Intel® Itanium® 2 processors as well.

Also note that the Java run-time environment* (JRE*) system, which may be pre-installed on your computer, is not enough. You need the JDK* developer toolkit that supports the following set of tools:

- java
- javac
- javah
- javadoc

To make these tools available for the examples makefile, set the JAVA_HOME environment variable and add the JDK binaries directory to the system PATH, for example, using the bash shell:

```bash
export JAVA_HOME=/home/<user name>/jdk1.5.0_09
export PATH=${JAVA_HOME}/bin:${PATH}
```

You may also need to clear the JDK_HOME environment variable, if it is assigned a value:

```bash
unset JDK_HOME
```

To start the examples, use the makefile found in the Intel MKL Java examples directory:

```bash
make {so32|soem64t|so64|lib32|libem64t|lib64} [function=...] [compiler=...]
```
If you type the `make` command and omit the target (`so32`), the makefile prints the help info, which explains the targets and parameters.

For the examples list, see the `examples.lst` file in the Java examples directory.

**Known Limitations**

There are three kinds of limitations:

- Functionality
- Performance
- Known bugs

**Functionality.** It is possible that some MKL functions will not work if called from the Java environment by using a wrapper, like those provided with the Intel MKL Java examples. Only those specific CBLAS, FFT, VML, VSL RNG, and the convolution/correlation functions listed in the Intel MKL Java Examples section were tested with the Java environment. So, you may use the Java wrappers for these CBLAS, FFT, VML, VSL RNG, and convolution/correlation functions in your Java applications.

**Performance.** The functions from Intel MKL must work faster than similar functions written in pure Java. However, the main goal of these wrappers is to provide code examples, not maximum performance. So, an Intel MKL function called from a Java application will probably work slower than the same function called from a program written in C/C++ or Fortran.

**Known bugs.** There are a number of known bugs in Intel MKL (identified in the Release Notes), as well as incompatibilities between different versions of JDK. The examples and wrappers include workarounds for these problems, so most of the examples work anyway. The source code in the examples and wrappers include comments that describe the workarounds.
This chapter discusses programming with the Intel® Math Kernel Library (Intel® MKL) to provide coding tips that meet certain, specific needs, such as numerical stability. Similarly, Chapter 7 focuses on general language-specific programming options, and Chapter 6 provides tips relevant to performance and memory management.

Aligning Data for Numerical Stability

If linear algebra routines (LAPACK, BLAS) are applied to input data that are bit-for-bit identical but the arrays are aligned differently or the computations are performed either on different platforms or with different numbers of threads, the output may not be bit-for-bit identical, though they will deviate within the appropriate error bounds. The Intel MKL version may also affect numerical stability of the output, as the routines may be implemented differently in different versions. With a given Intel MKL version, the outputs will be bit-for-bit identical provided all the following conditions are met:

- the outputs are obtained on the same platform
- the inputs are bit-for-bit identical
- the input arrays are aligned identically at 16-byte boundaries
- Intel MKL is run in the sequential mode

Unlike the first two conditions, which are under the users' control, the alignment of arrays, by default, is not. For instance, arrays dynamically allocated using malloc are aligned at 8-byte boundaries, not 16-byte boundaries. If you need numerically identical outputs, use mkl_malloc() to get the properly aligned workspace, as shown below:
Example 8-1 Aligning Addresses at 16-byte Boundaries

// ******* C language *******
...
#include <stdlib.h>
...
void *darray;
int workspace;
...
// Allocate workspace aligned on 16-bit boundary
darray = mkl_malloc( sizeof(double)*workspace, 16 );
...
// call the program using MKL
mkl_app( darray );
...
// Free workspace
mkl_free( darray );

! ******* Fortran language *******
...
double precision darray
pointer (p_wrk,darray(1))
integer workspace
...
! Allocate workspace aligned on 16-bit boundary
p_wrk = mkl_malloc( 8*workspace, 16 )
...
! call the program using MKL
call mkl_app( darray )
...
! Free workspace
call mkl_free(p_wrk)
This chapter discusses the usage of the Intel® Math Kernel Library (Intel® MKL) ScaLAPACK and Cluster FFTs, mainly describing linking your application with these domains and including C- and Fortran-specific linking examples. Information on the supported MPI is also discussed.

See Chapter 3 for details about the Intel MKL directory structure, including the available documentation in the doc directory.

For information on MP LINPACK Benchmark for Clusters, see Chapter 11.

Intel MKL ScaLAPACK and Cluster FFTs support MPI implementations identified in the Intel MKL Release Notes.

To link a program that calls ScaLAPACK, you need to know how to link an MPI application first.

Typically, this involves using mpi scripts mpicc or mpif77 (C or FORTRAN 77 scripts) that use the correct MPI header files and others. If, for instance, you are using MPICH installed in /opt/mpich, then typically /opt/mpich/bin/mpicc and /opt/mpich/bin/mpif77 will be the compiler scripts and /opt/mpich/lib/libmpich.a will be the library used for that installation.

## Linking with ScaLAPACK and Cluster FFTs

To link with the Intel MKL ScaLAPACK and/or Cluster FFTs, basically use the following general form:

```
<<MPI> linker script> <files to link> 
-ML<MKL path> [-Wl,--start-group] <MKL Cluster Library> 
<BLACS> <MKL Core Libraries> [-Wl,--end-group]
```

where:

- `<MPI>` is one of several MPI implementations (MPICH, Intel MPI 2.x/3.x, and so on).
<MKL Cluster Library> is one of ScaLAPACK or Cluster FFT libraries for the appropriate architecture, which are listed in Table 3-5, Table 3-6, or Table 3-7. For example, for IA-32 architecture, it is one of -lmkl_scalapack_core or -lmkl_cdft_core.

<BLACS> is one of BLACS libraries for the appropriate architecture, which are listed in Table 3-5, Table 3-6, or Table 3-7. For example, for the IA-32 architecture, it is one of -lmkl_blacs, -lmkl_blacs_intelmpi, or -lmkl_blacs_openmpi.

<MKL Core Libraries> is <MKL LAPACK & MKL kernel libraries> for ScaLAPACK, and <MKL kernel libraries> for Cluster FFTs.

<MKL kernel libraries> are processor optimized kernels, threading library, and system library for threading support linked as described in section Listing Libraries on a Link Line.

<MKL LAPACK & kernel libraries> are the LAPACK library and <MKL kernel libraries>.

Grouping symbols -Wl,--start-group and -Wl,--end-group are required for static linking.

For example, if you are using Intel MPI 3.x and want to statically use the LP64 interface with ScaLAPACK and have only one MPI process per core (and thus do not employ threading), specify the following linker options:

-L$MKLPATH -I$MKLINCLUDE -Wl,--start-group
$MKLPATH/libmkl_scalapack_lp64.a $MKLPATH/libmkl_blacs_intelmpi_lp64.a
$MKLPATH/libmkl_intel_lp64.a $MKLPATH/libmkl_sequential.a
$MKLPATH/libmkl_core.a -static_mpi -Wl,--end-group -lpthread -lm

For more examples, see Examples for Linking with ScaLAPACK and Cluster FFT.

Note that <<MPI> linker script> and <BLACS> library should correspond to the MPI version. For instance, for Intel MPI 3.x, use <Intel MPI 3.x linker script> and libmkl_blacs_intelmpi libraries.

For information on linking with Intel® MKL libraries, see Linking Your Application with the Intel® Math Kernel Library.

Setting the Number of Threads

The OpenMP* software responds to the environmental variable OMP_NUM_THREADS. Intel MKL also has other mechanisms to set the number of threads, such as MKL_NUM_THREADS or MKL_DOMAIN_NUM_THREADS (see Using Additional Threading Control). Make sure that the relevant environment variables have the same and correct values on all the nodes. The Intel MKL versions 10.0 and higher also no longer set the default number of threads to one, but depend on the OpenMP libraries used with the compiler to set the default number. For the threading layer based on the Intel® compiler (libmkl_intel_thread.a), this value is
the number of CPUs according to the OS. Be cautious to avoid over-prescribing the number of threads, which may occur, for instance, when the number of MPI ranks per node and the number of threads per node are both greater than one.

The best way to set an environment variable like `OMP_NUM_THREADS` is your login environment. Remember that `mpirun` starts a fresh default shell on all of the nodes and so, changing this value on the head node and then doing the run (which works on an SMP system) will not effectively change the variable on all the nodes. In `.bashrc`, add a line at the top, as follows:

```
OMP_NUM_THREADS=1; export OMP_NUM_THREADS
```

It is possible to run multiple CPUs per node using MPICH, but the MPICH must be built to allow it. Be aware that certain MPICH applications may not work perfectly in a threaded environment (see the Known Limitations section in the Release Notes). If you encounter problems with MPICH and setting of the number of threads is greater than one, first try setting the number of threads to one and see whether the problem persists.

### Using Shared Libraries

All needed shared libraries must be visible on all the nodes at run time. One way to accomplish this is to point these libraries by the `LD_LIBRARY_PATH` environment variable in the `.bashrc` file. If Intel MKL is installed only on one node, you should link statically when building your Intel MKL applications.

The Intel® compilers or GNU compilers can be used to compile a program that uses Intel MKL. However, make sure that MPI implementation and compiler match up correctly.

### ScaLAPACK Tests

To build NetLib ScaLAPACK tests:

- For the IA-32 architecture, add `libmkl_scalapack_core.a` to your link command.
- For the IA-64 and Intel® 64 architectures, add `libmkl_scalapack_lp64.a` or `libmkl_scalapack_ilp64.a`, depending upon the desired interface.

### Examples for Linking with ScaLAPACK and Cluster FFT

For the detailed information on the structure of the Intel MKL architecture-specific directories and the names of the cluster libraries to link, see [Directory Structure in Detail].
Examples for Linking a C Application

Suppose the following conditions are met:
- MPICH2 1.0.7 or higher is installed in /opt/mpich.
- $MKLPATH$ is a user-defined variable containing $<mkl_directory>/lib/32.$
- You use the Intel® C++ Compiler 9.1 or higher and the main module is in C.

To link with ScaLAPACK for a cluster of systems based on the IA-32 architecture, use the following libraries:

```
$opt/mpich/bin/mpicc <user files to link>  
   -L$MKLPATH  
   -lmkl_scalapack_core  
   -lmkl_blacs_intelmpi  
   -lmkl_lapack  
   -lmkl_intel_intel_thread -lmkl_lapack -lmkl_core  
   -liomp5 -lpthread
```

To link with Cluster FFT for a cluster of systems based on the IA-32 architecture, use the following libraries:

```
$opt/mpich/bin/mpicc <user files to link>  
   $MKLPATH/libmkl_cdft_core.a  
   $MKLPATH/libmkl_blacs_intelmpi.a  
   $MKLPATH/libmkl_intel.a  
   $MKLPATH/libmkl_intel_thread.a  
   $MKLPATH/libmkl_core.a  
   -liomp5 -lpthread
```

Examples for Linking a Fortran Application

Suppose the following conditions are met:
- Intel MPI 3.0 is installed in /opt/intel/mpi/3.0.
- $MKLPATH$ is a user-defined variable containing $<mkl_directory>/lib/64.$
- You use the Intel® Fortran Compiler 9.1 or higher and the main module is in Fortran.

To link with ScaLAPACK for a cluster of systems based on the IA-64 architecture, use the following libraries:

```
/opt/intel/mpi/3.0/bin/mpiifort <user files to link>  
   -L$MKLPATH  
   -lmkl_scalapack_lp64  
   -lmkl_blacs_intelmpi_lp64
```
To link with Cluster FFT for a cluster of systems based on the IA-64 architecture, use the following libraries:

```
/opt/intel/mpi/3.0/bin/mpiifort <user files to link> \
$MKLPATH/libmkl_cdft_core.a \
$MKLPATH/libmkl_blacs_intelmpi_ilp64.a \
$MKLPATH/libmkl_intel_ilp64.a \
$MKLPATH/libmkl_intel_thread.a \
$MKLPATH/libmkl_core.a \
-liomp5 -lpthread
```

A binary linked with ScaLAPACK runs in the same way as any other MPI application (refer to the documentation that comes with the MPI implementation). For instance, the script `mpirun` is used in the case of MPICH2 and OpenMPI, and a number of MPI processes is set by `-np`. In the case of MPICH 2.0 and all Intel MPIs, you should start the daemon before running an application; the execution is driven by the script `mpiexec`.

For further linking examples, see the Intel MKL support website at

Getting Assistance for Programming in the Eclipse* IDE

This chapter discusses features of the Intel® Math Kernel Library (Intel® MKL) which software engineers can benefit from when working in the Eclipse* IDE.

The following features assist programming in the Eclipse IDE:

- The Intel MKL Reference Manual viewable from within the IDE
- Eclipse Help search tuned to target the Intel Web sites
- Context-sensitive help in the Eclipse C/C++ Development Tools (CDT)
- Code/Content Assist in the Eclipse CDT

The first three features are provided by the Intel MKL plugin for Eclipse Help (see Table 3-1 for the plugin location after installation). To use the plugin, place it into the plugins folder of your Eclipse directory.

The last feature is native to the Eclipse CDT. See the Code Assist section in Eclipse* Help

Viewing the Intel® MKL Reference Manual in the Eclipse* IDE

To view the Reference Manual, in Eclipse,
1. Select Help > Help Contents from the menu.
2. In the Help tab, under All Topics, click Intel(R) Math Kernel Library Help
3. In the Help tree that expands, click Intel Math Kernel Library Reference Manual (see Figure 10-1).

The Intel MKL Help Index is also available in Eclipse, and the Reference Manual is included in the Eclipse Help search.
Figure 10-1  Intel® MKL Help in the Eclipse* IDE
Searching the Intel Web Site from the Eclipse* IDE

The Intel MKL plugin tunes Eclipse Help search to target http://www.intel.com so that when you run a search from the Eclipse Help pane, the search hits at the site are shown through a separate link. Figure 10-2 shows search results for "VML Functions" in Eclipse Help. In the figure, 1 hit means an entry hit to the respective site. Click "Intel.com (1 hit)" to open the list of actual hits to the Intel Web site.

Figure 10-2  Hits to the Intel Web Site in the Eclipse* IDE Help Search
You can view context-sensitive help in the Eclipse CDT editor by Infopop windows and F1 Help.

**Infopop Window**

Infopop window is a popup description of a C function.

**NOTE.** In the current release this feature is provided only for VML functions.

To obtain the description of an Intel MKL function whose name is typed in the editor, place the mouse pointer over the function name.

**Figure 10-3  Infopop Window with an Intel® MKL Function Description**

MKLGetVersion d_backward_trig_transform

**Prototype:** void d_backward_trig_transform(double f[], DFTI ipar[], double dpar[], int *stat)

**Description:**

This function computes the backward Trigonometric Transform 

d_backward_trig_transform routine and passed to d_backward

size of the problem n, which determines sizes of the array para

routine with the ipar array and defined in the previously called
**F1 Help**

F1 Help displays the list of relevant documentation topics for a keyword.

To get F1 Help for an Intel MKL function whose name is typed in the editor window,

1. Place the mouse pointer to the function name.
2. Press F1 or double-click the name.
   
   This displays two lists:
   - The list of links to the relevant topics in the product documentation displays in the **Related Topics** page under **See also**. The Intel MK Help Index establishes the relevance (see **Figure 10-4**). Typically, one link displays in this list for each function.
   
   - The list of search results for the function name displays in the **Related Topics** page under **Dynamic Help** (see **Figure 10-5**).
3. Click a link to open the associated Help topic.

**Figure 10-4  F1 Help in the Eclipse* IDE**
Figure 10-5  F1 Help Search in the Eclipse* IDE CDT
This chapter describes the Intel® Optimized LINPACK Benchmark for the Linux® OS (for shared memory systems) and Intel® Optimized MP LINPACK Benchmark for Clusters (for distributed memory systems).

Intel® Optimized LINPACK Benchmark for Linux OS*

Intel® Optimized LINPACK Benchmark is a generalization of the LINPACK 1000 benchmark. It solves a dense (real*8) system of linear equations ($Ax=b$), measures the amount of time it takes to factor and solve the system, converts that time into a performance rate, and tests the results for accuracy. The generalization is in the number of equations ($N$) it can solve, which is not limited to 1000. It uses partial pivoting to assure the accuracy of the results.

This benchmark should not be used to report LINPACK 100 performance, as that is a compiled-code only benchmark. This is a shared memory (SMP) implementation which runs on a single platform. Do not confuse this benchmark with:

- MP LINPACK, which is a distributed memory version of the same benchmark.
- LINPACK, the library, which has been expanded upon by the LAPACK library.

Intel provides optimized versions of the LINPACK benchmarks to help you obtain high LINPACK benchmark results on your systems based on genuine Intel® processors more easily than with the High Performance Linpack (HPL) benchmark. Use this package to benchmark your SMP machine.

Additional information on this software as well as other Intel® software performance products is available at [http://www.intel.com/software/products/](http://www.intel.com/software/products/).

**Contents**

The Intel Optimized LINPACK Benchmark for Linux® contains the following files, located in the `.benchmarks/linpack/` subdirectory in the Intel MKL directory (see Table 3-1):
Table 11-1  Contents of the LINPACK Benchmark

To obtain results for the pre-determined sample problem sizes on a given system, type one of the following, as appropriate:

`)./runme_itanium
`)./runme_xeon32
`)./runme_xeon64

Running the Software

To obtain results for the pre-determined sample problem sizes on a given system, type one of the following, as appropriate:

`)./runme_itanium
`)./runme_xeon32
`)./runme_xeon64
To run the software for other problem sizes, please refer to the extended help included with the program. Extended help can be viewed by running the program executable with the `-e` option:

```
./xlinpack_itanium -e
./xlinpack_xeon32 -e
./xlinpack_xeon64 -e
```

The pre-defined data input files `lininput_itanium`, `lininput_xeon32`, and `lininput_xeon64` are provided merely as examples. Different systems have different number of processors or amount of memory and thus require new input files. The extended help can be used for insight into proper ways to change the sample input files.

Each input file requires at least the following amount of memory:

- `lininput_itanium` 16 GB
- `lininput_xeon32` 2 GB
- `lininput_xeon64` 16 GB

If the system has less memory than the above sample data input requires, you may need to edit or create your own data input files, as explained in the extended help.

Each sample script, in particular, uses the `OMP_NUM_THREADS` environment variable to set the number of processors it is targeting. To optimize performance on a different number of physical processors, change that line appropriately. If you run the Intel Optimized LINPACK Benchmark without setting the number of threads, it will default to the number of cores according to the OS. You can find the settings for this environment variable in the `runme_*` sample scripts. If the settings do not already match the situation for your machine, edit the script.

### Known Limitations

The following limitations are known for the Intel Optimized LINPACK Benchmark for Linux®:

- Intel Optimized LINPACK Benchmark is threaded to effectively use multiple processors. So, in multi-processor systems, best performance will be obtained with Hyper-Threading technology turned off, which ensures that the operating system assigns threads to physical processors only.
- If an incomplete data input file is given, the binaries may either hang or fault. See the sample data input files and/or the extended help for insight into creating a correct data input file.
Intel® Optimized MP LINPACK Benchmark for Clusters

The Intel® Optimized MP LINPACK Benchmark for Clusters is based on modifications and additions to HPL 2.0 from Innovative Computing Laboratories (ICL) at the University of Tennessee, Knoxville (UTK). The Intel Optimized MP LINPACK Benchmark for Clusters can be used for Top 500 runs (see http://www.top500.org). To use the benchmark you need be intimately familiar with the HPL distribution and usage. The Intel Optimized MP LINPACK Benchmark for Clusters provides some additional enhancements and bug fixes designed to make the HPL usage more convenient, as well as explain Intel® MPI settings that may enhance performance. The ./benchmarks/mp_linpack directory adds techniques to minimize search times frequently associated with long runs.

The Intel® Optimized MP LINPACK Benchmark for Clusters is an implementation of the Massively Parallel MP LINPACK benchmark by means of HPL code. It solves a random dense (real*8) system of linear equations (Ax=b), measures the amount of time it takes to factor and solve the system, converts that time into a performance rate, and tests the results for accuracy. You can solve any size (N) system of equations that fit into memory. The benchmark uses full row pivoting to ensure the accuracy of the results.

Use the Intel Optimized MP LINPACK Benchmark for Clusters on a distributed memory machine. On a shared memory machine, use the Intel Optimized LINPACK Benchmark.

Intel provides optimized versions of the LINPACK benchmarks to help you obtain high LINPACK benchmark results on your systems based on genuine Intel® processors more easily than with the HPL benchmark. Use the Intel® Optimized MP LINPACK Benchmark to benchmark your cluster. The prebuilt binaries require that you first install Intel® MPI 3.x be installed on the cluster. The run-time version of Intel MPI is free and can be downloaded from www.intel.com/software/products/cluster.

The Intel package includes software developed at the University of Tennessee, Knoxville, Innovative Computing Laboratories and neither the University nor ICL endorse or promote this product. Although HPL 2.0 is redistributable under certain conditions, this particular package is subject to the Intel MKL license.

Intel MKL has introduced a new functionality into MP LINPACK, which is called a hybrid build, while continuing to support the older version. The term “hybrid” refers to special optimizations added to take advantage of mixed OpenMP*/MPI parallelism. If you want to use one MPI process per node and to achieve further parallelism by means of OpenMP, use the hybrid build. In general, the hybrid build is useful when the number of MPI processes per core is less than one. If you want to rely exclusively on MPI for parallelism and use one MPI per core, use the non-hybrid build.

In addition to supplying certain hybrid prebuilt binaries, Intel MKL supplies some hybrid prebuilt libraries to take advantage of the additional OpenMP* optimizations.
If you wish to use an MPI version other than Intel MPI, you can do so by using the MP LINPACK source provided. You can use the source to build a non-hybrid version that may be used in a hybrid mode, but it would be missing some of the optimizations added to the hybrid version.

Non-hybrid builds are the default of the source code makefiles provided. In some cases, the use of the hybrid mode is required for external reasons. If there is a choice, the non-hybrid code may be faster, although that may change in future releases. To use the non-hybrid code in a hybrid mode, use the threaded version of Intel MKL BLAS, link with a thread-safe MPI, and call function `MPI_init_thread()` so as to indicate a need for MPI to be thread-safe.

Intel MKL also provides prebuilt binaries that are dynamically linked against Intel MPI libraries.

---

**NOTE.** Performance of statically and dynamically linked prebuilt binaries may be different. The performance of both depends on the version of Intel MPI you are using.

You can build binaries statically linked against a particular version of Intel MPI by yourself.

---

**Contents**

The Intel Optimized MP LINPACK Benchmark for Clusters (MP LINPACK Benchmark) includes the HPL 2.0 distribution in its entirety as well as the modifications, delivered in the files listed in Table 11-2 and located in the `./benchmarks/mp_linpack/` subdirectory in the Intel MKL directory (see Table 3-1):

### Building the MP LINPACK

There are a few included sample architecture makefiles. It is recommended that you edit them to fit your specific configuration. In particular:

- Set `TOPdir` to the directory that MP LINPACK is being built in.

</table>
• You may set MPI variables, that is, MPdir, MPinc, and MPlib.
• Specify the location of Intel MKL and of files to be used (LAdir, LAinc, LAlib).
• Adjust compiler and compiler/linker options.
• Specify the version of MP LINPACK you are going to build (hybrid or non-hybrid) by setting the version parameter for the make command, for example:
  make arch=em64t version=hybrid install.

For some sample cases, like Linux systems based on Intel® 64 architecture, the makefiles contain values that must be common. However, you need to be familiar with building an HPL and picking appropriate values for these variables.

New Features

The toolset is basically identical with the HPL 2.0 distribution. There are a few changes that are optionally compiled in and disabled until you specifically request them. These new features are:

**ASYOUGO**: Provides non-intrusive performance information while runs proceed. There are only a few outputs and this information does not impact performance. This is especially useful because many runs can go hours without any information.

**ASYOUGO2**: Provides slightly intrusive additional performance information because it intercepts every DGEMM.

**ASYOUGO2_DISPLAY**: Displays the performance of all the significant DGEMMs inside the run.

**ENDEARLY**: Displays a few performance hints and then terminates the run early.

**FASTSWAP**: Inserts the LAPACK-optimized DLASWP into HPL's code. This may yield a benefit for Itanium® 2 processor. You can experiment with this to determine best results.

**HYBRID**: Establishes the Hybrid OpenMP/MPI mode of MP LINPACK, providing the possibility to use threaded Intel MKL and prebuilt MP LINPACK hybrid libraries.

**WARNING.** Use this option only with an Intel compiler and the Intel® MPI library version 3.1 or higher. You are also recommended to use the compiler version 10.0 or higher.
Benchmarking a Cluster

To benchmark a cluster, follow the sequence of steps below (some of them are optional). Pay special attention to the iterative steps 3 and 4. They make a loop that searches for HPL parameters (specified in HPL.dat) that enable you to reach the top performance of your cluster.

1. Install HPL and make sure HPL is functional on all the nodes.
2. You may run nodeperf.c (included in the distribution) to see the performance of DGEMM on all the nodes.
   Compile nodeperf.c with your MPI and Intel MKL. For example:
   ```
   mpiicc -O3 nodeperf.c -L$MKLPATH $MKLPATH/libmkl_intel_lp64.a -L$MKLPATH/libmkl_sequential.a -Wl,--start-group $MKLPATH/libmkl_core.a -Wl,--end-group -lpthread .
   ```
   Launching nodeperf.c on all the nodes is especially helpful in a very large cluster. Indeed, there may be a stray job on a certain node, for example, 738, which is running 5% slower than the rest. MP LINPACK will then run as slow as the slowest node. In this case, nodeperf enables quick identification of the potential problem spot without numerous small MP LINPACK runs around the cluster in search of the bad node. It is common that after a bunch of HPL runs, there may be zombie processes and nodeperf facilitates finding the slow nodes. It goes through all the nodes, one at a time, and reports the performance of DGEMM followed by some host identifier. Therefore, the higher the DGEMM performance, the faster that node was performing.
3. Edit HPL.dat to fit your cluster needs.
   Read through the HPL documentation for ideas on this. However, you should try on at least 4 nodes.
4. Make an HPL run, using compile options such as ASYOGO or ASYOG02 or ENDEARLY to aid in your search (These options enable you to gain insight into the performance sooner than HPL would normally give this insight.)
   When doing so, follow these recommendations:
— Use MP LINPACK, which is a patched version of HPL, to save time in the search. Using a patched version of HPL should not hinder your performance. That’s why features that could be performance intrusive are compile-optional (and it is explained below) in MP LINPACK. That is, if you do not use the new options explained in section Options to Reduce Search Time, then these changes are disabled. The primary purpose of the additions is to assist you in finding solutions. HPL requires a long time to search for many different parameters. In the MP LINPACK, the goal is to get the best possible number. Given that the input is not fixed, there is a large parameter space you must search over. In fact, an exhaustive search of all possible inputs is improbably large even for a powerful cluster.

This patched version of HPL optionally prints information on performance as it proceeds, or even terminates early depending on your desires.

— Save time by compiling with –DENDEARLY –DASYOUGO2 (described in the Options to Reduce Search Time section) and using a negative threshold (do not use a negative threshold on the final run that you intend to submit as a Top500 entry). You can set the threshold in line 13 of the HPL 2.0 input file HPL.dat.

— If you are going to run a problem to completion, do it with –DASYOUGO (see Options to Reduce Search Time).

5. Using the quick performance feedback, return to step 3 and iterate until you are sure that the performance is as good as possible.

**Options to Reduce Search Time**

Running huge problems to completion on large numbers of nodes can take many hours. The search space for MP LINPACK is also huge: not only can you run any size problem, but over a number of block sizes, grid layouts, lookahead steps, using different factorization methods, etc. It can be a large waste of time to run a huge problem to completion only to discover it ran 0.01% slower than your previous best problem.

There are 3 options you might want to experiment with to reduce the search time:

- –DASYOUGO
- –DENDEARLY
- –DASYOUGO2

Use –DASYOUGO2 cautiously because it does have a marginal performance impact. To see DGEMM internal performance, compile with –DASYOUGO2 and –DASYOUGO2_DISPLAY. These options provide a lot of useful DGEMM performance information at the cost of around 0.2% performance loss.

If you want to use the old HPL, simply omit these options and recompile from scratch (try "make arch=<arch> clean_arch_all").
-DASYOUGO: Gives performance data as the run proceeds. The performance always starts off higher and then drops because this actually happens in LU decomposition. The ASYOGUO performance estimate is usually an overestimate (because LU slows down as it goes), but it gets more accurate as the problem proceeds. The greater the lookahead step, the less accurate the first number may be. ASYOGUO tries to estimate where one is in the LU decomposition that MP LINPACK performs and this is always an overestimate as compared to ASYOGUO2, which measures actually achieved DGEMM performance. Note that the ASYOGUO output is a subset of the information that ASYOGUO2 provides. So, refer to the description of the –DASYOGUO2 option below for the details of the output.

-DENDEARLY: Terminates the problem after a few steps, so that you can set up 10 or 20 HPL runs without monitoring them, see how they all do, and then only run the fastest ones to completion. -DENDEARLY assumes –DASYOUGO. You do not need to define both, although it doesn’t hurt. Because the problem terminates early, it is recommended setting the “threshold” parameter in HPL.dat to a negative number when testing ENDEARLY. There is no point in doing a residual check if the problem ended early. It also sometimes gives a better picture to compile with –DASYOGUO2 when using –DENDEARLY. Usage notes on –DENDEARLY follow:

— –DENDEARLY stops the problem after a few iterations of DGEMM on the blocksize (the bigger the blocksize, the further it gets). It prints only 5 or 6 “updates”, whereas –DASYOUGO prints about 46 or so output elements before the problem completes.

— Performance for –DASYOUGO and –DENDEARLY always starts off at one speed, slowly increases, and then slows down toward the end (because that is what LU does). –DENDEARLY is likely to terminate before it starts to slow down.

— –DENDEARLY terminates the problem early with an HPL Error exit. It means that you need to ignore the missing residual results, which are wrong, as the problem never completed. However, you can get an idea what the initial performance was, and if it looks good, then run the problem to completion without –DENDEARLY. To avoid the error check, you can set HPL’s threshold parameter in HPL.dat to a negative number.

— Though –DENDEARLY terminates early, HPL treats the problem as completed and computes Gflop rating as though the problem ran to completion. Ignore this erroneously high rating.

— The bigger the problem, the more accurately the last update that –DENDEARLY returns will be close to what happens when the problem runs to completion. –DENDEARLY is a poor approximation for small problems. It is for this reason that you are suggested to use ENDEARLY in conjunction with ASYOGUO2, because ASYOGUO2 reports actual DGEMM performance, which can be a closer approximation to problems just starting. The best known compile options for Itanium® 2 processor are with the Intel® compiler:

-02 -ipo -ipo_obj -ftz -IPF_fltacc -IPF_fma -unroll -w -tpp2
-**DASYOUGO2**: Gives detailed single-node **DGEMM** performance information. It captures all **DGEMM** calls (if you use Fortran BLAS) and records their data. Because of this, the routine has a marginal intrusive overhead. Unlike -**DASYOUGO**, which is quite non-intrusive, -**DASYOUGO2** is interrupting every **DGEMM** call to monitor its performance. You should beware of this overhead, although for big problems, it is, for sure, less than 1/10th of a percent.

Here is a sample **ASYOUGO2** output (the first 3 non-intrusive numbers can be found in **ASYOUGO** and **ENDEARLY**), so it suffices to describe these numbers here:

Col=001280 Fract=0.050 Mflops=42454.99 (DT= 9.5 DF= 34.1 DMF=38322.78).

The problem size was \( N=16000 \) with a blocksize of 128. After 10 blocks, that is, 1280 columns, an output was sent to the screen. Here, the fraction of columns completed is 1280/16000=0.08. Only up to 40 outputs are printed, at various places through the matrix decomposition: fractions

0.005 0.010 0.015 0.020 0.025 0.030 0.035 0.040 0.045 0.050 0.055 0.060 0.065 0.070 0.075 0.080 0.085 0.090 0.095 0.100 0.105 0.110 0.115 0.120 0.125 0.130 0.135 0.140 0.145 0.150 0.155 0.160 0.165 0.170 0.175 0.180 0.185 0.190 0.195 0.200 0.205 0.210 0.215 0.220 0.225 0.230 0.235 0.240 0.245 0.250 0.255 0.260 0.265 0.270 0.275 0.280 0.285 0.290 0.295 0.300 0.305 0.310 0.315 0.320 0.325 0.330 0.335 0.340 0.345 0.350 0.355 0.360 0.365 0.370 0.375 0.380 0.385 0.390 0.395 0.400 0.405 0.410 0.415 0.420 0.425 0.430 0.435 0.440 0.445 0.450 0.455 0.460 0.465 0.470 0.475 0.480 0.485 0.490 0.495 0.505 0.515 0.525 0.535 0.555 0.575 0.595 0.615 0.635 0.655 0.675 0.695 0.795 0.895.

However, this problem size is so small and the block size so big by comparison that as soon as it prints the value for 0.045, it was already through 0.08 fraction of the columns. On a really big problem, the fractional number will be more accurate. It never prints more than the 112 numbers above. So, smaller problems will have fewer than 112 updates, and the biggest problems will have precisely 112 updates.

The **Mflops** is an estimate based on 1280 columns of LU being completed. However, with lookahead steps, sometimes that work is not actually completed when the output is made. Nevertheless, this is a good estimate for comparing identical runs.

The 3 numbers in parenthesis are intrusive **ASYOUGO2** addins. The **DT** is the total time processor 0 has spent in **DGEMM**. The **DF** is the number of billion operations that have been performed in **DGEMM** by one processor. Hence, the performance of processor 0 (in Gflops) in **DGEMM** is always \( \text{DF}/\text{DT} \). Using the number of **DGEMM** flops as a basis instead of the number of LU flops, you get a lower bound on performance of our run by looking at **DMF**, which can be compared to **Mflops** above (It uses the global LU time, but the **DGEMM** flops are computed under the assumption that the problem is evenly distributed amongst the nodes, as only HPL’s node (0,0) returns any output.)

Note that when using the above performance monitoring tools to compare different **HPL.dat** input data sets, you should beware that the pattern of performance drop off that LU experiences is sensitive to some input data. For instance, when you try very small problems, the performance drop off from the initial values to end values is very rapid. The larger the problem, the less the drop off, and it is probably safe to use the first few
performance values to estimate the difference between a problem size 700000 and 701000, for instance. Another factor that influences the performance drop off is the grid dimensions (P and Q). For big problems, the performance tends to fall off less from the first few steps when P and Q are roughly equal in value. You can make use of a large number of parameters, such as broadcast types, and change them so that the final performance is determined very closely by the first few steps.

Using these tools will greatly assist the amount of data you can test.
Table A-1 shows language interfaces that Intel® Math Kernel Library (Intel® MKL) provides for each function domain, and Table A-2 lists the respective header files. However, Intel MKL routines can be called from other languages using mixed-language programming. For example, see Mixed-language Programming with Intel® MKL on how to call Fortran routines from C/C++.

Support for Third-Party Interfaces

This appendix describes in brief certain interfaces that Intel® Math Kernel Library (Intel® MKL) supports.

GMP* Functions

Intel MKL implementation of GMP* arithmetic functions includes arbitrary precision arithmetic operations on integer numbers. The interfaces of such functions fully match the GNU Multiple Precision* (GMP) Arithmetic Library. For specifications of these functions, please see http://www.intel.com/software/products/mkl/docs/gnump/WebHelp/.

If you currently use the GMP* library, you need to modify INCLUDE statements in your programs to mkl_gmp.h.

FFTW Interface Support

Intel MKL offers two collections of wrappers being the FFTW interface (www.fftw.org) superstructure to be used for calling the Intel MKL Fourier transform functions. These collections correspond to the FFTW versions 2.x and 3.x and the Intel MKL versions 7.0 and later.

These wrappers enable developers whose programs currently use FFTW to gain performance with the Intel MKL Fourier transforms without changing the program source code. See the "FFTW to Intel® MKL Wrappers" appendix in the Intel MKL Reference Manual for details on the use of the wrappers.
